"I began by stating that I was very glad to be present on the occasion, and to do honor to Prof. Langley, whose work, in my opinion, had been of the highest importance to the problem of aerial flight; and by aerial flight I did not mean the moving about in the air of a dirigible balloon; for it seems to me that a gas-bag (however well arranged or braced) will always be at the mercy of the winds. If speeds of 100 to 150 miles an hour are ever to be attained in flight (and they should be attained to make aerial flight worth while) then the gas-bag must be left out of it, and we must rely upon the support of the air as a bird relies upon it.

"Looking at the subject from the standpoint of an engineer, it seems to me that when Dr. Langley constructed his original aerodrome which flew—the machine having within itself propelling machinery which could support itself in the air, and even rise in the air—he had solved the problem of aerial flight, from a mechanical standpoint. The small aerodrome of Prof. Langley (it was stated) had made numerous trips without difficulty; and surely it makes no difference to the problem whether it carried live freight or not. Who could doubt that a larger machine would have carried a man? It probably would have alighted with no greater difficulty. Nature has, in the bird, produced a mechanism for flying which it is not necessary that man should copy, any more than man should make his automobile with legs and feet, or his steamship with fins.

"The ideal machine must, however, have some of the bird's qualities. It will be noticed that the feathers of a bird have been evolved so that within these feathers a film of air may be carried by the bird, giving the result that in flying air is really moving upon air, resulting, as nearly as possible, in the absence of friction, which is the real obstacle calling for the expenditure of power. The feathers of the bird, also, by their yielding character and open structure practically reduce eddies to a minimum by conforming to the stream lines. The provision of the bird's feathers corresponds in function with that other most perfect covering for a fish, its body being covered with a gelatinous film, something which is as nearly like water as is possible, but is not washed off by the water; the result being that in the fish's motion there is almost (if not quite) a motion of one liquid upon another, with the elimination of much of the resistance encountered. Here again the long, tapering body of the fish, and the delicate tail and fins, result in conforming to the relative motion of the water alongside, and the elimination of eddies which consume power.

"The ideal machine for flying is necessarily, it seems to me, of the nature of a kite, which, instead of having a string to hold it up on the air, is pushed through the air by means of propellers, as in Prof. Langley's aerodrome and other similar machines. Obviously, it is here that a very light engine for its output in power will be needed. Dr. Langley has said that he has succeeded in obtaining an engine which did not require to weigh more than four or five pounds to the horse-power.

"It would be out of place here to speak of the commercial possibilities of the flying machine. It seems to me that it will naturally be a machine for emergency work; a most effective war engine, for example, and by a war engine I, of course, mean a peace engine. The more effective it is, the less likelihood there is of war being declared; and the menace of a sudden visit by a flying enemy would probably have the result of making those who declare war but do not fight the battles a little more cautious as to such declaration.

"We must not be impatient as to unavoidable accidents in the pioneer work of flying. There are undoubtedly difficulties yet to be overcome in launching the airship, and in alighting with it safely in all cases. A child may have the muscles and necessary organization permitting it to walk, but it will have to learn to walk; to co-ordinate its muscular actions and balance the nervous impulses. Even the young bird, on leaving the nest, is by no means an expert at flying until it has practised or learned the art. In the same way, given a machine which is controllable and which is able to fly, a machine perfect in every particular, it will be necessary even then for the operator to learn to manipulate it, just as one learns to manipulate a bicycle, i. e., to do the right thing, and not the wrong thing, on occasion.

"I have confidence that before many years we shall have operative machines which can traverse the air. I do not consider them, however, as substitutes for steamships, for freight trains, or even for passenger trains; their field being supplementary to these agencies, adding to our capabilities already mentioned another means of our getting about. The danger of collision in the air would, it seems to me, be less than on the surface of the earth, as there is room to pass not only to the right or to the left, but above and below. We are not confined to a road or a track, but we may count on two or three miles deep of air as the common highway. Man has accomplished so much in the past 100 years that it will not do to be pessimistic as to the possibilities of the future."

Electrical Words Wanted.

The *St. James Gazette*, of London, calls the attention of professional neologists to the pressing need of some new verbs. "We want," it says, "popular verbs for several operations introduced by modern science. The X-rays, the Finsen treatment for lupus, the operation of radium for cancer, and what not—what are the words for these? A man is guillotined or hanged; his leg is amputated; he is trepanned. What is it when he is rayed, Finsened, radiumed? We still want a wireless word. 'Marconigram,' which was suggested, seems to have died a natural death. What is the synonym for telephone when one speaks over the instrument to which a phonograph is attached? And have we finally agreed that 'motor' is the verb to travel by automobile?"

Speed-Torque Characteristics of the Single-Phase Repulsion Motor.

In opening his paper with the above title, read last week before the American Institute of Electrical Engineers, Mr. Walter I. Slichter said that for some months past he has been in charge of a series of experiments with various types of alternating-current motors, during which much attention was given to alternating-current commutator motors. The repulsion motor resembles very much a regular direct-current armature in an induction-motor field. The resemblance to the induction motor is carried still further in that there is no electrical connection between the primary and secondary. This makes it possible to wind the primary for a high line voltage, while the voltage of the secondary winding is chosen at such a value as may be commutated satisfactorily, since it is short circuited on itself through its brushes.

The motor has the same characteristics as the direct-current series motor; namely, maximum torque at starting, increasing torque with increasing current and decreasing speed, and comparatively constant efficiency through a wide range of speed. The maximum speed of the motor is limited only by the load and impressed voltage and has no relation to the synchronous speed.

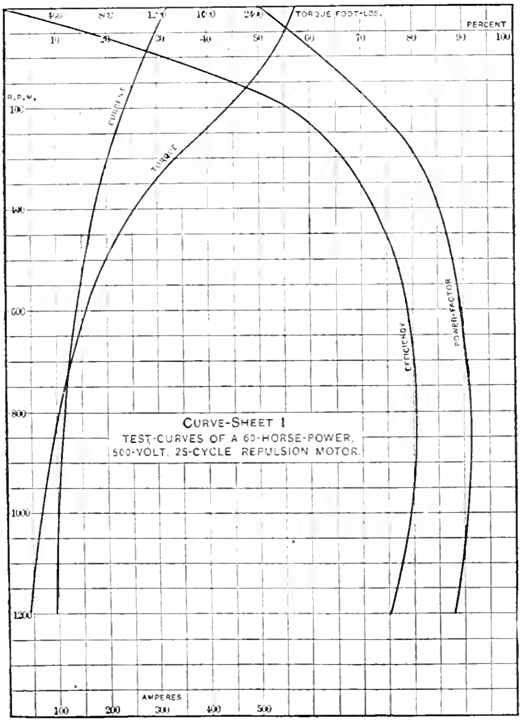

FIG. 1.—TEST CURVES OF 60-HP REPULSION MOTOR.

Due to the reactance of the motor circuits, the power-factor at starting is low and will be with any alternating-current motor; but in the repulsion motor a low power-factor does not mean small torque. On the contrary, the maximum torque occurs simultaneously with the lowest power-factor; that is, at starting. The power-factor of the repulsion motor rises very rapidly with the speed; it reaches a good value at one-third synchronous speed, and values near to 90 per cent. are obtained over a considerable range of speed. For this reason a large number of poles is not necessary and frequencies of 25, 40 and even 60 cycles may be employed.

The rotating conductors of the secondary cutting the primary flux, generate a leading e.m.f., which causes a leading current to flow therein and gives the high power-factor of the motor. In the plain repulsion motor, this leading current never reaches a value great enough to compensate entirely for the magnetizing and other wattless currents at available speeds, but the phenomenon is utilized to obtain unity power-factor in the compensated type by the addition of a second circuit. The inherently good power-factor of the repulsion motor makes it possible to use larger clearance between field and armature than is permitted in induction motors, thus greatly increasing its value in railway work where comparatively large air-gaps are necessary.

The curves given are partly from test and partly from calculation of motors having air-gaps on a side of ⅛ inch and more. The air-gap of corresponding stationary induction motors would be .040 inch and more. The efficiency, while not so good as in a direct-current motor, is yet very good, reaching values of from 80 to 85, including gear-loss for sizes ranging from 50 to 200 horse-power.

Commutation at normal speeds is inherently good, due to the revolving field. As the speed decreases, the current increases rapidly, producing a tendency to spark, but with the reduced voltage of starting the rush of current is limited to values within the range of good commutation, as in the direct-current motor. At higher speeds, ranging above one and a half times synchronism, the frequency of commutation becomes high and sparking appears.

The motor of Curve-Sheet 1 (Fig. 1) will start with 75 per cent. of full voltage and twice full-load current with no trouble from sparking. As these curves are prepared upon a railway-motor basis, and full-load current will produce a rise of 75° C. after one hour's run, the ability of the repulsion motor successfully to commutate overloads is equal to that of the direct-current series motor; in fact, better, due to the short-circuited commutator which makes flashing-over impossible.

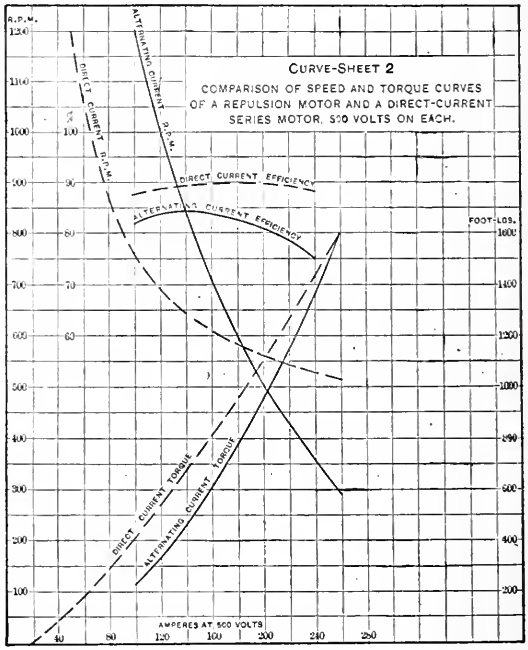

FIG. 2.—CURVES OF REPULSION AND DIRECT-CURRENT MOTORS.

Curve-Sheet 1 (Fig. 1) shows the characteristics of a repulsion motor plotted with revolutions per minute as a base. These curves are taken from tests on a 60-hp, 25-cycle, 500-volt motor; they show the rapidly rising efficiency and power-factor and the large torque at starting. The starting torque is 2,300 ft. lbs., with an input of 325 amperes, and the normal torque during acceleration, 450 ft. lbs. at 750 revolutions and 125 amperes. Thus the starting torque is five times normal and the starting current 2.6 times normal; or the torque per ampere at starting is 1.92 times what it is at normal speed, should occasion demand the full starting capacity of the motor.

This statement gives an idea of the steep speed-characteristics of the motor, which are even better shown in Curve-Sheet 2 (Fig. 2). The full lines refer to a later type of repulsion motor and the broken lines to a standard direct-current series railway motor; these curves are plotted in the usual way with current as a base. This shows that the torque increases more rapidly with increasing current in the repulsion motor than in the series; and conversely that the speed of the repulsion motor increases more rapidly with decreasing current than in the series motor. Efficiency, including gear-loss, is given and is 84.5 per cent. at the maximum for the alternating-current motor. This motor was designed with the steep speed-characteristics for acceleration work, while the motor of Curve-Sheet 4 (Fig. 4) is designed for constant-speed running and has not such steep curves but better constants at light loads.

The characteristics show the repulsion motor to be admirably adapted for acceleration work, the efficiency of acceleration being higher than in direct-current work, due to the possibility of obtaining fractional e.m.f's with alternating currents without introducing the dead resistance losses of the direct-current system of control.

This is shown in the curves on Curve-Sheet 3 (Fig. 3) which gives the acceleration curves from test of a 25-ton car equipped with two 60-hp repulsion motors. The full lines indicate the repulsion motor characteristics and the broken lines those calculated for a direct-current equipment. The gearing is chosen for the same free running speed, 33 miles per hour, the same average acceleration and the same distance covered in sixty seconds. For the direct-current motor the curve of wilowatts input, miles per hour, and miles traveled, are given as calculated; and for the alternating-current motor the kilovolt-ampere input, kilowatt input, miles per hour, and miles traveled, from test.

The repulsion motor remains on the controller only sixteen seconds and the direct-current motor 25 seconds. The maximum power taken by the direct-current motor is 70 kw and by the repulsion motor 61 kw or 67 kilovolt-amperes. At the end of 25 seconds, the total kw-hour input in the two cases is .375 for the direct current and .30 for the alternating current. At the end of 60 seconds both cars have covered a distance of .039 mile and have reached practically the same speed of 32.5 miles per hour, the kw-hour input being .72 for the direct current and .685 for the alternating current.

By comparing the areas of the kilowatt curves in the two cases the gain or rather the saving by the use of the alternating current is readily seen. It is also worthy of note that the volt-ampere input of the alternating-current motor is least at starting; that is, the line current is least. As this is the time at which the power-factor

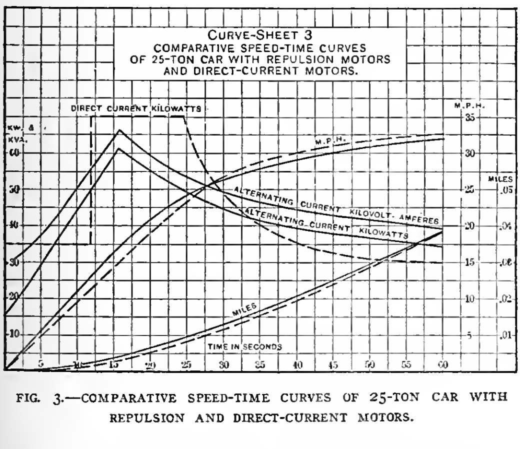

FIG. 3.—COMPARATIVE SPEED-TIME CURVES OF 25-TON CAR WITH REPULSION AND DIRECT-CURRENT MOTORS.

is lowest, it is seen that the effect of the low power-factor on the regulation of the system is much modified by the small value of the current.

Curve-Sheet 4 (Fig. 4) shows the calculated characteristics of a 175-hp railway repulsion motor having an air-gap of .15 inch and wound for 1,500 volts and 25 cycles. The efficiency, including gear-loss, is 85 per cent. at the maximum and the power-factor is 93. Such a motor is designed for heavy, slow-speed locomotive work, which is probably one of the most promising fields for the alternating-current motor. It is readily seen how well it is adapted for freight haulage by the fact that the efficiency of 85 per cent. is attained at a speed as low as 500 revolutions, thus permitting a speed of 12 to 15 miles per hour, with a good gear reduction.

Thus the repulsion motor is well adapted for acceleration work as well as for efficient running at light loads, and having good constants at low speeds is well adapted for freight haulage at low speeds.

The curves given in the paper all refer to the simple repulsion motor, the theory of which is given in a paper read at the same meeting by Mr. C. P. Steinmetz, printed elsewhere in abstract in this issue. There are many variations of the repulsion motor, more or less complicated, from which a better power-factor and even a

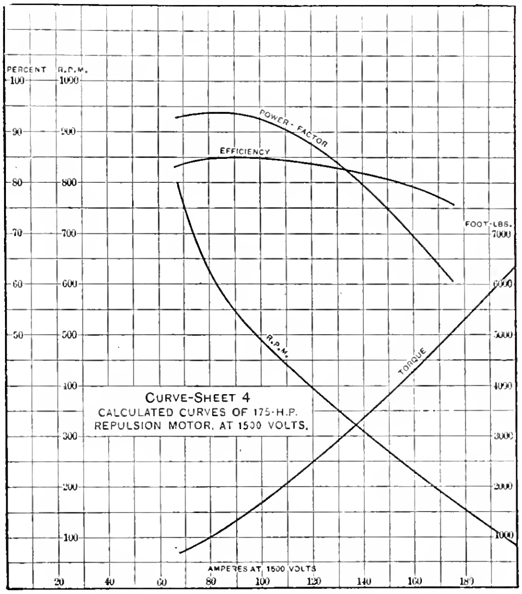

FIG. 4.—CALCULATED CHARACTERISTICS OF A 175-HP, 1,500-VOLT REPULSION MOTOR.

better efficiency have been obtained in test, but Mr. Schlecter said that a description of these various schemes with their characteristics would require sufficient space to warrant a distinct paper and intimated that such a paper would be presented before the Institute at some future date.

Electric Traction in Cuba.

Mr. Max J. Baehr, the United States Consul at Cienfuegos, Cuba, says: "Cienfuegos has railway communication with Habana, Matanzas, Cardenas, Sagua la Grande and Caibarien on the north coast, with Santa Clara in the interior, and thence, since the completion of the new Cuban Central Railroad, with Santiago.

"A project is now under consideration by local and American capitalists for the construction of an electric railway extending from this city into the interior, a distance of 30 miles or more, which would give rapid transit between Cienfuegos and several important villages in the sugar-producing belt, these towns now having very inadequate communication with this port. I am credibly informed that a company has been organized to carry the project into effect, that a charter has been applied for and obtained, and that only a short time will elapse before the beginning of active work on the grading of the road. If this enterprise is carried to fulfillment, as seems reasonably certain, it will not only give employment to a large number of laborers who now find steady work only during the sugar-grinding season, but will contribute in no small degree to the material upbuilding of this section of Cuba.

"For the information of American dealers in electric and railroad supplies, I will state that the name of the company undertaking this work is the Cienfuegos, Palmira and Cruces Electric & Power Company, with headquarters at Cienfuegos."

The Repulsion Type of Alternating Current Motor.

In a paper presented last week before the American Institute of Electrical Engineers, entitled "The Alternating-Current Railway Motor," Mr. C. P. Steinmetz, after referring to the early work of the late Rudolph Eickemeyer with the single-phase alternating-current motor, gave in extenso the theory of the Thomson repulsion type of motor.

In introducing the paper Mr. Steinmetz said that for electric railway work a motor is required which maintains a high value of efficiency over a wide range of speed. That is, the torque per ampere input at constant impressed voltage must increase with decrease of speed, the speed increasing with decrease of load.

In electric motors, torque is produced by the action of a magnetic field upon currents flowing in an armature movable with regard to the field. If then the field is constantly excited—shunt motor on constant potential—the torque is approximately proportional to the current, the speed approximately constant at all loads. If the field is excited by the main current of the motor—series motor on constant potential—the field strength and thereby the torque per ampere varies approximately proportional to the current, and thereby the load, the whole torque approximately to the current, and thereby load, the whole torque approximately proportional to the square of the current and the speed inversely proportional to the current, leaving saturation out of consideration. That is, the motor has the characteristic specified above for a railway motor.

Since the direction of rotation of the direct-current motor is independent of the direction of the impressed e.m.f., with laminated field the direct-current motor can be operated with alternating-currents. By the use of alternating currents it becomes possible to transfer current from circuit to circuit by induction, and instead of passing the main-line current through the armature of the alternating-current motor, the armature circuit can be closed upon itself and the current induced therein as transformer secondary by a stationary primary coil in the main circuit surrounding the armature.

The condition of operation of the direct-current motor type on alternating current is, however, that the current in field and armature reverses simultaneously. This is by necessity the case in the series motor. In the shunt motor, however, the armature current as energy current should be in phase with the impressed e.m.f., while the field current as magnetizing current lags nearly 90°. To bring it back into phase, Stanley tried condensers in series in the field circuit, but failed, due to the impossibility of neutralizing the self-induction of the field which varies with the commutation and the frequency, by the negative self-induction of the condensers, which varies with the frequency in the opposite direction. The solution of the problem has been found in the use of polyphase systems, by utilizing for the field excitation the e.m.f. in quadrature with the armature currents acted upon by the field magnetism. Mr. Steinmetz says that as he has shown elsewhere, the polyphase induction motor can be considered as a development of the direct-current shunt motor for alternating-current circuits, and indeed has all the shunt motor characteristics regarding speed, torque, etc. As a railway motor the induction motor has therefore not been exploited, although it has been strongly recommended in those very few cases where it appeared good engineering. Experimental work with polyphase induction motor railways has been carried on continuously since 1893.

While in the early days of alternating-current motor development, all other engineers were industriously developing the type with shunt motor characteristic, Rudolph Eickemeyer, of Yonkers, alone was far-sighted enough to realize the absolute necessity of the series motor characteristic for railway work and undertake the development of the single-phase alternating-current series motor. Mr. Steinmetz added that he had the good fortune at that time to be associated with Mr. Eickemeyer.

As was pointed out by Kapp, in 1888, the power factor of the alternating-current series motor is inherently low, since the same magnetic flux which induces, proportional to the frequency of rotation, the e.m.f. of useful work in the armature conductors, induces in the field coils an e.m.f. of self-induction, proportional to the frequency of alternation, thereby giving the armature the same number of turns as the field (which is more than permissible in good practice, since good practice requires weak armature and strong field). Even at synchronous speed the e. m. f. of rotation of the armature would still only be equal to the e. m. f. of self-induction of the field; and the power-factor, allowing for an additional self-induction of the armature, would be below 70 per cent. This probably deterred the other engineers from considering the alternating-current series motor.

Eickemeyer solved the difficulty by designing the armature with a number of turns several times greater than the field (25 to 7 in the first motor built) and neutralizing the armature self-induction and reaction by a stationary secondary circuit surrounding the armature at right angles electrically to the field circuit (the "cross-coil," as he called it), and either short-circuited upon itself or energized by the main current in opposite direction to the current in the armature.

In January, 1891, Mr. Steinmetz tested the first motor of this type, a bipolar motor with the following constants:

Field: Two coils of 14 turns No. 10 B. S. wire, connected in parallel. Armature: 24 coils of four turns each of No. 12 B. S. wire. Secondary circuit: Two coils of 18 turns each of No. 10 B. S. wire connected in parallel.

At 100 cycles and 150 volts impressed e.m.f., this motor gave

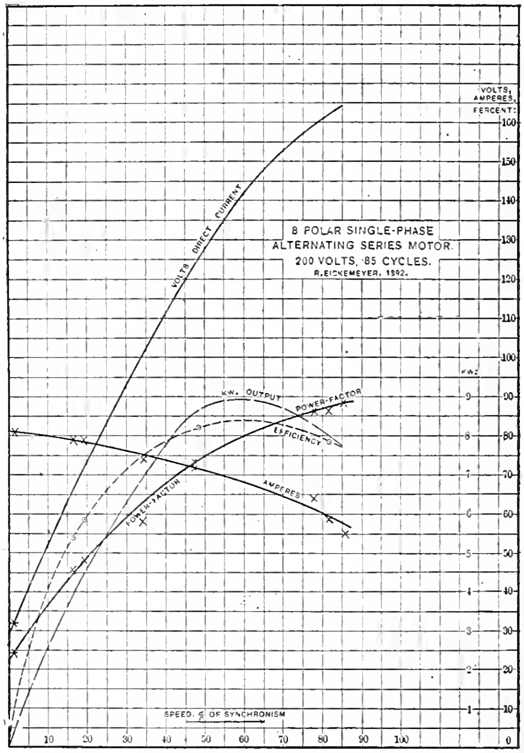

FIG. 1.—TEST CURVES OF EICKEMEYER MOTOR.

a three-fourths synchronous speed, and its starting current at 150 volts and 70 amperes.

Current: 45 amperes. I^2R: 400 watts. Hysteresis and eddy currents: 900 watts. Total output, including friction: 4,000 watts.

Hence the efficiency was 75.5 per cent., and the power factor, 79 per cent.

As a bipolar motor with the very high frequency then used, the speed, 4,500 revolutions at three-fourth synchronism, was undesirably high, so immediately an 8-polar motor was built. In this, solid copper rings were used as secondary circuits surrounding the armature and neutralizing its self-induction, with an effective copper section more than four times that of the armature conductors. The ratio of armature series turns to field series turns was about 4. This motor was tested in 1892. The record of tests is given in Fig. 1, the observed values being marked on the curves. For comparison on this sheet is also given the direct-current voltage required to operate this motor at the same speed and current.

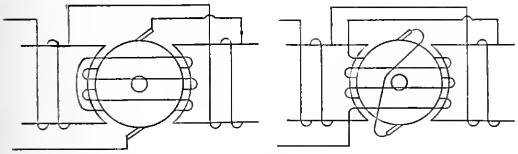
As will be seen, when approaching synchronous speed, the power-factor is nearly 90 per cent. The commutation was fair at 85 cycles, the highest frequency at which the factory engine was able to drive the alternator, and attain at 33 cycles.

A number of railway motors of this type were designed. The great difficulty, however, was that during these early days 125 to 133 cycles was the standard frequency in this country, 60 cycles hardly considered, and 25 cycles not yet proposed.

The efficiency of this alternating-current series motor is slightly lower than that of the same motor on direct-current circuit, due: (1) To the hysteresis loss in the field. (2) The hysteresis loss in the armature core, which is of full frequency up to synchronous and of still higher frequency, the frequency of rotation, beyond synchronism. (3) The I^2R loss in the short-circuited secondary conductors surrounding the armature.

As will be seen, to make the alternating-current series motor practicable, the transformer feature must be introduced, by having its armature as primary circuit closely surrounded by a short-circuited secondary circuit, as shown diagrammatically in Fig. 2.

Instead of closing the stationary circuit upon itself as secondary



FIGS. 2 AND 3.—DIAGRAMS OF ALTERNATING-CURRENT SERIES MOTOR.

circuit and feeding the main current into the rotating armature as primary circuit, mechanically the same results would obviously be obtained by using the stationary circuit as primary energized by the main current and closing the armature upon itself as secondary by short circuiting the brushes and thereby keeping the main current and the line potential away from the armature, as shown diagrammatically in Fig. 3. This introduces the great advantage of reversing the sign of the uncompensated part of the armature self-induction, so that it is subtractive, which results in an essential improvement of the power-factor, especially at low speed.

This is shown in Fig. 4, where with the speed as abscissas, in per cent. of synchronism, are plotted the power factor of the Eicke-

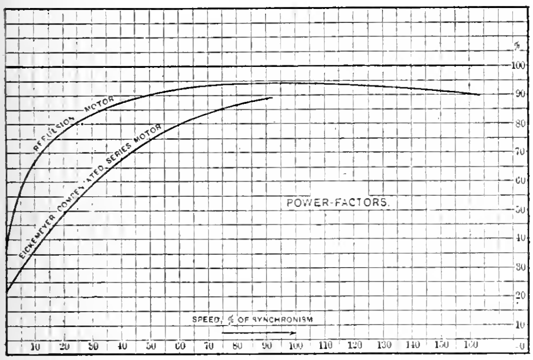


FIG. 4.—POWER FACTOR CURVES.

meyer compensated series motor of Fig. 1, of ratio armature to field = 4, and the power-factor of one of the first railway repulsion motors, of ratio armature to field = 3.5.

The compensation of the armature self-induction in Fig. 3 is based on the feature of the transformer that primary and secondary current are in opposition to each other. The secondary current of the transformer, however, lags slightly less than 180° behind the primary current; that is, considering it in the reverse direction, is a leading current with regard to the primary current. The current in the armature in Fig. 3, is, therefore, a leading current with respect to the line current, and so not only does not add an additional lag but reduces the lag caused by the self-induction of the field-exciting coil.

This motor then consists of a short-circuited armature surrounded by two coils at right angles with each other and connected in series, as illustrated in Fig. 5; the one A_2, parallel with the effective armature circuit, acting as primary of a transformer to induce the secondary armature current; the other, A_1, the field exciting coil. The ratio of turns of the coils, n_2 to n_1, is the ratio of ef-

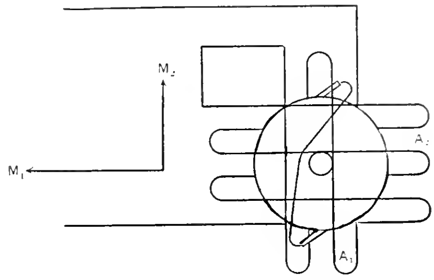

FIG. 5.—DIAGRAM OF EICKEMEYER MOTOR.

fective armature series turns to field turns, as discussed before. Obviously, these two coils can be replaced by one coil at an angle with the position of brushes as shown in Fig. 6, and the cotangent of the angle of the axis of this coil with the position of the brushes is above ratio; that is, the smaller this angle the greater is the ratio of armature to field turns; that is, the better the power-factor of the

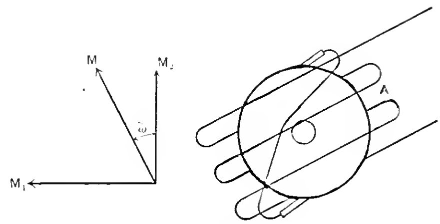

FIG. 6.—DIAGRAM OF THOMSON REPULSION MOTOR.

motor. This motor is Professor Elihu Thomson's repulsion motor.

In the armature an e.m.f. is induced by the alternation of the magnetic field, M_2, of coil A_2, proportional to M_2 and to the impressed frequency and in quadrature with M_2, and an e.m.f. is induced by the rotation through the magnetic flux M_1 of coil A_1, proportional to M_1 and to the frequency of rotation and in phase with M_1. These two e.m.f's must be equal and opposite, since the armature is short circuited (neglecting the resistance and self-inductive reactance of the armature) and at synchronism. Therefore M_1 and M_2 are equal and in quadrature with each other; that is, in the armature of the motor, Fig. 5, and therefore of the repulsion motor, Fig. 6. At synchornism a uniform rotating field exists and the hysteresis loss in the armature core is therefore zero at synchronism and at other speeds proportional to the difference between speed and synchronism; that is, to the slip, just as in the polyphase induction motor, while in the motor, Fig. 2, the hysteresis loss in the armature core is proportional to the impressed frequency or the frequency of rotation, whichever is the higher frequency. The hysteresis loss of the repulsion motor is, therefore, lower than that of the same motor as compensated series motor.

In Fig. 6 the magnetic flux in line with the brushes, which does not induce e.m.f. by rotation but only by alternation, is denoted by M_2; the magnetic flux in quadrature with the brushes which induces e.m.f. in the armature by its rotation but not by the alternation of the flux, by M_1; and the magnetic flux in the axis of the primary coil A, which is much nearer to M_2 than to M_1, since a good power factor requires a small angle ω, by M. Mr. Steinmetz then shows mathematically that M_1 and M_2 are in quatrature in phase and the ratio of their intensity is inversely proportional to the ratio of speed to synchronism. Fig. 7 shows the two quadrature components, M and M_2 of the magnetic field of the repulsion motor for $\omega = 16°$ and $M = 1.0$.

That is, in the repulsion motor an elliptically rotating field exists which becomes circular; in other words, a uniformly rotating field, at synchronism. Below synchronism the component, M_1, which induces e.m.f. by the rotation of the armature is greater than M_2, the more the lower the speed. The flux M interlinked with the primary coil is, however, nearer to M_2 and therefore below synchronism, especially at low speeds. The magnetic flux which induces e.m.f. by the rotation of the armature and so represents the useful work, is greater than the magnetic flux which interlinks with the primary coil and so gives the lag of the primary current. This accounts for the high power-factor of the repulsion motor at low speeds.

The paper then proceeds to give a theoretical investigation of the repulsion motor considered as a transformer, the secondary of which is standing at a constant angle ω with regard to the primary, so that motion results from the repulsive thrust existing between primary and secondary.

One of the deductions is that, unlike the plain series motor, which can never return power into the line, the repulsion motor when reversed becomes a generator, consumes mechanical power as brake and returns electric power into the line, even at low speeds. Experiment verifies this feature.

In discussing the mathematical theory developed, it is stated that

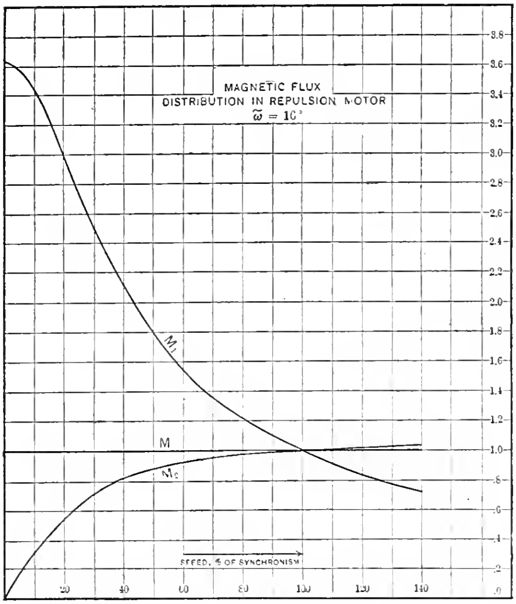

FIG. 7.—MAGNETIC DISTRIBUTION IN REPULSION MOTOR.

the primary exciting, primary self-inductive and secondary self-inductive impedances have been assumed as constant. While this is approximately the case in the ordinary induction motor, it is not the case with the repulsion motor which works over a wide range of magnetic flux densities.

With increasing load and thereby increasing current and decreasing speed, magnetic saturation is approached and causes a decrease of the impedances, which has to be taken into consideration in predetermining the characteristic curves of such a motor. Furthermore the different component magnetic fluxes are affected differently by saturation. The flux, M, interlinked with the primary coil is approximately constant and therefore affected by saturation only indirectly, while the flux, M_1, at right angles to the line of polarization of the secondary coil is approximately proportional to the load and so reaches saturation at high loads, and the impedances become thereby different in the different directions of the magnetic structure.

The m.m.f's in the investigation were treated as vector quantities, independent of their distribution around the periphery of the armature. This distribution, however, is different with the different m.m.f's. The m.m.f. causing the effective flux, M_1, is due to a zone of the primary winding within the angle $\pm\ \omega$ from the axis of the secondary coil, hence nearly a concentrated winding, which gives a flat-topped flux distribution, while the flux, M_2, in the direction of the axis of the secondary coil is that of a distributed winding or peaked. For the same m.m.f the effective flux, M_1, is, therefore, greater than the effective M_2. Taking this into consideration, gives the motor somewhat better characteristics than calculated above. Owing to the different wave shapes of the fluxes, M_1 and M_2, they are affected differently by saturation. The flat-topped flux M_1 reaches saturation at a much higher value, but then over the whole range, while the peaked flux M_2 shows the effect of saturation at a lower value but then gradually, by a rounding off of the peak. In the repulsion motor it is therefore not sufficient merely to consider the resultant m.m.fs. as vectors but their distribution in the air-gap and the effect of saturation must be taken into consideration in the calculation and design of the motor. Mr. Steinmetz adds that an exhaustive investigation of this point has been made by his assistant, Mr. M. Milch, and may be communicated at a later date.

The secondary circuit of the motor has been considered as the seat of two e.m.fs. induced respectively by the rotation through flux M_1 and by the alternation of flux M_2. These e.m.fs., however, have no separate existence. At synchronism, for instance, the magnetic field is an approximately uniformly rotating field and, therefore, no e.m.f. is induced in the armature conductors except that required to overcome the resistance. The secondary frequency varies with the load and thereby the secondary self-inductive reactance which we assumed as constant in the preceding discussion. Mr. Steinmetz says this is best taken into consideration by a theory developed by his former assistant. Mr. S. Sugiyama, of Japan. The primary impressed alternating m.m.f. of the current I is resolved into two component m.m.fs. of half intensity, revolving synchronously in opposite directions. If now $a =$ the ratio of speed to synchronism, the two oppositely revolving components of I revolve with regard to the secondary system with the speeds $(1 - a)$ and $(1 + a)$ respectively. The same consideration applies to the secondary m.m.f. I_1, and in the secondary system we then have induction at two frequencies, $1 - a$ and $1 + a$, of which the former becomes zero at synchronism. That is, at synchronism the secondary current in the armature conductors is of double frequency, similar as in the ordinary single-phase induction motor. At other speeds it is the superposition of two currents of the frequencies $1 - a$ and $1 + a$, respectively. This theory more closely allies the repulsion motor with the ordinary induction motor. Using the same values of secondary impedance, Z_1 for both components, obviously leads to identically the same equations as given in the preceding.

The complete investigation of the repulsion motor must also take into consideration the current flowing in the armature coil during the moment where the coil is short circuited by the brushes passing from commutator segment to segment. The m.m.f. of this short-circuit current of commutation is at right angles to the axis of secondary polarization of current I_1, hence has the angle of brush-shaft — $(90 - \omega)$. A corrective term must, therefore, be applied, taking this phenomenon into consideration, essentially of the character of a repulsion machine with negative or generator brush-angle of $(90 - \omega$ and very high effective secondary resistance. This term is very small or negligible at speeds up to a point somewhat beyond synchronism but becomes noticeable at speeds considerably above synchronism, due to the decrease of the main current at these speeds. The main effect of this phenomenon is that the power-factor of the motor instead of increasing indefinitely with the speed up to 100 per cent at some very high speed (and then decreasing again slightly with leading current), reaches a maximum somewhere between 90 and 97 per cent., according to the constants of the motor, and then very slightly decreases with increasing speed, as is shown in the curve of the power factor of a repulsion motor in Fig. 2.

Cables as Heartstrings.

At the dinner of the Pilgrims' Society, January 29, the London and New York contingents banquetted on the same night; here at Delmonico's, and in London at the Carlton. The Commercial Cable wire was run into both rooms and friendly messages freely exchanged. In London, the unique feature of the evening consisted in the installation by the cable company of two old grandfather's clocks, one showing English and the other American time which enabled Mr. Choate, Lord Salisbury and the others to keep an eye on the progress of the New York banquet. The usual cable company's clock, with a red hand showing American time, was placed between the two clocks. The tables were also decked with telegraph wires and miniature poles.

Women in the German Telegraph-Telephone Service.

In a recent report on the subject of the employment of women in the telegraph and telephone service in Germany, Mr. J. F. Monaghan, United States Consul at Chemnitz, says:

"While women were employed in the postal and telegraphic service of France and England as early as 1820 and 1830, Germany did not make a trial of feminine service until 1874. The main circumstance that led to the employment of women at that time was a scarcity of available men. When later the administrations of the postal and telegraphic services were combined under one head, a general discharge of the women who had obtained positions in the service followed, largely, so it is reported, because Postmaster-General Stephan, who wielded a determining influence at the time, was irreconcilable in his opposition to the employment of women in the postal and telegraphic service. Hence, all women engaged in the telegraphic service were removed, and only a comparatively small number of those employed in the postal service reluctantly retained as a further experiment. Three years later, in 1876, these also were separated from the service of the Empire.

"The successor of Stephan, Postmaster-General Podbielski, was favorably disposed toward the employment of women. He laid considerable weight upon the successful experience with women in foreign countries, especially in the United States. Through his support and influence women were again introduced into the postal service, though only in limited numbers and purely for the purpose of further trial. The result was quite as satisfactory as had been expected, and since then the number of women in the German postal, telegraphic and telephonic service has been rapidly increasing, until to-day they comprise an invaluable and indispensable part of the same.

"In all post offices of the third class women assistants are appointed by the postmasters of the place, under strict limitations, however, of government regulations respecting age, character and education. Such assistants must be of sound health, certified to by a government medical examiner. They must be entirely free from all deformities, of stainless character, from 18 to 30 years of age, and must possess a good common school education. The highest salary that may be paid to such assistants at third-class post offices is 500 marks ($119) per year. In post offices of the first-class and at railroad post offices women may be engaged for service as typewriters or similar duties only. All women assistants have the character of government officials (Beamteneigenschaft), which means that on their withdrawal from the service after faithful, competent work during a prescribed number of years they have a claim to a pension (Ruhegehalt), under the law of the Empire, if their circumstances are adjudged such as to require it. Instead of being qualified to occupy only a certain class of specified positions, as was found to be the case in the German postal service, women are privileged to take any positions whatever in the telegraphic service, subject at all times to the above-enumerated regulations respecting age, character and education. They have a similar claim to a pension as those engaged in the postal service and in all respects are similarly employed, privileged and discharged.

"At the present time 4,000 women are employed in the telephone service of the German Empire. In Berlin alone 1,000 women are engaged. These positions are so popular and the number of applications is so large that the number of accepted and qualified women whose names have been registered in the order in which they were considered is so large as to supply occupants for any possible vacancies that may result in the course of the next few years. Only physically strong girls are admitted to the service. They must possess a good character and be of respectable families. They must be between 18 and 30 years of age and either unmarried girls or widows without children. Every applicant must possess an education equivalent to graduation from an elementary school (Elementarschule). In making the application for a position it is necessary to produce a birth certificate, school certificate, certificate of conduct (Leumundszeugnis), in which are registered all praise or dissatisfaction expressed by previous employers of the person in question, and a brief biography. The latter must have been written and constructed solely by the applicant. The written consent of the father or guardian is also necessary. Some time after the application, accompanied by all the required papers, has been filed notice is sent to the applicant to appear for an examination, which embraces ordinary questions of arithmetic, German and geography.

"After successfully passing the examination the applicant is sent to an official medical examiner, who must certify as to her physical and nervous soundness, and especially as to the condition of her lungs and nerves.

"Having successfully acquitted herself in all the foregoing tests, the applicant is now ready to begin a period of practical preparation. This work as an apprentice covers from three to four weeks, and during the time the learner receives no salary. Having satisfactorily completed her period of practical study, the applicant is ready to enter upon a regularly paid position. Since, as was already stated, the number of applicants is always extremely large, a number of months or even a year or two may pass before a vacancy occurs. A position being open, the applicant cannot enter upon the same if she has in any way, in the meantime, spoiled her record or failed to preserve a stainless character. She must also, at the time of her employment, be living with her parents, or in some other respectable place free from all question.

"The daily hours of employment vary from six to eight; sometimes Sunday work is required. The employee must, immediately after being engaged, begin her contributions to the sick fund (Krankenkasse beitreten), and in case she succumbs to sickness or injury she continues to draw three-fourths of her regular salary and receives free medical treatment. Her pay to begin with is 2.25 marks (53.5 cents) per day. After two years of satisfactory service this is raised to 2.50 marks (59.5 cents) per day. After two additional years—that is, after having been four years in the service—her pay is raised to 3 marks (71.4 cents). If, after service for several more years, the girl has shown herself capable and unusually diligent, she may be appointed as supervisor (Aufsichtsdame), with an annual increase in pay of 100 marks ($23.80).

"After ten years of faithful service another advantage is added in the form of appointment with full claim to a pension (Anstellung mit Pensionsberechtigung). After being thus engaged, her salary amounts to 1,100 marks ($261.80). This salary is then increased every three years by the amount of 100 marks ($23.80) until it amounts to 1,500 marks ($357). This is the highest salary that a woman can draw in the German telephonic service. It is sufficient to insure a comfortable existence to the employee, though to an American the amount may seem somewhat small, even for an exceedingly plain living. It must be remembered that the German women living in Germany who belong to this class of wage earners can live with considerably less expense and with much greater comfort than would be possible in the United States.

"In England the salaries of positions of this kind are much better paid. Girls are admitted to the service at 15 years of age. During the first years, while they are 'girl clerks,' they receive from 800 to 900 marks ($190.40 to $214.20). When they receive a permanent position as 'women clerks' their salary is increased to 1,100 to 1,200 marks ($261.80 to $285.60). After twelve years of faithful service they receive the considerable salary of 2,400 to 2,500 marks ($571.20 to $595). The best women are even appointed to positions as chief supervisors or assistants in first-class offices, with a salary of 10,000 marks ($2,380)."

A Canadian Electrothermic Commission.

The commission recently appointed by the Canadian Government to investigate all existing electrothermic processes of manufacturing iron and steel in Europe, sailed from New York January 23 on the Cunard Line steamer *Lucania* for Liverpool. The commission is made up of Dr. Eugene Haanel, superintendent of mines in Canada; Mr. C. E. Brown, electrical engineer; Mr. Nystrom, draughtsman; Mr. Thomas Cota, secretary, and a steel expert and photographer who will join the party in England.

The commission will visit Sweden, France and Italy, and it is probable that some four months or more will be used in carrying on the work of investigation and research. For years the rich iron mines of Canada have remained dormant with abundance of water power available on all sides. But it is now believed by the Minister of the Interior in Canada, and by financiers, that the work of this commission will pave the way for great industrial prosperity in the Dominion.

Nowhere in America has the electric furnace been commercially applied to the manufacture of iron and steel, but in Europe much has been done in this direction. There the possibilities of the furnace in the metallurgy of iron and steel are well recognized, and much good work has been done.

New Telephone Patents.

IMPROVED LINE APPARATUS.

There was a time when all details of telephone pole line construction were entirely in the hands of the line foreman. There was little apparatus especially designed to meet his needs and he, therefore, had to makeshift with the various materials at hand in overcoming the difficulties, and in solving the problems met. This is now, however, all changed, as the requirements for poles, arms, guys and wires are well understood and the assembling of them into a line is prescribed in comprehensive specifications. These latter, however, are continually undergoing a revision to keep pace with the inventors, who are at frequent intervals developing improved accessories.

We have at hand for present consideration four patents covering line accessories, which have been lately invented. One of these patents describes a new method of "tying-in" line wires. The preferred scheme employs a tie wire, the middle portion of which is flattened out into a ribbon. This ribbon portion is wrapped in a close spiral around the wire to be secured, at the joint where the line wire passes the insulator. The two ends of the tie wire are then passed around the insulator and secured by twisting them together on the side opposite the line wire. This invention is the work of Alexander Kline, of Jersey City, N. J.

Another patent concerns an apparatus for anchoring guys. For many years the only anchor known was a rock, or log buried in the earth. The labor of digging is a matter of such trouble and expense that a great deal of ingenuity has been displayed in developing an anchor which can be driven, and a number of such are now upon the market. The present patent describes an anchor of this type comprising a shank with pivoted wing pieces, which assume a position at right angles to the shank in case any attempt is made to pull it up. The only improvement claimed is a shaping of the butts of these wings so as to concentrate all stresses upon their pivots. W. G. Beach, of Grandlake, Kan., is the patentee of this anchor.

Two cable suspension clips form the subjects of the remaining line material patents. These are both the work of one inventor, O. C. Hoffmann, of Chicago. Both follow the general design of the most successful clips of to-day, consisting of a strip of sheet zinc to surround the cable and a suspension hook of wire so formed that by intertwining the end of the zinc strip with it the whole forms a secure fastening. The exact method of using the clips will be better understood from a glance at Fig. 1 than from any description. The clip in the lower part of the figure is shown just ready to hook over the messenger strand.

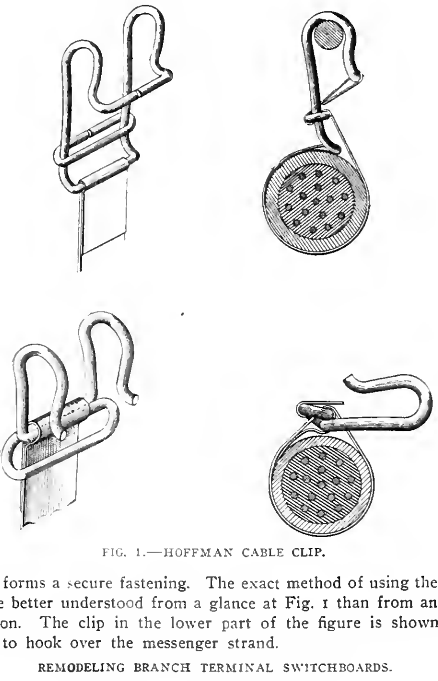

FIG. 1.—HOFFMAN CABLE CLIP.

REMODELING BRANCH TERMINAL SWITCHBOARDS.

Before the advent of the common battery switchboard the most approved form of board for large central offices was the multiple bridging or branch terminal board. Many of these are doubtless in use to-day and in a state of preservation such that the improvement in service with the central battery board does not seem of sufficient weight to warrant their rejection. Several suggestions as to methods of remodeling such switchboards so that much of their apparatus and wiring might be retained, and yet providing a central battery service, have been put forward as a solution of the difficulty; but heretofore a practical trial has proved all such suggestions to have been faulty in conception. A new idea in this direction, which appears encouraging, is disclosed in a patent issued to M. C. Rorty, of Dedham, Mass., and assigned to the American Telegraph & Telephone Company. The remodeled system contemplates the use of the drops and jacks, both answering and multiple, together with practically all of the magneto system wiring associated with them—a great saving. The connecting cord circuits must, however, be reversed, although the keys and plugs are suitable for reuse. In Fig. 2 is shown the remodeled system in diagram, in which will be recognized at once the standard Bell common battery subscriber's station set, and the standard bridging line circuit. The only changes in this latter are the insertion of a battery and retardation coil in the drop circuit. The battery, of course, causes the drop to fall as soon as the line circuit is closed by the release of the subscriber's hook switch. The retardation coil serves to balance inductively the effect of the earthed line drop coil, which, as there is no cut-off device, remains legged to ground at all times. The cord circuit is novel only in the provision of a relay in the battery supply to the repeating coils, which, through its contacts, controls the supervisory lamps, so that these may glow only when the plugs are in the jacks. The busy test is quite similar to that of the standard bridging switchboard.

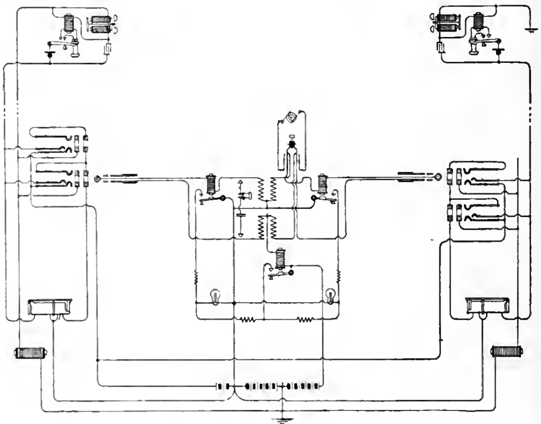

FIG. 2.—RORTY SWITCH AND SIGNAL SYSTEM.

NEW APPARATUS.

An improvement in magneto bells has been made by A. M. Knudson, which consists essentially in providing a base plate upon one side of which the gong posts are secured and from the side of which the ringer frame and magnets project. This arrangement makes the bell complete in itself, and it may be removed from its containing box as a whole. The base plate serves as an escutcheon for the opening in the box through which the bell is to be inserted, and thus the whole gives a neat appearance. The Kellogg Switchboard & Supply Company have obtained Mr. Knudsen's patent by assignment.

A rather unusual piece of apparatus is a plug with an automatic switching device contained within its shank, which has been designed and patented by F. D. Pearne, of Chicago. It is evidently Mr. Pearne's idea to use this switching device in the plug to control the supervisory lamp circuit of modern switchboards and to save thereby one of the relays of the cord circuit in two-wire switchboards. The automatic switch consists of mercury traveling in a glass tube carrying sealed-in terminals. It is doubtful if any material gain will result from its use, in the first place because the connecting cords must contain conductors to lead to and from it, and secondly because of the untrustworthy characteristics of mercury switches in continual use.

Fig. 3 shows a new form of dust-proof relay. This, it will be noted, follows in many details some of its predecessors, the chief novelty lying in the use of an intermediate lever member between the contact springs and the armature. It is impossible to predict just of

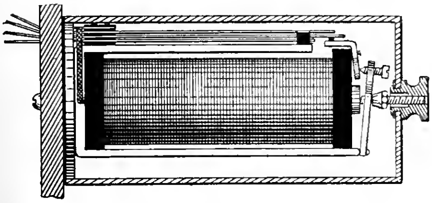

FIG. 3.—DOWNS RELAY.

what advantage such an arrangement will prove, but a multiplication of parts always raises some doubt. The patent for this relay has been granted to J. P. Downs, of Cleveland, Ohio, and has been assigned to the North Electric Company.

SIGNALING SYSTEM.

Everyone has observed the appreciable interval of time required for the filament of an incandescent lamp to cool after the current is shut off, and it is only reasonable to suppose that there must be some corresponding though shorter interval ordinarily required for the filament to attain its brilliancy. Mr. H. P. Claussen, of Chicago, feels that this retarded lighting may result in a failure of the signal of an incandescent switchboard signal lamp, in case its controlling circuit be rapidly closed and opened by a rapid vibration of the switchhook or other circuit-closing device. He, consequently, in endeavoring to overcome any such difficulty, has arranged and patented a signal lamp circuit such that a large rush of current far above the normal current of the lamp flows in the first moment of the closing of its circuit. This sudden abnormal current lights the lamp at once, after which the current is reduced automatically to normal by a relay wired in the lamp circuit and controlling a shunt about the lamp. The American Electric Telephone Company has been assigned the patent for this method of causing lamps to glow.

AUTOMATIC SWITCHING MECHANISM FOR PRIVATE LINES.

Two patents have been issued to U. S. Jackson, of Boston, describing an automatic switching mechanism for use on party private lines, which operate without any central office. Each station is provided with a spring motor, which becomes locked at such times as the line is in use. This precludes any interruption to conversation between two stations from the selective currents of other stations, and as the talking circuit of each set is also controlled by existing conversations, no interruption or listening can be done. The selection of desired stations is performed by impulse currents from a circuit-breaker driven by the spring motor and controlled by the calling party. These currents cause the operation through an electromagnet, and a ratchet and pawl revolve the selecting commutators at all stations, arresting their motion in position for the signaling of the desired station only. Such an arrangement, unmodified, of course, permits one station to hold up the whole line. The necessary modification to prevent this has, however, been provided in the form of a switch upon the receiver of the calling station. This switch must be depressed at all times during conversation or the line will be automatically returned to the normal condition, releasing all stations.

COMBINED ALARM AND TELEPHONE SYSTEM FOR POLICE SERVICE.

In many cities the patrol boxes for the use of the police have for a number of years been provided with alarm signals and in others with telephone instruments. It is now proposed to combine these systems in the same boxes, using the same wires to the central station. This new system provides the usual alarm apparatus to send in automatically the number of the box from which an office is reporting. It provides an answer-back signal signifying the receipt of the telegraphic report, this signal being a hum on the line produced by a buzzer at the central, and to be noted by the office by the use of the telephone receiver; and lastly it provides an alarm signal to notify the officer that he is to use the telephone to receive orders or other information. W. E. Decrow is the patentee, he having assigned his patents to the Gamewell Fire Alarm Telegraph Company.

Wilkinsburg Electric Club.

Organized in the spring of 1902, the Electric Club, of Wilkinsburg, Pa., has at present a membership of more than 500, handsome quarters and a most efficient organization for carrying out the technical purposes which form no small part of the object of the body. Evidently much thought has been given to the organization of the club in order to properly balance its several features, and particularly to render it of the greatest use in every possible direction to its members, who are mostly employees of the Westinghouse Electric & Manufacturing Company. The accompanying illustrations give an idea of the manner in which the club is housed. Its main rooms occupy the whole of a floor of a large building in Wilkinsburg, Pa., with additional space on another floor for games and smoking rooms. The illustrations show the assembly room, which has a seating capacity of about 300 and is used for general and technical lectures, meetings

FIG. 1.—ASSEMBLY ROOM.

of the local section of the A. I. E. E., weekly meetings of the East Pittsburg Drawing Class, and for Saturday evening entertainments and dances. Another illustration shows the reading room, and a third one of the three class rooms.

The organization is very thorough, consisting of a board of direc-

FIG. 2.—READING ROOM.

tors and seven committees, namely, house, library, excursion and research committees, and committees on lectures, section and class work. Every Saturday evening entertainments are held in the club room under the auspices of the ladies' committee. Several times a month technical papers are read by members of the Westinghouse staff and other authorities on the subjects treated. During the month of last February, for example, Prof. W. S. Franklin read a paper on the "Choice of Signs in Polyphase Systems and Ratings of Polyphase Transformers"; Mr. L. M. Aspinwall, of the Westinghouse Company, one on "Systems of Control for Electric Street Railway Work"; Mr. Paul M. Lincoln a paper entitled "Some Features of

Niagara Falls Power Work"; Mr. W. K. Dunlap one on "Some Problems in Construction Work," and Mr. W. J. Beck a paper on the "Testing of Iron and Steel for Electrical Purposes." Classes have been organized for the benefit of the members of the club who have not received a technical education, to enable them to study elementary electrical theory as applied to the apparatus manufactured by the Westinghouse Company. At present there are two classes, one meeting every Tuesday and the other every Friday evening. There are also ten sections which meet to discuss apparatus, shop methods and technical subjects. These sections cover the subjects of direct current, alternating current and railway work, transformers, testing,

FIG. 3.—ONE OF THE CLASS ROOMS.

detail apparatus, road engineering and switchboard, alternating-current work and transformers, having each two sections.

An idea of the activity of the club may be gathered from the following calendar for the spring of 1903:

On Mondays there was a general or technical lecture; on Tuesday evenings a meeting of Class A and Sections 1, 4 and 8; on Wednesday evenings, Drawing Class lectures and meetings of Sections 2, 3 and 5; on Thursdays a general or technical lecture; on Fridays, meetings of Class B and Sections 3, 6 and 7, and on Saturday evenings social meetings with an excursion the third Saturday of each month. The local section of the American Institute of Electrical Engineers meets each month at the club room, all members of the club having the privilege of attending. In the evening drawing classes there are about 100 students, divided into four sections, instruction being given on Mondays, Tuesdays, Thursdays and Fridays. We gather the above information from a handsome brochure issued by the club, which contains illustrations of the club quarters, and information in detail as to the personnel and work of the body.

Recent Electrochemical Developments.

ELECTRIC FURNACES.

In a patent granted on January 26, Mr. Henri Harmet, of St. Etienne, France, who is well known from his work in the electrometallurgy of iron and steel, describes a form of electric blast furnace which contains a lower fusion zone and an upper reduction zone. Electrodes extend into the fusion zone from the outside. The ore, with an excess of reducing carbon, is charged into the top of the furnace and current is supplied through the electrodes so as to form a local fusion zone. There is at this place an excess of heat which would be wasted, if it would pass downward with the molten metal. To prevent this, the inventor proposes to take away the gas escaping at the top of the furnace and carry it downwards with the aid of a fan or blower into the fusion zone, whence it is pressed upwards. The heat of the fusion zone is thus diffused upwards, and the gas when coming into contact with the incandescent coke adjacent to the fusion zone is converted into carbon monoxide, which, when passing through the charge, creates a reduction zone above the fusion zone. The reduction of the charge thus precedes the fusion, and the operation is continuous.

A patent granted to Mr. R. C. Contardo, of Sèvres, France, relates to the design of an electric furnace, the hearth of which has a curved surface, with electrodes above the same. The arch above the hearth consists of two downwardly inclined surfaces, while parallel with the same there are side walls so as to form two inclined flues through which the ore is passed downwards. The heat radiated from the arcs upwards is thus utilized to preheat the charge passing through the flues. The gases developed during the reduction are led away, and the inventor proposes to utilize their caloric effect in gas engines driving generators which are to furnish current for the operation of the furnace.

BATTERY INVENTION.

A patent granted to Messrs. C. P. Elieson and V. de Bobinsky, of Paris, France, relates to the construction of a storage battery plate with a central conducting core of lead, and strips of this lead alternately flat and corrugated, attached at one end to each side of the core and free at their other end. A strengthening frame, comprising upper and lower cross pieces of insulating material and india rubber ligatures, bind the whole together, but allow a free lateral expansion of the thin lead strips.

Radium in Medicinal Springs.

Note was made in these columns recently of the fact that radium in appreciable quantities has been found in the famous springs at Bath, and it is stated on high scientific authority that there is little doubt there are large quantities of it deep down in the earth. Further details are to hand from England. For some time Prof. Dewar has, at the expense of the Royal Society, collected the gases that rise in the largest and best-known of the Bath springs—the King's Bath—and the result of his analysis revealed the fact that the rare element helium existed in the Bath waters.

The existence of helium led to the belief that something more of scientific interest might be found in the deposits in the tanks and pipes at the three springs, inasmuch as Sir William Ramsay recently discovered that helium is slowly evolved from radium. A quantity of deposit from the New Royal Spring was obtained, and was sent to the Hon. R. J. Strutt, son of Lord Rayleigh, who made a careful investigation of the material submitted to him. The result of his investigation he has just communicated in a letter to the Bath authorities.

"I have found," says Mr. Strutt, "that the deposit contains radium in appreciable quantities, though I am sorry to say not enough to pay for extraction. I think there can be little doubt that the helium of Bath owes its origin to large quantities of radium at a great depth below the earth's surface. A little of this radium is carried up by the rush of hot water, and it is found in the deposit. My experiments promise further interesting developments."

This letter was read at a meeting of the Bath City Council by Mr. T. Sturge Cotterell, who added that Mr. Strutt had since written that by "appreciable quantities" he meant quantities such that its presence "may quite easily be detected." But the percentage found was less than in the ore from which radium is at present obtained. About ninety-eight gases are given off by the Bath waters, and Prof. Dewar examined samples of them all. The deposit which Mr. Strutt examined is one of countless peculiar features of the Bath waters. It settles on walls and the bottoms of tanks and corrodes pipes, being like mud of a rich orange color. When dry it is orange-colored powder, but duller in hue and very fine in substance. Settling on stone or projections, it hardens and assumes the appearance of coral or fungus.

The estimated yield of the Bath springs is a million tons of water per annum, and this includes very considerable solid deposits, mainly sand. While the radium is too small in quantity for extraction now, better methods of extracting it are hoped for at Bath.

Pacific Cables.

A bill has been introduced in the United States Senate, at Washington, by Senator Mitchell, authorizing the North American Telegraph & Cable Company to operate telegraph lines or cables between the shores of Alaska and Washington, in order to reach the Aleutian Islands, Siberia, Manchuria, China, Japanese Empire and the Philippine Islands.

January Meeting of the American Institute of Electrical Engineers.

In calling to order the regular monthly meeting of the American Institute of Electrical Engineers, which was held in the rooms of the Chemists' Club, New York, January 29, President Arnold announced that at the meeting of the directors in the afternoon action was taken which will insure harmonious co-operation between the Institute and the International Electrical Congress to be held in St. Louis next September. He referred to the annual dinner of the Institute to be held February 11 at the Waldorf-Astoria, and said it promised to be one of the most successful affairs of the kind that the Institute has yet given. In introducing the papers of the evening, President Arnold referred to the great change in sentiment in this country during the past two years on the alternating-current railway motor question, there being at the present time three systems advocated by men in this country and several in Europe.

In presenting his paper, an abstract of which is printed elsewhere, Mr. C. P. Steinmetz said that his purpose was to give a brief history or review of the development of the alternating-current railway motor as far as he can speak from personal experience. The occasion also serves to bring to the notice of those who have not specially followed this line of development the work of Mr. Eickmeyer, now dead ten years, which at the time was hardly noticed, but which with the development of electrical engineering has become of great importance, and indicates how far ahead of his time Mr. Eickmeyer was in his investigations.

Mr. Schlicter, in introducing his paper, which is reprinted elsewhere, said that it is intended largely to be a practical illustration of the motor which Mr. Steinmetz discusses generally and theoretically, and also to offer in curves some experiments made with the motor.

The discussion of the two papers of the evening was participated in by Messrs. Arnold, Lamme, McAllister, Lincoln, Mershon, Armstrong, Lundell, Lyford, Wagner, Torchio, Steinmetz and Schlicter. The remarks of Messrs. Lamme and Steinmetz were of considerable length and will be reprinted in full in a subsequent issue, being here merely epitomized.

Mr. Lamme defined series alternating-current motors as a type in which the field varies automatically with the change in voltage in the armature. This type can be subdivided into two classes, one of which may be called a straight series motor, the armature being in direct series with the field, and the other a transformer series motor. This latter can again be subdivided into two classes, one with the transformer external to the motor and the other with the transformer in the motor. The latter is the repulsion motor and has the characteristics of the series motor. For a straight series motor to have a good power factor, it is necessary to make it as far as possible non-inductive and have the armature voltage relatively low in comparison with the field voltage. The direction in improvement, then, is to increase the armature and decrease the field turns, or increase the armature turns as compared with the field turns. The alternating-current motor of either the repulsion or straight series type is designed to run at low saturation, and at low saturation it will have torque characteristics better than those of an ordinary direct-current series motor, though the latter will give as good torque characteristics with an unsaturated field. The entire proportioning of a repulsion motor for good power factor depends upon high ampere-turns in the transformer element and low ampere-turns in the exciting element.

A transformer type of motor should have poorer starting properties than a straight series motor, and this is indicated by the curves shown in the papers and by tests made. This means that for the same current at starting slightly less torque is obtained than with the series motor, and for the same torque there is a greater ampere input, which may amount to as much as 30 per cent. Comparing the material in the two motors, it would seem that slightly less material is required for the straight series than for the transformer type. In the armature the series motor carries only the working current, while the repulsion motor carries the working current plus the magnetizing current; but as the latter is not in phase and ordinarily may be a small component, it will not be of great importance. In any of the present types of motors so far devised there is a very considerable loss in the short-circuited coil at starting and this will be slightly greater in the repulsion than in the straight series motor. The difference may not be enough to amount to anything, but it is in favor of the straight series motor. As to the flashing of this type of motor, the point has been mentioned that the repulsion motor cannot flash, and Mr. Lamme points out that the same is true of the straight series type.

Mr. Lamme said there is one point connected with the question of high power factor which should not be ignored, which is that a rather high power factor accompanies machines of rather low efficiency, and this is true of all kinds of alternating-current motors. The low efficiency, in fact, to a certain extent, accounts for the high power factors, and the power factor can be increased in any motor by increasing the losses; therefore, in considering the question of high power factors the efficiency should be looked at also. Referring to comparisons between the acceleration of the direct current and the alternating-current motor, Mr. Lamme said that he thought part of the superiority of the latter should be attributed to the unsaturated condition of its working; and that any direct-current motor if working with an unsaturated field will give better accelerating conditions and more economical starting than a saturated motor. The reason for saturating the direct-current motor is to give it lighter weight, while in alternating-current motors we normally work to an unsaturated condition.

Prof. A. S. McAllister referred to a statement of Mr. Steinmetz that the repulsion motor may also be operated as a generator, and he gave a simple graphical method to show why such a motor acts as a generator, and also a graphical method for representing some of Mr. Steinmetz's equations.

Mr. Steinmetz said he was pleased that Mr. Lamme agreed with him concerning the relations of the repulsion motor, the plain alternating-current series motor and the alternating-current series motor fed by a transformer; and he was also pleased that Mr. Lamme had come to the same conclusion at which Mr. Eickmeyer and he had arrived in their early work, namely, that the only way to make an alternating-current series motor operate at reasonably satisfactory power factor is to combine as high armature reaction as possible with as low field excitation as possible, then increasing the ratio of armature to field magnetism, thus eliminating useless current. He did not consider it correct, however, to assume that the armature of an alternating-current motor can be made non-inductive. There is an ultimate limit between the ratio of armature reaction and field excitation, beyond which one cannot go without again losing. Referring to the power factor of the repulsion motor, he said that it is inherently high. In the ordinary induction motor one can use large magnetic saturations, though not nearly the saturations used in the direct-current motor. As to differences in weight and efficiency of the direct series and repulsion motor, if one and the same motor were experimented with at times as a straight series and at times as a straight repulsion motor, a wrong conclusion on this point might be arrived at. A motor which is a good series motor will make a very poor repulsion motor and vice versa. One cannot take one and the same motor and run it first as one and then as the other and draw general conclusions, because the transformer feature introduced requires redesigning of the motor.

Mr. Paul M. Lincoln, referring to a remark of Mr. Steinmetz to the effect that the repulsion motor, when reversed, becomes a generator, and can then be used for braking or returning power into the line, said that the same is true of the straight series motor, as shown in experiments in which a wattmeter indicated that the motor was returning power to the line, and on one occasion, when an airbrake failed, the car was stopped by the motor.

Mr. Mershon asked a number of questions concerning practical points in connection with the repulsion motor, to which Mr. A. H. Armstrong replied. He said that the repulsion motor can be designed to operate on direct current good enough to help through a town along the right-of-way; but that a good repulsion motor and a good direct-current motor cannot be combined in the same structure any more than can a good straight series motor—it is necessary to make sacrifice in one feature or the other.

As to the e.m.f. of the repulsion motor, they can be built for 2,000 or 3,000 volts on the field without the use of transformers, though in this case some advantages in motor control would be lost; however, motors of high potential would hardly be used in service calling for frequent stops, and without frequent stops the small difference in efficiency at starting would have no appreciable effect on the general efficiency of the system as a whole. As to the weight of alternating-current and direct-current motors, the former will weigh some more, but just how much added weight there will be is at present not known. As to the weight of the rest of the equipment, with the case of a high potential motor with 3,000 volts direct on the field, the control equipment would not weigh very much more; with low potentials, however, there would be the added weight of the transformer in addition to the rest of the apparatus.

President Arnold said that the practicability of using high voltages has been pretty thoroughly demonstrated in practice abroad; in Italy, for example, 3,000-volt motors have been operated for two or three years and there has been no report of deterioration of insulation. In reply to a question from Mr. Lundell, Mr. Steinmetz said that comparing the present alternating-current motor of the plain series or repulsion type with the highly developed direct-current motor, the former is somewhat less efficient and weighs somewhat more. He considered, however, that the difference is altogether less than should be anticipated considering the short time of development of one and the long period of development of the other. While at present and perhaps for some years to come the alternating-current railway motor will, as a new type of apparatus, be handicapped by somewhat lower efficiency and somewhat greater weight, Mr. Steinmetz does not consider this inherent in the motor and does not consider it impossible that they will come to a quality with, or even in some cases superior to, the direct-current motor.

Mr. O. S. Lyford having made an inquiry as to the relative dimensions of direct and alternating-current motors, Mr. Schlicter said that a 100-hp motor could be used with a 33-in. or 36-in. wheel. Mr. Lamme added that his company is now building 150-hp motors, which will go in on 33-in. wheels, and that they have concluded that they can put 200-hp motors on 36-in. wheels.

In reply to a question from Mr. H. A. Wagner, Mr. Steinmetz said that the repulsion motor takes more copper and less iron than the direct-current series motor. The straight series motor will have a smaller armature diameter than the repulsion motor, probably larger external diameter, more iron and less copper, but in general he does not expect there will be any important difference between the two types.

Mr. Philip Torchio said he considered that the present traction question is one of distribution, not only for the ordinary kinds of electric railways, but for large trunk lines where heavy traffic is to be handled, and consequently the question of the motor itself is not of paramount importance, provided apparatus can be obtained that will do the work. President Arnold added that if we get an alternating-current motor which will do the work as well as the present series motor, though nothing has been gained, by virtue of the advantage of distribution, a great step forward will have been made. In point of fact the alternating-current and direct-current motors have almost the same efficiency, and with the former is gained the great advantage of distribution inherent in alternating currents. This will enable us to construct electric railways at less first cost than we can do to-day with the direct-current system, and will open up new fields to electric traction.

When and How Incandescent Lamps are Used.

By MORTIMER NORDEN.

The following data has been collated by me showing the yearly consumption of current per 16-cp lamp on the circuits of a large central station company, giving the yearly average of current used in kw-hours. I believe that many of your readers will be interested to see this analysis at the time of the twenty-fifth anniversary of the incandescent lamp. The data represent ten plants all operated by the one company:

Totals of Average Consumption, Showing Yearly Consumption per 16-cp Lamp Connected.

		Lights.	Kw-hours.

Statistics of Export Trade.

The figures of 1903 in United States export and import trade have already been noted in these pages, and now further details as to this record year are obtainable. For the twelve months ending December 31 the exports of domestic manufactures amounted to \$421,453,915, against \$410,650,967 in December, 1902, an increase of \$10,802,948. The increase for December alone was thus more than one-half of the total increase for the calendar year. In 1902 many of the leading articles of export fell behind the record for the previous calendar year. The most notable decline was in the exports of cotton cloths, which fell off about \$7,000,000. Exports of copper manufactures fell off about \$2,000,000, and exports of vegetable oils about \$3,000,000. The most notable increase was that of about \$5,000,000 in exports of agricultural machinery. Other important increases were \$3,000,000 in the exports of refined mineral oils and \$1,000,000 in steel rails.

The following table shows the values of exports of some of the leading articles of domestic manufacture during the twelve months ending December 31, 1903, as compared with the same period in 1902:

Articles—	1902.	1903.
Agricultural implements	\$17,981,597	\$22,951,805
Books, maps, etc.	4,407,028	4,336,732
Cycles and parts	2,581,255	2,099,092
Automobiles and parts	1,069,782	1,643,029
Cars, carriages, etc.	7,500,064	8,506,092
Clocks and watches	2,121,657	2,216,346
Copper ingots and manufactures	45,485,598	43,509,788
Cotton cloths, colored	8,838,724	6,395,219
Cotton cloths, uncolored	18,030,589	13,337,851
Fibre manufactures	5,111,865	5,642,405
Glass and glassware	2,094,701	2,053,516
Gunpowder and explosives	2,393,480	2,367,148
India rubber manufactures	3,815,754	4,360,965
Electrical and scientific apparatus	6,466,201	8,145,923
Steel rails	1,902,396	937,779
Structural iron and steel	2,828,460	1,788,556
Steel wire	5,140,702	5,528,726
Builders' hardware	11,320,765	12,141,058
Miscellaneous castings	1,685,660	1,765,901
Cash registers	1,220,791	1,825,503
Electrical machinery	5,937,643	5,104,502
Metal working machinery	2,863,709	3,316,088
Pumps and pumping machinery	2,516,300	2,729,288
Sewing machines and parts	4,606,794	5,340,474
Locomotive engines	3,966,007	3,099,521
Boilers and parts of engines	2,432,098	2,273,834
Typewriters and parts	3,575,909	4,537,396
Miscellaneous machinery	20,930,519	20,068,810
Iron pipes and fittings	5,107,183	5,919,340
Miscellaneous manufactures of iron and steel	10,052,766	9,073,059
Sole leather	6,720,966	6,320,665
Upper and other leather, except sole	16,099,430	17,376,746
Boots and shoes	6,470,412	7,244,726
Muscial instruments and parts	3,437,337	3,354,108
Naval stores	13,299,861	14,299,296
Refined mineral oils	62,266,132	65,846,389
Vegetable oils	16,203,002	13,160,379
Paints, pigments and colors	2,219,438	2,566,936
Paper and manufactures	7,251,517	7,339,914
Paraffine and wax	8,398,450	9,596,308
Soap	2,028,264	2,627,633

Articles—	1902.	1903.
Tobacco manufactures	5,523,234	5,204,407
Wood manufactures	12,437,864	13,634,065
Woolen manufactures	1,588,058	2,002,913

The showing for electrical apparatus and machinery, etc., will be noted in particular. Taken together the two items show a total of $13,250,425, as compared with $12,403,844 in 1902. Part of the apparatus is scientific other than electrical, but the general showing is splendid. The slight falling off in electrical machinery value is attributed to the lower range of prices prevalent, but not to any decline in bulk. There is great encouragement in these statistics for electrical manufacturers in pushing for foreign markets. Many of the other items on the list include or conceal material of an electrical nature or purpose.

Vapor Tube Telephone Repeater.

In a patent issued January 19 Mr. Peter Cooper Hewitt describes an important application of the vapor tube for reproducing variations of current in an electric circuit, the latter being either wholly independent or a branch of a divided circuit. The striking feature of the principle is that it enables the production in the secondary circuit of electrical variations of greater magnitude than the original electrical variations in the primary or transmitting circuit. In other words, it offers a solution to the problem of the telephone repeater. As illustrated and described, a magnet in the telephone transmitting circuit is in close proximity with a vapor tube, and the telephone receiving device is in series in the vapor tube circuit. In one form shown the core of the magnet in the transmitting circuit embraces the vapor tube. It is stated that the amplification of the electrical variations in the secondary circuit is due to the fact that a given magnetic variation may cause a wider fluctuation of effective resistance in the gas or vapor than the fluctuations of electrical energy producing the variation of the magnetic field of force. Accordingly, by employing the vapor tube the vibrations of the circuit are magnified, not by induction effects, but by varying the ohmic resistance of the circuit in which the apparatus is placed.

CURRENT NEWS AND NOTES.

ATLANTA BRANCH A. I. E. E.—Plans are being made for the organization in Atlanta, Ga., of a branch of the American Institute of Electrical Engineers.

ELEVEN CENTS PER K. W.—Eleven cents per kilowatt will be the maximum price which is to be charged by the Cincinnati Gas & Electric Company during the next ten years. This scale has been fixed by the city council.

TRANSMUTING METALS.—In a speech on radium at the Hotel Cecil, London, on January 23, Prof. Sir William Ramsay hinted that his recent discovery would possibly open up the question of the transmutation of one element into another. He did not mean to say that silver and copper were transmutable into gold, but it might very well be asked what would happen if gold were made very much cheaper.

ELECTRICAL POSTAGE STAMPS.—King Victor Emmanuel is of opinion that the Italian stamps are not sufficiently artistic, and has, therefore, decided to issue a completely new set of stamps. The new stamps are said to be remarkably artistic and there is a different design for each value. Two of the most interesting stamps are those of one and two centimes, for the first bears the head of Volta and the second that of the modern electrician, Marconi, the inventor of the wireless telegraph.

KAISER HONORS ELECTRICITY.—A cable dispatch from Berlin of January 29 says: "In recognition of their services to the State, Emperor William has had decorations conferred upon Dr. Schulz, president, and Herr Rathenau, general manager, of the General Electrical Company, of Berlin; Herr Denninghoff, manager of the Society for Experimentation in Rapid Electrical Transit, and on several engineers who have been connected with the recent experiments."

PARIS SUBWAY LINES.—Another fire, caused by the short circuiting of the electric current of a train on the Metropolitan Railroad, occurred on January 30, near the La Chapelle Station. A panic followed, in which four persons were injured, none of them seriously. Boring operations in connection with the new Metropolitan line from Courcelles to Menilmontant, which crosses the Place de l'Opera, have been completed, and the work of laying the rails has been begun. The cars will be larger and safer than those now in use, and a tunnel has also been constructed, so as to have a grand station at the Gare Saint Lazare, connecting the Metropolitan with the Western Railway and the Ceinture. The inauguration of the line is expected in July.

IMPORTATION OF CURRENT.—According to advices from Niagara Falls, the question of the exportation of electricity from Canada to the United States has reached a point where it must be decided one way or the other. A deputation, consisting of W. B. Rankine, vice-president. and M. Munro Grier, secretary, of the Canadian Niagara Power Company; J. W. Langmuir, chairman of the Queen Victoria Park Board; G. T. Blackstock and W. Caryl Ely, of the International Railway Company; H. H. McRae, of the Electrical Development Company, and A. W. Maltby, of the Ontario Power Company, have interviewed Premier Ross on the situation. The International Railway Company has made application for permission to bring electric power from its power house on the Canadian side of the river to this side and use it to operate its cars.

RADIUM AND CANCER.—A cable dispatch from St. Petersburg, of January 27th, says: "Prof. Prince Tarkhanov, a well-known scientist, lecturing recently before the Military Association, made some interesting statements in regard to the possibilities of radium. He presented to his audience two cancer patients who had been cured of malignant growths on the face by the use of radium, and expressed the opinion that the problem of determining the sex of children, which Professor Schenck had failed to solve, will soon be settled by the aid of radium. The prince added that he had prevented the development of hydrophobia in dogs inoculated with the virus of rabies, by using radium. When large quantities of radium were available, the prince contended, the whole system of modern warfare would be revolutionized, as powder magazines, whether in forts or in the holds of vessels, would be at the mercy of radium rays, which could explode them at long distances."

MORE THIRD RAIL ROADS.—There appears to be a good deal of activity in various parts of the country in developing third rail enterprises. A corporation to be known as the Minnesota Central Railway Company is being organized by John J. Allen, J. Quist, and others of Minneapolis; F. B. Rossom, of Virginia, prominent in iron land matters on the Mezaba, and some Eastern capitalists. The plans of the company are to build an air line from the twin cities to Duluth and operate it by electricity. It is to be a standard gauge road, and will be 135 miles long, seventeen miles shorter than the Northern Securities roads, the Great Northern or Northern Pacific lines, between the points named, and will be a rival of them for business. Last week also announcement was made that arrangements have been concluded for the building of a third rail street car system between Elmira, N. Y., and Corning. The necessary application will be made to the State Railroad Commissioners at once. A private right of way has been secured and only one grade crossing will be made.

ELECTRIC POWER FOR FACTORIES.—One of the most important lines of work undertaken lately by the National Electric Light Association deals with the sale of current for power purposes by central stations. Of late years the day circuit and the motor load have become vital features of progressive development in the industry and now, on every hand, there is inquiry for fuller information on all branches of the subject. Having this in mind, President Edgar has appointed, on behalf of the association, a committee to obtain and present data in regard to "Purchased Electric Power in Factories," and W. H. Atkins, chairman of the committee, is issuing a circular of inquiry which is well calculated to elicit a large amount of valuable data. Mr. Atkins can be addressed at 3 Head Place, Boston. The other members of his committee are Messrs. S. M. Bushnell and G. W. Brine. It is hoped and believed that responses will be copious and numerous, so that the report will give a further stimulus to the sale of current for power as well as extend the application of motors on central-station circuits. The useful work that the Association thus attempts and carries out so well is highly beneficial to the art, and should have a reflex action in increasing its influence and membership.

THE INVENTION OF THE TELEPHONE.—The newspaper press has once again returned to the subject of priority of invention of the telephone. The story is that in 1901 Judge Kohlsaat, of the United States Circuit Court at Chicago, appointed a special examiner to take evidence in the suit for $50,000,000 damages brought by the Atlantic & Western Telephone Company against the American Bell Telephone Company, American Telephone & Telegraph Company, Chicago Telephone Company, and the Central Union Telephone Company for alleged infringements on Henry C. Strong's inventions. A few days ago the examiner, it is stated, filed testimony tending to deprive Prof. Bell of the credit of inventing the telephone and bestowing the honor upon Strong. According to a dispatch from Chicago, the basis for the suit is an invention to facilitate long-distance telephoning, for which Strong secured a patent in 1885. Strong is nearly 80 years of age and a resident of Chicago.

LETTERS TO THE EDITORS.

Theories in Wireless Telegraphy.

To the Editors of Electrical World and Engineer:

SIRS:—The letter and extracts from M. Blondel's paper published in your issue of January 2nd last afford interesting reading in view of the statements which have sometimes been made imputing priority of publication of the sliding wave theory to M. Blondel. If refutation of Mr. Fessenden's statement ascribing such priority in any degree to M. Blondel were needed, a more admirable answer could not have been forthcoming. M. Blondel's theory, as I have always been fully aware, is *not* mine. It differs in the vital point that his theory involves space-propagated radiation whereas my theory is essentially a theory of surface-propagated or sliding waves. The one does not to any extent account for the great range over which signals can be detected, whilst the other supplies an obvious and simple reason for the effects observed. At the time that I originally framed my theory I need hardly say I was quite unaware of M. Blondel's work, but the theory which he advances was at once so obvious that it was given full consideration and dismissed as not affording a rational explanation of the various phenomena observed. I have therefore no intention whatever to lay claim to a theory to which M. Blondel is so very welcome.

Before baldly referring to my "erroneous ideas" it would savor of better judgment on M. Blondel's part if he took the trouble to prove the existence of the errors he so groundlessly imputes to me, as statements of this kind cannot but be resented unless substantially backed up, whether made by M. Blondel or Mr. Fessenden. I contend most emphatically that it is they who are in error.

In the first place, M. Blondel's theory, despite his statements to the contrary, does not fit in with the facts elucidated by experiments. It is plain from the diagram given of the wave distribution that at quite moderate distances from the transmitter the intensity of the effects produced on a vertical antenna will not materially diminish at very considerable heights above the surface of the ground on this theory. So long as the plan of polarization is sensibly vertical the action on a vertical antenna dependent from a balloon will remain constant whatever be the height. I am not aware that this is in accord with experiment. In the second place the theory involves a denial of the fact that Hertzian waves can be guided by conductors, for, if waves on wires expand as M. Blondel would have them, there is nothing whatever to distinguish them from the ordinary free or space-propagated Hertzian waves which spread through space somewhat in the manner indicated in the theory.

It is certain, therefore, that waves on wires such as were investigated by Hertz himself and by Von Bezold before him have not any such form. Inasmuch as wires prevent the dissipation into space of waves which they conduct it is abundantly clear that two distinct classes of waves are concerned, and this was fully recognized by Hertz as indicated in the diagrams given on page 156 of the English translation of his papers, 1893 edition. If, then, waves on wires differ in form from space-propagated waves there is surely every reason, apart from experimental evidence, for the assumption that wireless telegraphy waves where the surface of the earth replaces the conducting wire are rather of the type of waves on wires than of space-propagated waves.

I fully appreciate the considerations which lead M. Blondel to his view of the case and to the idea that the waves must expand vertically as well as laterally. To some small extent this must be the case, especially when the wave train is a very short and rapidly-damped one, but the effect will generally be quite negligible. Consider the case of an electric shadow thrown by a large conducting obstacle in the path of the waves. The existence of the shadow proves that the expansion of the waves into the region of the shadow after passing the obstacle is not a necessity. Of course, diffraction effects come into play, but if the size of the object be sufficient in relation to the wave length these effects become negligible. Here there is a perfectly analogous case so far as the tops of flanks of the waves are concerned. Indeed, it is a question of the application of Huygens' principle, which is really at the bottom of the matter.

The peculiar way in which M. Blondel makes his lines of force twist and squirm in their frantic endeavors to form a true expanding hemisphere is decidedly quaint and would do them credit if it were true.

I do not for a moment claim infallibility, and I should like to take this opportunity of pointing out a slight inaccuracy which appears in one part of my original publication in the London *Electrical Review*, and which I have for a long time past fully intend to correct. It is, however, just the part which has been accepted as gospel on all hands and which has also been ascribed to Hertz as Hertz's conception of wave formation. I have, however, no desire to palm off my mistakes as those of Hertz. The misconception alluded to is that regarding the ends of the lines of force as gliding along the oscillator or antenna in the formation of self-closed fields of force which are resolved into waves. Strictly speaking there is no lateral motion of the lines of force *at the surface of the oscillator*, at any rate after the oscillations are fully established, a fact which I find Hertz recognized (see page 255 of Hertz's papers quoted above); for if such a motion be assumed it becomes necessary to make the further assumption that the rate of movement is infinitely rapid, thus destroying the value of the conception.

I propose to explain this point more clearly in a further publication shortly, but will here merely point out that although strictly correct as applied to the conception of travelling waves the lateral motion of the lines is not a true explanation of the effects taking place at and near the oscillator itself. In other words it does not properly apply within the quarter-wave-length range about the oscillator or the resonant receiver, either with respect to the electric or the magnetic lines of force. The result arrived at is correct, but the method of deduction is not quite accurate. This may appear foreign to accepted notions on the subject and is rather hard on the electron theory as applied to wireless telegraphy, but I am fully prepared to substantiate the statement.

Another point on which I entirely disagree with M. Blondel. He assumes for obvious reasons that the speed of propagation of wireless waves is not the same as that of light until they have proceeded a large number of wave-lengths from the source. This is in conflict with known laws. The speed of propagation is that of light at distances beyond the first quarter-wave length or thereabouts, provided disturbing factors in the way of reflection, opposing wave-trains, resonance effects, etc., are absent, and that the medium is perfectly homogeneous.

LONDON, ENGLAND. J. E. TAYLOR.

"Cannon Ball Trolley Cars."

To the Editors of Electrical World and Engineer:

SIRS:—Your query, "Why 'cannon-ball'?" at the conclusion of your note entitled "Third Rail in Pennsylvania," and citing that epithet calls forth a reply that may be of interest. The introduction of the high-speed interurban electric line by the Lackawanna & Wyoming Valley Railway Company was an epoch-marking event for this section of the State. Although such a road had been in operation between Hazleton and Wilkesbarre, it does not seem to have elicited as much comment as the L. & W. V. R. R. Prior to its christening that road was known as the "Cannon Ball," presumably on account of the fanciful notion held by this provincial community that the speed of the cars rivalled that of an ordnance projectile. As a result of a prize contest the road was named the Laurel Line, but in spite of advertising under that name, "the Cannon-Ball road" is still its vernacular title.

The distance from Scranton to Wilkesbarre is 19 miles, and is covered in about 43 minutes by both the Laurel Line and the D. & H. R. R. The former has the advantage of better service and so gets a large part of the traffic. Its rate of fare is 50c. for the round trip. That on the D. & H. R. R. was formerly 85c., but the decrease in traffic due to the inroads made by the Laurel Line caused a reduction of fare to 40c. for the round trip. That did not have the effect of winning back the former business, so it has been apparently decided to fight the newcomer with its own weapon.

In confirmation of the current belief comes the announcement that the Lehigh Valley R. R. (or in other words the Pennsylvania R. R.) will use the tracks of the Laurel Line to provide service in connection with their principal express trains. For years the "P. R. R." has sought entry into this city, and now it has it over a well-built double-tracked road, capable of withstanding heavy traffic and high speeds.

Scranton, Pa. L. S. Levy.

DIGEST OF CURRENT ELECTRICAL LITERATURE.

Dynamos, Motors and Transformers.

Double-Current Generators.—Horschitz.—A mathematical article illustrated by diagrams in which he discusses the copper losses in double-current generators. While a double-current generator is quite similar to a synchronous converter, yet there are two main distinguishing features. The two currents in the converter have opposite directions, while they have the same direction in the double-current generator. In the converter the alternating-current energy is nearly equal to the direct-current energy, while this is not the case in the double-current generator. The author discusses in detail in which way the current in every armature coil is resolved into the direct and alternating currents, which are taken off from the machine. He shows which copper losses and heating are produced by this combination in the whole armature and he compares these losses with the losses which would occur, if the armature would give only direct current. For the double-current generator, when operated on a non-inductive load, he reaches the following conclusions: If generating single-phase current, the losses are very great, as soon as the alternating-current load is 25 per cent. of the maximum possible direct-current load; and the greater the single-phase load becomes the greater become the losses. A double-current generator, giving three-phase and direct-currents, is economical as long as the apparent three-phase power is not beyond 67 per cent. of the maximum possible direct-current power; that is, for instance, as long as an armature which can give 100 kw direct current has not to furnish more than 67 kw, three-phase currents at a power factor equal to unity. The more phases are used the smaller become the copper losses; but there is no use to increase the number of phases beyond six. If the double-current generator is operated on an inductive load, the copper losses become smaller than in the former case.—*Elek. Zeit.*, January 14.

Single-Phase Motor.—An illustrated description of the Schüler-Ferranti single-phase motor, which is a combination of an ordinary

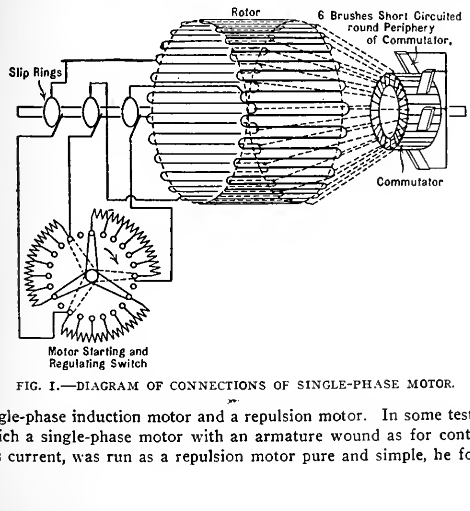

Fig. 1.—Diagram of Connections of Single-Phase Motor.

single-phase induction motor and a repulsion motor. In some tests in which a single-phase motor with an armature wound as for continuous current, was run as a repulsion motor pure and simple, he found the starting torque to be good, but to decrease rapidly. On the other hand, when the same motor was run as a single-phase induction motor with a three-legged resistance in its rotor circuit, the torque is zero at start, but increases gradually to a maximum. This behavior is exactly opposite to that of the repulsion motor. Schüler combined, therefore, these features of both types of machines in one motor and the outcome is the arrangement shown in Fig. 1. At any speed the motor torque is approximately equal to the sum of the torques due to the repulsion motor and to the induction single-phase motor, respectively. This feature is shown in the curve of Fig. 2. At starting the three-legged resistance is inserted in full in the

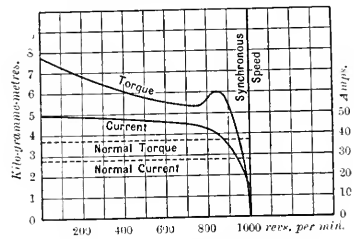

Fig. 2.—Characteristic Curves.

rotor circuit, and the current flows by way of the commutator and the short-circuited brushes. The motor then starts as a repulsion motor. By gradually cutting out the starting resistance, part of the induced armature current flows through the resistances and the motor begins to act as an ordinary single-phase induction motor. By means of the three-legged resistance, the motor speed may be varied in wide limits, the torque varying to a comparatively small extent.—Lond. *Elec.*, January 15.

Single-Phase Commutator Motors.—Osnos.—The conclusion of his long illustrated article in which he discusses the various forms of single-phase commutator motors. After having described the compensated series motor and the compensated shunt motor, he discusses the methods of regulating the speed and torque, of changing the direction of rotation and of avoiding short-circuit currents in the various types of motors discussed by him.—*Elek. Zeit.*, January 14.

Lights and Lighting.

Arc Light for Photochemical Purposes.—An article in which it is said that for photochemical purposes (making blue prints, etc.), the ordinary arc lamp is uneconomical. An arc lamp of a German company is described which is claimed to be specially suitable for such purposes. It is an enclosed arc lamp, the life of the carbons being given as 250 hours. By carefully keeping the air away and using a high-voltage (say, 200 volts direct current) an arc of 25 to 30 mm. is obtained, which is chemically very active. With such a special 200-volt lamp the consumption of current for the same chemical effect is claimed to be less than one-fourth for the ordinary 55-volt lamp.—*Zeit. f. Beleucht.*, December.

Electric Arc Between Carbons.—Blondel.—A long article in which the author summarizes and critically discusses the work of Mrs. Ayrton on the mechanism of the electric arc between carbon electrodes.—*L'Eclairage Elec.*, January 2, 9.

Mercury Arc.—De Valbreuze.—A fully illustrated article in which the author gives a summary of the various investigations on the electric arc through mercury vapor.—*L'Eclairage Elec.*, January 16.

Power.

Blast Furnace Gas as a Source of Power.—An illustrated description of the Thwaite system for using the blast furnace gases, now largely wasted, for driving gas engines and generating electric power. In an editorial on this subject it is pointed out that about 50 per cent. of the effluent gases of a blast furnace are available for use for other purposes than those connected with the operation of the furnace itself. For every ton of pig iron produced per hour about 840 hp is available for other uses. Considering the immense production of pig iron at many plants, it appears that these plants are bound to become centers of generation and distribution for large amounts of power in their vicinities.—*Power*, January.

References.

Electric Pumps and Compressors.—Richard.—In a continuation of his serial on mechanical applications of electricity he gives brief, concise and illustrated descriptions of various electric pumps constructed during recent years, especially for use in mines and metallurgical plants. Among the apparatus described are the pumps of Deane, Knowles, Mavor & Coulson, Merryweather, Hammersmith. There are also described several air compressors for use in connection with compressed air brakes in traction, compressors of Christensen, Batchelder and the Thomson-Houston Company being described.—*L'Eclairage Elec.*, January 2.

French Water Power Plant.—Domar.—An illustrated description of the plant of the Electrometallurgical Society of Saint-Beron. It contains five turbine-driven, two-phase generators, giving 3,000 or 6,000 amp. at 80 or 40 volts, respectively. They supply 12 electric furnaces for making calcium carbide.—*L'Eclairage Elec.*, January 16.

Shawinigan Falls.—Perkins.—An illustrated description of recent equipment for the power house of the Shawinigan Falls Power Company.—*West. Elec.*, January 23.

Superheated Steam.—Buhle.—An illustrated description of the Pielock system of superheated steam.—*Dingler's Polytech. Jour.*, January 2.

Traction.

"Electrothermic" Operation of Railways.—Lengenhazer.—An illustrated article on a peculiar system which is said to be now under consideration by the general management of the railways of Switzerland. The main idea is to retain the old locomotives, but to produce the heat for heating the water not by burning coal, but by the electric current in resistance, properly arranged, so as to get a very high efficiency for the transformation of electrical energy into heat. For this purpose the resistances consist of extremely thin layers of "noble metals," burned into mica plates, so as to have a very small cross-section and a very large surface. If the boiler has a capacity of 4,000 liters water it is calculated that to heat them from 10° to 190° C., corresponding to a steam pressure of 15 kg. per sq. cm., 300 kw are required. For a steam consumption of 1,000 kg. per hour, about 225 kw would be required. The following advantages are claimed for this system. When a train starts there is no sudden increase in current consumption, so that the load curve is more uniform. Direct or alternating current may be used. The regulation of the heat is very simple, since only resistances are inserted to or switched off from the circuit. The present railway engineers would easily become acquainted with the new system.—*Elek. Anz.*, January 7.

Jackson & Battle Creek Railway.—A description of this new third-rail road, 45½ miles in length, recently put in operation in Michigan and operating cars at a maximum speed of 60 miles per hour. The third rail weighs 70 pounds per yard and is used throughout the line except in the cities, where the overhead construction is employed. Power is purchased from a water power plant located 45 miles from one terminus and 90 miles from the other terminus, and is transmitted at 40,000 volts and 60 cycles. Rotary converters are used in the substations. The railway company pays 1¼ cents per kw-hour for the first 3,000 kw-hours per day, and after that at the rate of one cent per kw-hour.—*St. R'y Jour.*, January 2.

Rail Bonds.—Harrington.—The first part of a fully illustrated Franklin Institute paper on rail bonds. As the vital features he considers: primary, life and conductivity; secondary, cost and design. He describes types of bonds which now represent the best practice in the United States, and starts with a discussion of protected rail bonds.—*Jour. Frank. Inst.*, January.

Sheffield.—Sample.—An illustrated description of the trolley system of Sheffield, England, which comprises 29 miles of double-track and 7 miles of single-track. The nominal capacity of the power plant is 3,675 kw.—*St. R'y Review*, January 20.

Seattle.—A fully illustrated article on the "Stone & Webster properties on the Puget Sound," and especially the Seattle Electric Company, which does the electric railway lighting and power business of Seattle. The company has eight power stations, the equipment of which is described. The traction system is dealt with at length.—*St. R'y Review*, January 20.

Tram Cars.—Herzog.—The first part of an article on the construction of cars built by Swiss companies for electric tramways. Some detailed drawings are given.—*Zeit. f. Elek. ü. Masch.* (Potsdam), January 16.

Installations, Systems and Appliances.

Electromechanical Compounding System.—Brock.—An illustrated description of the electromechanical compounding system of Routin. In the regulation of steam-driven dynamos, the speed must be adjusted by varying the admission of steam to the engine and on the other hand the voltage must be varied by changing the excitation. Both changes should be made simultaneously, but the changes of admission of steam require time, since the mechanical devices are subject to the law of inertia. The condition for the successful regulation is, that with increasing current consumption and with decreasing voltage or decreasing speed, the admission of steam should be increased and the excitation simultaneously increased, while with decreasing current consumption and increasing voltage or speed, both the admission of steam and the excitation should be diminished. The device of Routin, as shown in Fig. 3, consists of an iron

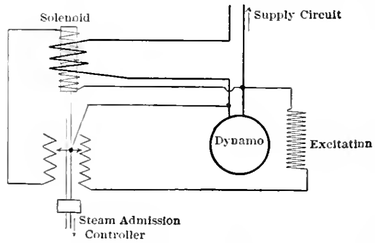

Fig. 3.—Electromechanical Compounding System.

core, on which is acting the difference of the ampere windings of a main current coil and of a voltage coil. Through the main coil flows the current given out in any moment from the machine, while the shunt coil (which is connected in opposition to the main coil), is connected across the terminals of the generator is in series with a resistance which may be regulated by the sliding contact, *a*. Simultaneously with the sliding contact, *a*, the sliding contact, *b*, moves which, by its changed position on the resistance, *R*, influences the excitation of the machine. The dimensions of the coils are so chosen that the action of the shunt coil is always superior to that of the main current coil. The iron core of the solenoid is coupled to the devices which determine the steam admission to the engine, and carries a weight, *P*, which gives an attractive effort downwards. When the iron core sinks downwards the steam admission is increased, and if it rises upwards the steam admission is diminished. The motion of the iron core is the result of the differential action of the two ampere windings.—*Elek. Zeit.*, January 14.

French Gas-Driven Power Plant.—A note on what is considered to be one of the largest gas-driven power plants in France. It is the plant in Valenciennes which was formerly operated by steam, but has been converted to a gas-driven one in consequence of a dispute arising with the local gas company with regard to certain concessions held by the company. A settlement was arrived at, the electric company agreeing to a minimum purchase of 50,000 cu. m. of gas per year at a price of 2 cents per cu. m. Four 110-hp gas engines have been erected in the engine room and they are remarkable for the fact that one of the two cylinders, which are mounted in tandem, is double-acting, the other being single-acting. They drive four direct-current dynamos, each giving about 400 amp. at a voltage of from 225 to 250. A smaller set of about 40-hp capacity is used in connection with the buffer battery and for light loads. The three-wire system of distribution is used and electricity is sold for lighting at a price from 11 to 15 cents per kw-hour, and for power purposes at a price of 7 to 10 cents.—Lond. *Elec.*, January 15.

Electric Installation on Board Ship.—A very long and profusely illustrated description of the Chilian battleship *Libertad*. The following information is given concerning the electric equipment. The use of incandescent lamps throughout the vessel is most complete. The total number of lamps is about 1,000—generally of 16 cp—with 50-cp lamps in clusters on the yard arms, and lamps of 50 cp for the coal bunkers. There are five dynamos in the vessel, each of 500 amp. at 100 volts, when running at 400 revolutions, together with the necessary engines, these dynamos being all coupled up to the switchboard by specially insulated cables. The switchboard is suitable for parallel running, is capable of dealing with the total number of dynamos and circuits required, and fitted in a position adjacent to the dynamos, easily accessible and convenient as regards manipulation of switches and other necessary work at the switchboard. The circuits are distributed by means of specially insulated cables to gun metal section boxes, which boxes feed the water-tight distributing or cut-out boxes, from which the lamps are controlled. In addition to the above, there is a rotary transformer, the whole being arranged so that the complete electrical equipment is entirely under the manipulation of one engineer. Five powerful searchlights of a special pattern are fitted, and generally arranged so that they can be withdrawn into cover during action or stress of weather. All the projectors are provided with automatic feed lamps and mirrors on the Mangin principle. In addition to the electric lighting plant there are about 70 electric motors in the vessel, generally for ventilating purposes; electric ammunition hoists are also arranged for the 7½-in. guns, and, wherever suitable, electrical power has been applied so as to reduce, as far as possible, manual labor on board.—Lond. *Eng'ing*, January 15.

Electric Installations on Board Ships.—LEBLOND.—The first part of what appears to become a long serial discussing in detail the design of electric installations on board ship and emphasizing those points in which such installations differ from installations on land. For instance, while on land always one central station would be used to distribute electricity over a comparatively small area, there are often two separate plants on board ship. Direct current is always used and while formerly the voltage was 70 or 80 it is now the intention in France to use in future 120 volts.—*L'Ind. Elec.*, January 10.

ELECTRO-PHYSICS AND MAGNETISM.

Electric Oscillations.—WAGNER.—An article in which the author endeavors to give in concise form the foundation of the theory of physical phenomena in the transmitting and receiving apparatus for wireless telegraphy. He gives the fundamental differential equations and their general solution for waves along a straight wire and in a closed oscillation circuit.—*Dingler's Polytech. Jour.*, January 16.

Radioactivity.—CURIE.—A long summary of recent researches on radioactivity. The subject is dealt with under the following headings: Radioactive substances; the different rays given off; heat developed by the salt of radium; induced radioactivity and radioactive emanations.—*Jour. de Chimie Phys.*, December.

ELECTRO-PHYSICS AND MAGNETISM.

Electrolytic Stripping of Metals.—BURGESS.—An illustrated article on the method of removing brass from iron. A number of years ago, when the manufacture of bicycles was in its most prosperous stage, an important department in each factory was that devoted to filing, where the thin layer of brass on the surface of the frames was removed by a corps of workmen stationed at benches around the room. Later, however, the filing room was changed to an electrolytic stripping room, since the latter method was found to be much more economical and convenient. The method itself is described in detail and the tanks and special fittings for the treatment of the bicycles are illustrated. The gist of the method is that the brass-covered iron is placed as anode in a sodium nitrate solution; when the current passes from it toward an iron cathode, the zinc and copper are completely removed, while the iron which is in its passive state is left smooth and bright. The current density is between 5 and 15 amp. per sq. ft., while the pressure required is 3 to 5 volts. Silver, copper, tin, zinc, lead, cadmium and the various alloys can be removed from iron in this way and this points out various other applications of the process. It offers a convenient and rapid method for removing silver from plated articles of iron, which are to be re-silvered and also for removing silver from suspension rods, hooks and baskets used in silver plating, thus not only recovering the suspension devices themselves, but the silver as well. Files which have been used upon brass, copper, lead or other soft metal and have become clogged may be quickly and effectively cleaned by suspending them as anode in a sodium nitrate solution. A layer of tin on tinned iron may be removed completely in a few minutes in the same manner without dissolving any of the iron.—*Electrochem. Ind.*, January.

Manufacture of Steel in the Electric Furnace.—BENNIE.—A fully illustrated article on the process of Gin for the electric manufacture of steel in a resistance furnace of special design. The furnace used is in form of a channel of great length and small cross-section, filled with fused cast iron and having at its terminals blocks of steel cooled by an internal current of water. The passage of the proper amount of current in the conductor of fused metal sets free a sufficient quantity of heat to maintain the whole mass in fusion, and to bring it to the most favorable temperature for producing the refining reactions. The large section of the blocks forming the terminals of the circuit prevents a great rise of temperature in them, being aided in this respect by the circulation of cold water. To give a convenient form to the hearth, the channel in which the metal is held is doubled on itself several times, so that there is formed a sort of huge incandescent lamp, of which the filament consists of a stream of molten iron. In practice the furnace is carried on a movable carriage on wheels in an arched furnace, the fused pig iron being introduced from the latter into the electric furnace. There are two essentially different methods of operation, the one being the "dilution method" (scrap process) in which the calculated proportion of scrap iron is added to the fused bath in which it dissolves. The carbon diffuses with great rapidity throughout the mass and the conversion of the whole into steel takes but very little more time than that needed for the fusion of the added metal. The other method is to add some iron oxide (ore process); the oxygen of the iron oxide added to the bath burns the silicon, manganese and carbon. A mixed method involves the use of a certain amount of scrap and oxidation by the addition of iron oxide. The pig iron is treated with some iron ore and lime, so as to oxidize the impurities while producing basic slag, which facilitates the elimination of the phosphorus. When the purification is sufficient the scrap iron is introduced into the very hot bath, the slag is removed when fusion is complete, and the final additions of ferromanganese are made, to reduce the oxide dissolved in the metal. The use of this mixed process depends upon the nature of the possible supply of raw materials. The process is thought to be well adapted for the manufacture of special steels. An example of the application of the process of oxidation is discussed at length and some data are given on the cost of the process. —*Electrochem. Ind.*, January. An illustrated article by Gin on this same process is given in *L'Eclairage Elec.*, January 9.

Action of Sodium and Potassium Amalgams on Various Aqueous Solutions.—FERNEKES.—A long account of an experimental investigation on this subject in which he reaches the conclusion that the electrolytic dissociation theory is unable to explain the facts. He gives an explanation based on Kahlenberg's hypothesis that a theory of solutions is to be based on chemical affinity, the affinity between solvent and dissolved substance, and the formation of a true chemical compound whose properties are different from either constituent. The author believes that an explanation of the various catalytic actions can be given on the basis of this theory.—*Jour. Phys. Chem.*, December.

Electrotypes.—COWPER-COLES.—An illustrated description of various methods, mainly taken from patent specifications or trade publications, for rapidly producing electrotypes. Some kind of agitation is necessary and the following four methods are distinguished: The electrolyte is circulated and at the same time agitated; the electrolye is circulated only; it is agitated only; the electrodes are moved;

the electrolyte is circulated and filtered.—*Electrochem. & Met.*, December.

Units, Measurements and Instruments.

Double-Tariff Meter.—A note on an instrument of an English company for registering electrical energy supplied at a double rate of charging, according to the hours of the day during which energy is consumed. It consists of two watt-hour meters of any make and a contractor clock. On the arbor, to which the hands are attached, are mounted two cams, these actuating two contact springs. By setting the cams suitably, the shunt circuits of the two watt-hour meters are opened and closed by the contact springs at the pre-determined times. The clock is made to run for one month with one winding. One of the meters referred to registers the total number of units consumed, while the other marks the number of units sold during any particular period. All the contacts of the contactor are on the front of the clock, and periodical inspection may be made without disturbing the seals. These double-tariff meters may be used either for continuous or for alternating current.—Lond. *Elec.*, January 15.

REFERENCE.

Selenium Cells.—An illustrated description of various forms of selenium cells and apparatus made by Ruhmer. A practical application of the same is the use of a selenium cell in combination with a relay for automatically lighting and turning off gas and electric light, when it gets dark or with the coming of dawn. Whether such an apparatus is used in real practice is not stated.—*Elek. Anz.*, December 17.

Telegraphy, Telephony and Signals.

The Antenna in Wireless Telegraphy.—Chant.—A fully-illustrated account of an experimental investigation on the variation of potential along the transmitting antenna in wireless telegraphy. In the simple Marconi method and the method of direct excitation, when the antenna is joined to earth, the effect is similar to using a wire the same as the antenna to balance it; that is, considered from an optical point of view, the earth acts as a plane mirror. In these conditions the chief oscillation is the fundamental of the antenna, with a wave length four times its length. The condenser circuit in the method of direct excitation impresses its wave length on the antenna, but its oscillations are not nearly so intense as those proper to the antenna itself. Thus the manner of oscillation is essentially the same in the two methods, but the latter is more regular and powerful than the former. In the inductive method of excitation, on the other hand, the prominent feature of the oscillations is that one due to the condenser circuit. With antennas of different lengths, there is little change in this oscillation, the curve indicating it being decided and definite; but only one-quarter of its wave length is shown. This may be due to the great losses from radiation by the wire. The fundamental proper to the antenna is also present, but it is not nearly so intense as in either of the other two systems. The most effective length of the antenna, therefore, is one-quarter wave length, not a higher multiple. When inductance is inserted between the condenser circuit and the earth, the fundamental oscillation is not so regular or intense, other oscillations (overtones) being superposed. For the production of oscillations by the direct method a small capacity cannot satisfactorily balance the antenna; in the inductive method, however, a capacity acts like an earth connection or a similar wire.—*Am. Jour. Science*, January.

Measuring the Wave Length in Wireless Telegraphy.—Drude.—A communication in which he describes the following method of measuring the wave length which he has found to be quite exact, while the apparatus used is so simple that any one can make it himself. The principle is to adjust the secondary circuit so as to be in resonance with the primary circuit to be tested. The secondary circuit consists of a circular plate condenser (with air, petroleum or water as dielectrics, while glass is better avoided since its dielectric constant depends on the frequency), and the self-induction in the form of an exactly rectangular coil. The length of the rectangle may be varied by means of a sliding contact piece, the position of which is changed by hand. The position of this sliding contact is read off on a scale which is calibrated in wave lengths. As wave indicator he uses in the laboratory or in open air at night a vacuum tube containing sodium or during day time a small air-gap over the condenser plates.—*Elek. Zeit.*, January 7.

Manufacturing Plant.—A fully-illustrated description of the new workshops of the Société Alsacienne de Constructions Mecaniques in Belford for the manufacture of large dynamos. The power used is taken from a 200-kw central station. The intention is to drive each tool directly by an electric motor, and it has been decided to do so with any new tool which consumes not less than 1 to 1.5 kw, while the older tools have not been changed. Some special machine tools are described.—*L'Ind. Elec.*, December 25.

Metric System.—A note stating that the Parliament of New Zealand has authorized the Governor to adopt, beginning with January 1, 1906, the metric system of weights and measures, so that from this date this system will be the only one officially recognized in New Zealand.—*L'Ind. Elec.*, December 25.

Electrical Law.—Ball.—A comparison of the law of electric lighting in England and America. The subject is dealt with under the following heads: Interference with property and vested interests; responsibility for accidents; responsibility for nuisance; damage caused by escaping current; transmission of messages by electricity; relations between companies and local authorities.—*Traction and Transmission*, January.

Fuel Handling Machinery.—Dawson.—The first part of a profusely illustrated serial on this subject. Various American firms are mentioned as originators of special types of coal and ash handling machinery.—*Taction and Transmission*, January.

New Books.

The Gas Engine. By Frederick Remsen Hutton, E.M., Ph.D. New York: John Wiley & Sons. 483 pages, 243 illustrations. Price, $5.00.

This book is intended as a complement to the author's previous work on the "Mechanical Engineering of Power Plants," and thus to complete the discussion of the general subject of engineering as related to the liberation of heat energy by processes of combustion, and its transformation into mechanical form by some type of mechanism constituting a heat engine. The point of departure in the present work is the liberation of heat energy by some process of combustion involving an explosive gaseous mixture. Then follows a discussion of the cycle of operations which the heat medium undergoes in transforming the heat energy into mechanical work, taken in connection with the types of motor in which these transformations are effected. The succeeding chapters then open up the details of mechanically effecting the mixture of fuel and air, its ignition, and the control of fuel supply in correspondence with the external work. Following these matters of practical arrangement, an extended theoretical discussion is given of the various possible cycles of operation. The treatment of this topic is clear and full in scope and gives perhaps the most satisfactory and complete general exposition of the subject at present in print. Credit for this chapter is given by the author to Dr. Charles E. Gucke, who developed the subject matter as a student under the author's direction.

Some reference is also made to internal combustion engines with heating at constant pressure, and to the possibilities of developing practical types, either of the reciprocating or turbine variety. The book closes with an account of various experiments on explosive mixtures, with a historical summary of the development of practice in this field of engineering, and with a bibliography of most of the important literature of the subject. No attempt is made to enter upon the field of design of the gas engine as a machine. The author considers that this field has been already sufficiently covered, and that the space at his disposal might be better used by a discussion of the engine with reference rather to its thermal and general relations, as indicated above.

The preparation of the book as a whole displays industry in gathering together the materials from varied sources, together with skill and judgment in combining them so as to form a satisfactory and fairly adequate presentation of the subject. The book should go far toward answering a distinct want in our present engineering literature on this subject, and it will be an acceptable addition to the library of all those who are specially concerned with the latest phases of power plant engineering practice.

Crompton Potentiometer.

The Crompton form of potentiometer, shown in the accompanying illustration, has been largely adopted in English lighting and power stations as a standard for verifying apparatus of all kinds, and for measuring the output of the machines and stations. It also forms part of the equipment of many technical schools and laboratories.

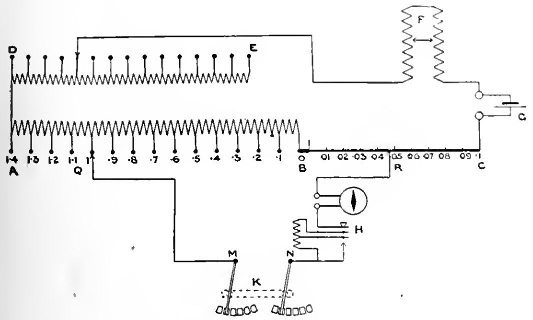

FIG. 1.—DIAGRAM SHOWING CONSTRUCTION OF INSTRUMENT.

The construction of the instrument is diagrammatically represented in Fig. 1.

The calibrated wire is arranged in 14 coils, called potentiometer coils, lettered *A B*, and a straight section, *B C*, called the scale wire, the resistances of the several coils and of the straight section being equal. One sliding contact, *Q*, moves over the terminals of the 14 coils, and another, *R*, along the straight wire. The reading of the instrument in the position shown is 1.046. The pairs of points whose potential differences are to be compared are connected to the blocks of the double pole switch, *K*, whose levers, *M N*, connect them, one pair at a time, to the sliding contacts, *Q R*, through the galvanometer. The galvanometer key, *H*, is arranged to complete the circuit through two resistances, which are short-circuited in succession as the key is depressed. The current required is derived from a small secondary battery, *G*. An adjustable resistance, consisting of a set of coils, *D E*, and a continuous rheostat, *F*, is placed in the circuit. By adjusting these the resistance of the circuit and the current passing through it from the storage cell, and consequently the fall of potential along the scale wire, can be continuously altered, and the operator is able to obtain a galvanometer balance against a standard cell when the reading of the sliders is that of the known e.m.f. of the cell at its actual temperature. If, for example, the temperature of the cell be 15°, so that its e.m.f. is 1.434 volt, the sliders may be set to that reading, and the galvanometer brought to zero by adjusting the resistance, *D E*, and the rheostat, *F*. When this has been done the scale readings at all points are direct readings in volts.

A view of the potentiometer is given in Fig. 2 and a diagram of its internal connections in Fig. 3. Here *a b* is the scale wire; *c* the set of equal potentiometer coils in series with it; *d* is the double pole switch connecting the 6 pairs of terminals, *A B C D E F*, in succession to the slide contacts; *e f* are the resistance coils and rheostat respectively, and *G* is the galvanometer key. All the moving contacts are under glass, and the coils and the scale wire are inside the box. The box itself is completely closed, but the inside can be inspected by removing a sliding bottom. Nearly all the measurements made involve the use of a standard cell, and one pair of terminals, the pair, *A*, is assigned to its connections to save confusion in working. Fuses of fine wire are inserted at all terminals except those for the galvanometer to save the instrument coils in the case of an accidental connection to a source of high pressure.

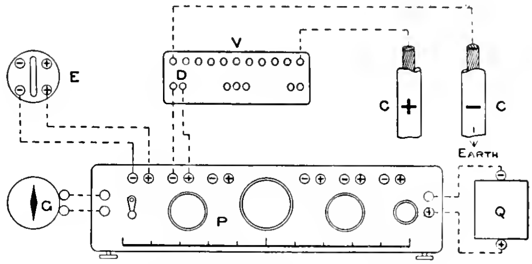

FIG. 4.—CONNECTIONS FOR TEST OF SUPPLY MAINS.

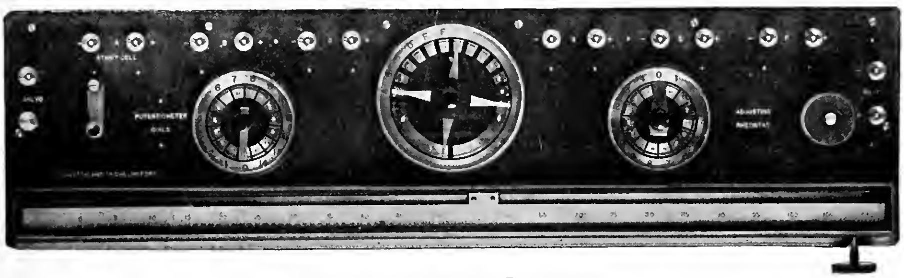

FIG. 2.—GENERAL VIEW OF POTENTIOMETER.

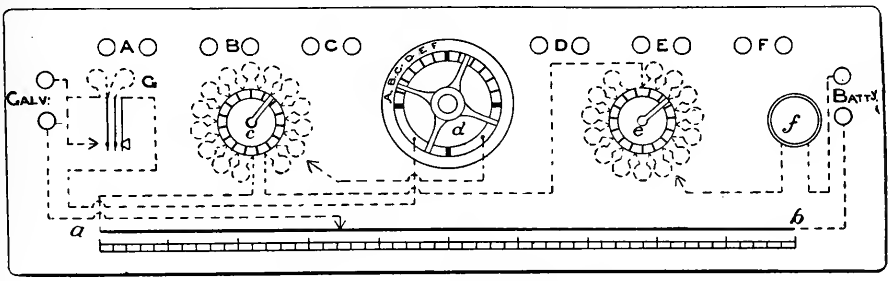

FIG. 3.—CONNECTIONS OF POTENTIOMETER.

Two scales are engraved for slide wire readings. One is a series of even divisions from 0 to 105, the resistance of the scale wire between 0 and 100 being the same as that of each potentiometer coil. It has been found convenient to be able to take readings a little beyond the 100 mark without having to move the potentiometer coil switch, and the scale is extended to 105 to admit of this. The other scale gives the values of the Clark cell at different temperatures, and is used in the following way: The potentiometer coil switch is set to 14, and the slide to the temperature of the Clark cell taken from the thermometer attached to it. The potentiometer reading is then the correct value in volts of the Clark cell at that temperature. By adjustment of the rheostat the galvanometer is balanced, and when this has been done the current in the potentiometer wire is such that readings at all points give correct values in volts, and the instrument is a direct-reading voltmeter. Its maximum range is then 1.5 volt, reading in thousandths of a volt, and by inspection to ten thousandths.

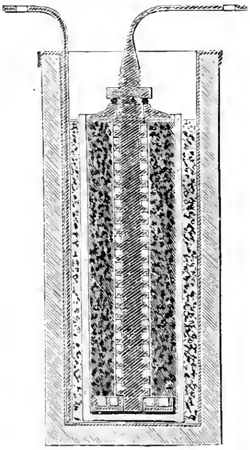
Volt boxes are employed consisting of sectional resistances. For example, a box designed to carry up to 1,500 volts consists of ten resistances in series, each of 10,000 ohms connections. Connections to various points of this resistance are made to terminals. Thus, between the terminals connected across 100 ohms, if the voltage applied is 1,500, the voltage across these terminals will be 1.5, a convenient quantity for comparison with the Clark cell.

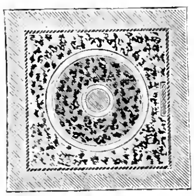
The accompanying diagram illustrates the application of the potentiometer to the measurement of the voltage of electric light mains. The volt box, *V*, is connected across the supply mains, *C* and *C*, and the one pair, *D*, of potential terminals is connected to the potentiometer, that pair being chosen which is nearest to zero potential. The difference of potential between the terminals, *D*, is compared with the e.m.f. of the Clark cell, *E*, and the voltage of the mains supply calculated from it.

A New English Storage Battery.

The illustrations herewith show a new type of storage battery, known as the N. S. storage, and being introduced by the N. S. Electric Storage Battery Company, Limited, 139 Queen Victoria Street, London, England. The inventor is Mr. J. T. Niblett, well known as the author of a treatise on storage batteries. While certain of the principles in the battery are not entirely new, yet there are a number of novelties in it and Mr. Niblett has arranged his active material in a way different from anything that has been previously done. The cell is of the porous pot type, a section of which is represented in Figs. 1 and 2, one showing a vertical section and the other showing a horizontal section. While this is the leading type manufactured, for the purpose of suiting other demands, the company also manufactures forms more suitable for other purposes, such as those illustrated in Figs. 3 and 4.

The active material consists of pellets or small cylinders, about 5/16 in. in diameter and the same length. These are made by compression in die plates, and when dry are exceedingly hard; at the same time they are very porous, and will absorb a considerable amount of the electrolyte. The

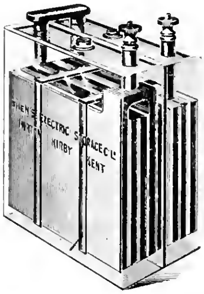


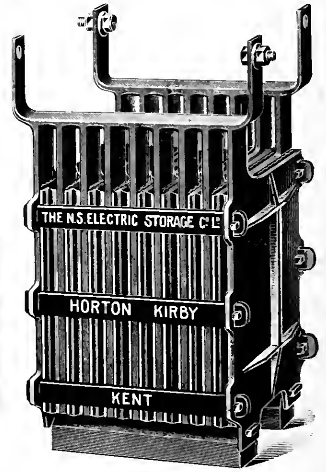


FIGS. 1 AND 2.—VERTICAL AND HORIZONTAL SECTIONS OF CELL.

pellets are packed in a porous pot round the positive electrode, of the form shown in the figure, while the space between the pot and the lead containing box (the negative electrode) is packed with disintegrated lead. A wooden case surrounds the whole. One of the advantages claimed for these cells is that, should the electrolyte escape by any means, it would not stop the discharge, as such a large quantity of solution is absorbed in the pores of the active material and the separator, that it allows action to go on for some considerable time. Cells have been emptied and then discharged at the normal rate, and have given half their normal capacity under these conditions.

Three distinct types of cell are made. The solid, which is more suitable for large electric lighting installations, central stations and tramway work, is considered the best, as in its present form it can be supplied at low rates, and it has the advantage that short-circuiting has practically no injurious effect. Owing to the large amount of exposed active material on both the positive and negative sides, very high rates of charge and discharge may be taken from the cell without in any way injuring it. It is stated that even if excessive rates of discharge were taken from the elements, so as to cause slight expansion and disintegration, this would do no harm, as the material would tend to settle at the bottom of the cell, and would, in time, solidify and become active, so that no loss in capacity of the cell would occur.





FIGS. 3 AND 4.—TWO FORMS OF N. S. STORAGE CELL.

The second type is termed the semi-solid accumulator. This is built up of special grids, which are thick, and contain a large amount of active material. This material is of the same composition as that used in the solid cells, and, being highly porous, may be used in thick masses. In this case ribbed porous plates are employed for the separators, and the elements are held together by stout clamping plates, which really constitute the outside negatives of the sets of elements. These clamping plates are pressed together by connecting bars having a flange at one end and an india rubber pad pressing against this, so as to allow for expansion and contraction during the charging and discharging operations. These cells are used for low-capacity batteries, and in cases where a small and light battery is required, also for motor-car driving.

The third type of cell is termed the portable type. These are supplied made up into batteries ranging from two to six cells for medical purposes, carriage lighting, X-ray work, actuating small electromotors, and for ignition purposes for petrol engines and motor cars. In constructing these cells, which are also of a semi-solid type, the first consideration has been durability, and the elements are of a very robust character, well calculated to withstand the jerking and jarring which they may receive when on vehicles or when being carried about. The elements are mounted in vulcanite or celluloid cases, enclosed in a hard-wood containing box, and are fitted either with two terminals, or with terminals to each cell as required.

The makers state that the cells behave much in the same way as the ordinary form of accumulator. The electrical pressure of the cells immediately after charging is about 2.2 volts, but this quickly sinks to the normal 2 volts. On the discharge the fall of potential is proportional to the rate of discharge, but to discharge down to 1.7 volts for a lighting circuit is quite permissible, and in the case of tramway and power circuits they may be discharged down to as low as 1 volt per cell. This apparently does not injure them in any way.

As much as 95 per cent. quantity efficiency and from 70 to 75 per cent. energy efficiency has been obtained with both the solid and the semi-solid types of cell. The capacity per pound of complete cell, in the case of the solid batteries, is about 4 watt-hours. In the case of the smaller cells it may be somewhat less, but as the capacity of the cell increases, the capacity per pound of complete cell tends to increase, a condition not usually met with. In the case of the semi-solid cells, about 10 watt-hours per pound of complete cell are obtained, but this, of course, is regulated by the nature of the containing boxes, whether they are of vulcanite, glass or lead-lined wood. With the small portable batteries, capacities have been obtained up to 12 watt-hours per pound of complete cell.

A solid cell made up some 15 months ago was taken out of a battery, discharged, and then emptied, and was allowed to stand idle for a matter of four months. At the expiration of this time the cell was filled up with electrolyte, and put on charge, and after one or two charges and discharges it was found to be in perfect condition.

The cells have been frequently short-circuited, but no detrimental effect seems to occur; they have also been run down until they showed absolutely no pressure whatever, and on the re-charge they appeared to come up quite well. This is believed to be due to the fact that the elements have an enormous amount of exposed surface, and the active material cannot disintegrate or leave the conductor. The simple construction of the "solid" cell, rendering skilled labor superfluous, both in manufacture and in working, is one of its most prominent features.

The Allis-Chalmers Nurnberg Gas Engine.

It is but a few years ago that the engineering fraternity in general looked askance at gas engines of even 150 hp, and the field was generally slighted. It was not until the industrial conditions in Europe rendered it absolutely essential to reduce the cost of power production to a minimum, when, aided by a more thorough comprehension of the action of such engines, the modern large gas engine came into being and was installed and operated with such success in Europe, that it has already been accepted as a staple.

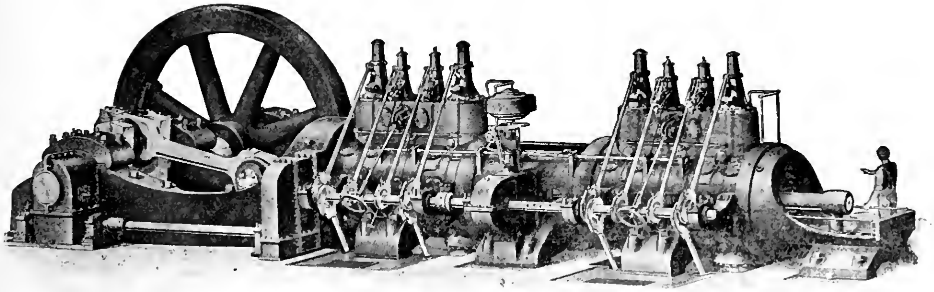
Realizing the vast importance of these developments and in the consistent pursuit of its traditional ambition to remain in the van of American builders of power generators, the Allis-Chalmers Company spent considerable time and utilized the best talent in the thorough investigation of gas engines of high power, with the result that it has acquired sole rights for, and is now building in the Edward P. Allis Works at Milwaukee, the Nürnberg gas engine illustrated herewith. This engine is built in units ranging from 130 to 6,000 brake hp to operate with all classes of gaseous fuel, and is adapted to all work that can be performed by a stationary steam engine, including the driving of alternating-current generators for light and power purposes. The Nürnberg gas engine is of the four-cycle system and double-acting type; it embodies the latest improvements which make for reliability, efficiency and permanency; and its builders give the most stringent guarantee in reference thereto.

A glance at the cut will indicate a few of the main features in which the Nürnberg gas engine is a striking improvement upon the familiar gas engine of the last decade. It is double-acting, like a modern steam engine, and will, therefore, develop the same power with a cylinder of one-half the cubic contents required by the older type, while an equal number of Nürnberg cylinders will give the crank shaft a double number of impulses. In its standard construction, with two cylinders placed in tandem and a single set of transmitting parts, the engine utilizes these parts to their full extent, instead of to the extent of only 25 per cent., as is the case in the ordinary single cylinder, single-acting gas engine: and the Nürnberg gas engine accomplishes this without increasing the maximum stresses to which the moving parts are subjected. The valves are operated by means of eccentrics in place of the noisy and short-lived, old-time cams. The pistons are positively supported by outside cross heads running on cool slides, so that the cylinder walls are not called upon to bear any weight, whereby their efficient lubrication and permanent tightness are assured. The inlet and governing valves and their gearing are readily accessible and always in sight, while the exhaust valves are located at the lowest point of the cylinder, to insure the expulsion of such solid matter as may be carried into the cylinder by the gas, or result from carbonization of the lubricant. The cylinder heads can be removed and replaced without the disconnection or deranging of any part of the valve gearing, and, likewise, the pistons may be withdrawn from their cylinders examined, and fitted with new rings, without disturbing any valve mechanism, or even the metallic packing of the piston rods. In a similar manner access to the inside of the cylinder and valve chambers is rendered easy and quick. All parts of one cylinder are interchangeable with any corresponding parts of all other cylinders of the engine.

The regulation is most effective and simple. It is attained by the use of an ordinary high-grade, fly-ball governor, and by a novel construction which combines close regulation with high efficiency under light loads; the whole effect being very similar to that of a modern steam engine.

The crank shaft is journaled in bearings of special construction, giving firm support without undesirable rigidity. Great care has been exercised to allow all parts of the engine full freedom to expand and contract without endangering its perfect alignment. Unusually extensive and carefully distributed water-cooling is provided for, and all important moving parts are automatically lubricated under pressure, for which purpose special oil pumps are furnished.

The Nürnberg gas engine is not in any sense of the term an experiment, for it has been thoroughly developed, perfected and proved by its original designers and builders in Germany. Its introduction into this country by a manufacturing establishment of the high standing earned and enjoyed by Allis-Chalmers Company is a sufficient guarantee of its design and construction.



Nürnberg Gas Engine.

Blind Telephone Operator.

It is stated that Mrs. Post, of North English, Ia., who is totally blind, successfully manages the local telephone exchange with over 300 subscribers. Each line is provided with a special bell of a special tone, and those bells are all mounted in a cabinet a few feet from the switchboard. There are large bells, small bells, wire clock gongs, sleigh bells and high-keyed bicycle bells. A fine bit of steel wire four inches long is soldered to each bell hammer, and a square sheet of paper attached to this wire bears the line, name and number, forming a visual signal for the assistant operator, who can see. The bell cabinet is so situated that the paper squares may be plainly seen from the operator's seat. Mrs. Post is able to distinguish not only each one of the forty-five bells by its peculiar tone, but also the voices of hundreds of men, women and children whom she serves. She is a graduate of Iowa College for the Blind, and was noted at that institution for quick and retentive memory. We ought to hear next of a deaf telephone operator—in an automatic exchange.

The Heany Arc Lamp.

Since the Heany arc lamp was described in these pages just about a year ago, a number of changes and improvements have been made in it, which are worthy of note. To begin with, it may be mentioned that the supporting stays are made of 3/8-in. tubing instead of 5/32-in. rods. The lamp has been provided with a top casting, on which is mounted a substantial switch and binding posts. The binding posts are mounted on porcelain, and have — and + signs plainly visible. They have also large binding screws and wire holes large enough to accommodate No. 6 wire. The resistance wire is wound on a porcelain ring which surrounds the supporting tubes; the porcelain ring is cut with a thread of 10 pitch, and the wire is wound in this thread. A novel vice-like clamp slides in a slot in the porcelain ring to cut in or out the resistance wire for various line voltages. The solenoid spool is held on the supporting tubes by six strap clamps, instead of screws, as in the old lamp.

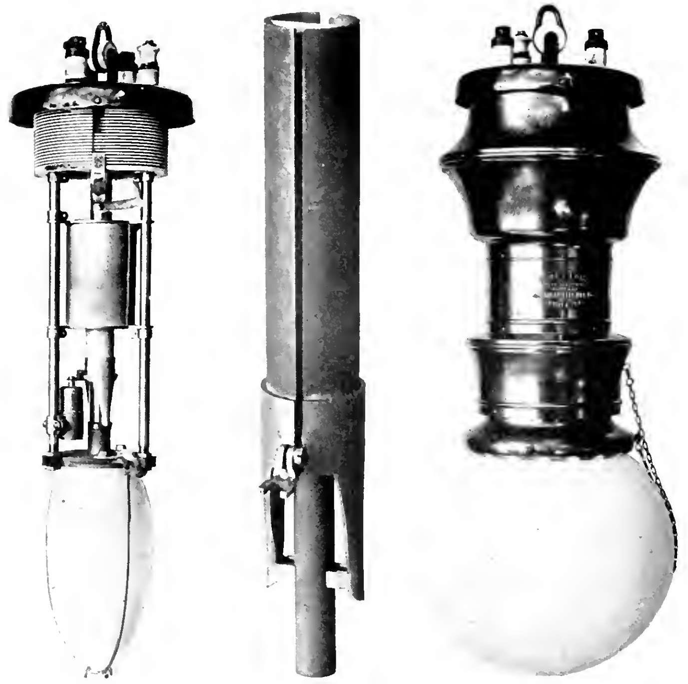
The dash-pot in the earlier lamp was made of drawn tubing, the new is cast and reamed, increased from 1/2-in. to 5/8-in., and is fastened to one of the supporting tubes with a clamp, the supporting tube being provided with a locating pin, which brings the dash-pot to the proper place. In the old lamp no provision was made for locating the dash-pot, and in the hands of inexperienced persons might have caused trouble. In the new lamp any one can place the dash-pot in position. The clutch is made entirely of stampings, instead of castings.

The carbon receiving tube has been increased in diameter from 5/8-in. to 3/4-in., so that 1/2-in. carbon may be used if desired, and to interchange with the other types of Heany lamps. In fact, in improving the lamp this point has been carefully considered, and the casing, carbon receiving tube, supporting tubes, globes and all principal parts will interchange on all the types.

The casings are made of solid copper, and well ventilated, as well as weather-proof. The lower carbon holder has been provided with a cam to lock the carbon, instead of a screw, and has a projection which limits the weight of carbon and is of importance in trimming. The spider on base of the old lamp has been dispensed with and a projection from the base of the lamp takes its place.

In the old lamp the carbon was exposed partially; in the new lamp this space is closed, making a bearing for the carbon, and preventing admission of oxygen to the inner globe, prolonging life of carbons, and at the same time simplifying the construction.

The internal parts are copper and nickel-plated to prevent corrosion and oxidation. Mica and porcelain are used throughout as insulation.



FIGS. 1, 2 AND 3.—ARC LAMP.

Telephone "Express" Switchboard.

The International Telephone Manufacturing Company of Chicago has produced a mechanical self-restoring drop or "express" type telephone switchboard claimed to embody in its construction many new and important features. The new board is made up in any capacity, ranging from the small village sizes to those of one thousand lines, the larger equipments being provided with the necessary trunking, or transfer, systems, which may consist of the common method of equipping the various sections with trunking jacks and order-wire keys, or the more elaborate equipment of flash lights, trunking cords, etc. Each operator's position, or section of cabinet, is provided with either one hundred, one hundred and fifty or two hundred lines. Fig. 1 shows the board equipped for one hundred and fifty lines divided into three panels of fifty lines each.

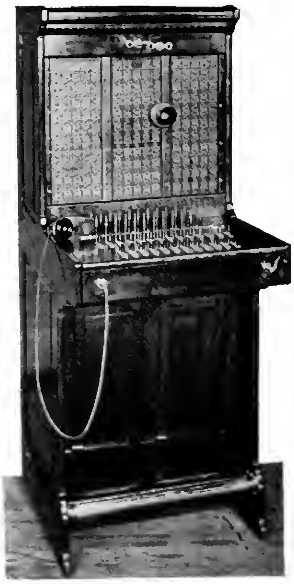


FIG. 1.—"EXPRESS" SWITCHBOARD.

The entire equipment is mounted in a highly polished quarter-sawed golden oak cabinet with five-ply hinged key shelf, hinged double panel back, and with a substantial brass foot-rail. On the hinged shelf are mounted the well-known "International" keys having all the terminals at one end, thus making it possible to contain all of the wiring in one key cable and leaving all of the springs and contact points easy of access and inspection. The plug board is covered by heavy belt leather stained to match the wood-work. In the front of the board and immediately under the key shelf are mounted the necessary night alarm and power generator switches, which are of the locking plunger type with the buttons almost flush with the woodwork. The hand generator is mounted in the back of the cabinet on a substantial shelf which serves the triple purpose of a mounting for the generator, the cord terminals and that of adding strength and rigidity to the frame.

The combined drops and jacks are mounted in strips of five on strong steel plates, as shown in Fig. 2. These supporting strips in turn are securely fastened to a well-constructed steel frame by means of heavy machine screws which are covered by wooden stile strips stained and finished to match the cabinet.

A side view of the drop and jack is shown in Fig. 3. The drop shutter is mounted on the front of the steel mounting plate and the back plate of the shutter has part of the stock formed out at the bottom to provide a positive stop for the shutter to prevent its falling far enough to cover the jack.

FIG. 2.—STRIP OF DROPS AND JACKS.

The drop is of the non-inductive tubular type and is mounted on the base of the jack by means of two screws. The jack springs are of the best grade of German silver and are made of very heavy stock. Near the front they are brought strongly against an insulated stop pin which makes it possible to give them a heavy tension in their normal position and insures a positive plug contact at all times with but the slightest displacement, or bending, of the springs. The jack springs are mounted on the brass cast base and are firmly clamped by heavy machine screws and properly formed washers. The insulation is of mica. The combined drop and jack are mounted on the steel strip by the use of a threaded jack ferrule which passes through the strip from the front of the board into the end piece of the brass jack base. This form of insulation makes it possible to remove any one of the drops and jacks from the front of the board in the smallest fraction of a minute and without disturbing the drop shutters or any other line equipment. A small friction wrench which fits firmly into the jack ferrule is used for this purpose. The tubular drop covering or shell is provided with a guide pin, thus making it impossible to place the coil in any other than its proper position.

The drops and jacks are perfectly insulated from the frame and the mounting strip by a heavy mica sheet and with hard rubber bushings for the jack ferrules and binding screws. This method assembling and construction absolutely prevents cross talk and other inductive troubles. The shutter restoring trigger is also mounted on the base of the jack by means of a heavy German silver compensating spring, the peculiar construction of which makes it absolutely impossible for the drop to ever fail to restore. The night bell spring is mounted immediately above the restoring trigger and is brought into connection with the night bell contact by the falling of the drop and the consequent raising of the trigger. The night bell contacts for each bank of five drops are made of one solid brass strip which leads out to the end of the mounting strip where connection is made by a small spiral spring to the common night bellstrip which is placed in the rear of the board in an accessible position between the drop panels or immediately back of the stile strips. It is provided with small hooks so that the night bell circuit of each bank of five drops may be easily disconnected for testing.

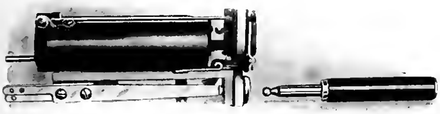

FIG. 3.—DROP AND JACK.

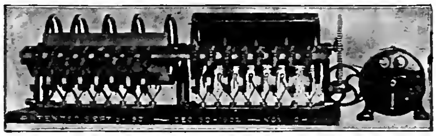
The boards are wired full metallic throughout and for their full capacity. They are provided with sufficient cable to reach the lightning arrester or distributing rack. The cables may be either permanently soldered to the line equipments or to clips, in which latter event connection is made by means of screws and washers. Each part of the apparatus is constructed with special tools and dies so that all like parts are exactly uniform in size, shape and form. This makes it possible to assemble the complete equipment without in any way altering or filing any of the parts and insuring accuracy and permanency of adjustment.

Improvements in Sign Flashers.

It is frequently the case that electrical apparatus has to go through a considerable evolution before being reduced to its simplest form. This seems to have been the case with sign flashers. An improvement in the direction of simplicity and more satisfactory operation has recently been made in the design of the electric sign flashers made by the Reynolds Electric Flasher Manufacturing Company, of Chicago. As flashers were formerly made, each make-and-break switch was operated by a cam or segment bolted to a wheel. There were as many of these wheels with cams as there were make-and-break switches on the flasher.

The new design does away with these cams and substitutes a segment of a sheet steel cylinder, which is notched or slotted so as to give the proper combination. This construction is especially an advantage where a number of circuits are to be flashed simultaneously. With the cams it was found difficult to adjust them so

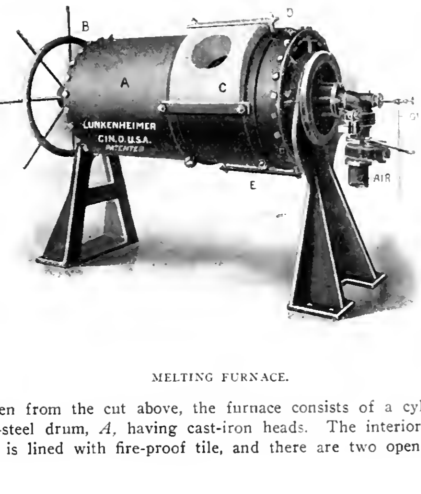


SIGN FLASHER.

they would snap all the switches at exactly the same instant, and the result was a ragged effect on the sign. With the sheet steel it is simply necessary to provide a straight edge in order to have the switches operate simultaneously. If they are not to be operated simultaneously, the edge is notched. The accompanying illustration shows a flasher which is adapted to flash two views of a sign alternately, the circuits on each half being all lighted and extinguished at the same instant. Another advantage of this construction is that there need not be a wheel on the shaft for each switch. It is only necessary to have enough wheels to support the stiff sheet steel segment.

Metal Melting Furnace.

We illustrate herewith the Lunkenheimer metal melting furnace, which has been found to afford a very efficient and economical method of melting metals, particularly brasses and bronzes. As will



MELTING FURNACE.

be seen from the cut above, the furnace consists of a cylindrical sheet-steel drum, *A*, having cast-iron heads. The interior of the drum is lined with fire-proof tile, and there are two openings on opposite sides of the drum. Only one of these openings is in use, the other being closed by a fire clay filling. The object of having two openings is to increase the life of the linings of the furnace. It has been found that the furnace wears out quicker around the filling hole (which also serves as outlet for the flame) than elsewhere. The advantage is that, when one filling hole is worn out this can be closed by a fire clay filling and plate, the furnace reversed and the other hole cut out and put in service.

The oil burner is of a special type, designed to give the greatest amount of heat with a minimum consumption of oil. In the Lunkenheimer foundry there are ten of these furnaces in use, and they are able to secure from six to seven heats per working day of ten hours from each furnace. The weight of each heat will average about five hundred and fifty pounds, and the oil consumption varies from two to two and one-half gallons of crude oil per hundred pounds of metal melted. The life of the linings is from three to four hundred heats, this varying with the kind of metal melted.

This furnace is made in two sizes, the No. 1 size having a capacity of five hundred and fifty pounds of metal per heat, and the No. 2 size having a capacity of twelve hundred pounds of metal per heat.

Steel Frame Generators and Motors.

Some excellent apparatus has been produced by the Triumph Electric Company, of Cincinnati, Ohio, and we are now able to illustrate and describe their latest types of steel frame bipolar motors and generators, made as motors in sizes from ½ to 5 hp, inclusive, and as generators from ½ to 5 kw, inclusive.

The crown and pole pieces are made of soft close-grained steel. The poles are accurately fitted and bolted to the crown and are readily removable in case of necessity. Cast-iron yokes, heavily ribbed, are centered against the sides of the crown, and are held firmly in position with bolts. These yokes, by removing the bolts, can easily be rotated, thereby adjusting the machine for wall or ceiling suspension, the oil well always remaining in the proper position. The bearings are of gun metal, of the self-oiling type, and are interchangeable. When desired, end plates are furnished, completely enclosing all of the working parts.

The armature core is built up of thin sheet discs and is mounted on a shaft made of the best hammered steel. These discs are notched, and when mounted on the shaft these notches form slots on the circumference of the core, in which the armature conductors are imbedded. The discs are annealed after punching, and in addition to this are varnished before being assembled on the shaft. The armature conductors are thoroughly insulated from the core, every precaution being taken to protect them from injury. The commutator segments are of pure drop-forged copper and are insulated from each other and from the shell with the very best mica. The commutator shell is so constructed that it is impossible for a segment to become loose and cause trouble, and has wells to prevent the oil from getting under the segments.

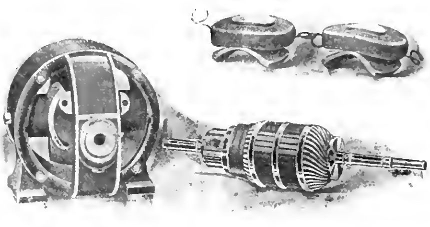


FIG. 1.—ELEMENTAL PARTS OF MOTOR.

The field coils are form-wound and thoroughly insulated. Every coil is soaked in a varnish bath, then baked, after which it is covered with two layers of friction tape, finally receiving two coats of insulating paint.

The brush holders are of the very simplest and most effective design, and of the lightest possible construction consistent with necessary strength and durability. The brushes are of carbon and are fastened rigidly at the end of the holder. As there is no sliding friction of the brush in the holder, the spring has but little weight to move, so that the tension is very light; this results in a very quick and sensitive adjustment of the brush, which eliminates sparking and heating and wearing of the commutator. The holder is clamped to the stud and is provided with a simple and ready means for adjustment if that is ever required. The brushes are properly set in the factory and should not require adjusting under any condition of load, or overload.

The machines are rated well within their limits of capacity, and, as open machines, no part will heat more than 40° C. above the surrounding air, when operated for ten hours under full load. They will withstand an overload of 50 per cent. for a period of one hour, and a momentary overload of 100 per cent. without injury. As entirely enclosed machines the ratings will be somewhat less, to meet these requirements.

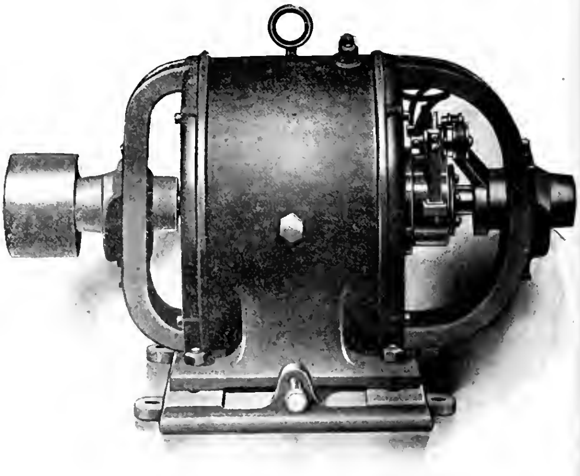

FIG. 2.—STEEL GENERATOR AND MOTOR.

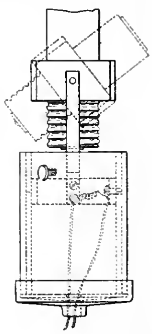
Attaching Plug and Socket.

A patent was recently allowed to Mr. W. H. Kelsey, of the Electric Building, Cleveland, on an attaching plug and lamp socket, herewith illustrated. When this device is made as an electric attaching plug, and the reversing ends contain an Edison or Thomson-Houston plug contact, with electric connections to the supporting arms within the holder, then, by the simple turning or reversing of the ends of the double plug, either the Edison or the Thomson-Houston plug end is presented for attaching to its proper socket. Another feature this device has is the avoidance of twisting the attaching cord. This is avoided by manipulating this plug as follows: Remove the double plug from the holding arms to which are attached the conducting wires, then screw this detached double plug part into the corresponding socket, Edison or Thomson-Houston, then raise the holder in which are the connecting arms with cord attached thereto, and snap these arms tightly to the side contacts on the plug, and the cord remains in its undisturbed state without kinks or twists. Various styles of plugs are made to fit any kind of a single or double-pole socket.



PLUG AND SOCKET.

When this device is made as a lamp socket, the removable reversible part contains two sockets, an Edison and a Thomson-Houston, one on each end, either of which may be turned outward, as is the case with the plugs above described. Therefore, either lamp may be used in this double socket. In addition to this feature of reversibility the device can be made to hold these lamps either one at a time, or both at the same time, and in multiple or in series, by simply placing them across the opening of the holder. Hence, if desired, two lamps can be burned at the same time, or one lamp and an electric fan, or electric stove, or any two such devices can be placed in multiple or in series with each other.

NEWS OF THE WEEK.

Financial Intelligence.

THE WEEK IN WALL STREET.—Quotations closed steady after an irregular reaction due to less favorable Eastern news and profit-taking by professional traders. The manipulative and artificial character of the recent advance and the limited nature of the outside buying have had an effect, while adverse reports on iron and steel trade conditions also influenced the trading. The latter led to a renewal of pressure in the United States Steel securities toward the end of the week, when foreign houses were considrable sellers, both of the preferred shares and the new 5 per cent. bonds. In the electrics and tractions the gains that were recorded last week were largely lost. There was little business done in these securities. Brooklyn Rapid Transit closed at the lowest quotation of the week, namely, 47⅛, this being a net loss of 3⅛ points. Metropolitan Street Railway lost 2 points, closing also at the week's lowest figure—121—the sales aggregating 6,000 shares. General Electric lost practically all of its gain of the week previous, closing at 170⅛, a net loss of 7⅝ points; and Westinghouse common closed at 167, a loss of 5 points. The extreme quotations of this stock were 166½, the lowest, and 173, the highest. Western Union closed at 88½ and was steady throughout the week. American Telephone & Telegraph closed at 128, this being a net loss of ⅛ point and the lowest price of the week. Following are the closing quotations of February 2:

TROLLEY IN TEXAS.—Conversion of the Gulf & Interstate Railroad into an electric line and the consolidation of two other electric lines, all three under one control, is reported to have been practically accomplished by John W. Gates and his associates. It is said that the new company has practically consummated a deal whereby it will take the Gulf & Interstate, which is the short line between Galveston and Beaumont. At Beaumont this road will connect with the Beaumont & Sour Lake electric line and later join the projected Port Arthur & Beaumont electric line, of which Gates is the founder. Gates is largely interested at Port Arthur and in the oil fields, and the Port Arthur road will be started within a few weeks. The Gulf & Interstate runs through a productive territory, and is 74 miles long. With the three lines consolidated, the electric system would traverse the oil, lumber and rice section of East Texas with a Gulf outlet at Galveston and Port Arthur. It is also stated that another electric line is projected from Beaumont, which will be the center of the system, northeast to the Jasper gold field. It is said that the project will involve nearly $2,000,000.

CHICAGO TELEPHONE.—The Chicago (Bell) Telephone Company reports as follows for the year ended December 31, 1903:

	1903.	1902.	1901.	1906.
Gross	$5,534,590	$4,570,806	$3,775,002	$3,129,238
Expenses	4,113,246	3,368,335	2,691,129	2,258,780
Net	$1,421,344	$1,202,471	$1,083,873	$870,458
Dividends paid	1,274,835	1,075,193	960,000	749,808
Surplus	$146,509	$127,278	$123,873	$120,650
Cash on hand	547,640	134,706	....	....

Assets of the company show an increase of $2,348,475, making a total of $15,251,354. During the year $1,428,320 was invested in a new plant. There was an increase of $2,007,000 in stock issue. The report is considered excellent. No changes were made in the directorate. The Chicago Telephone officials say the earnings from extensions easily guarantee the regular dividends on the new stock issue, which will be at par as usual.

DETROIT TROLLEYS ANNUAL REPORT.—The Detroit United Railway system reports as follows for the year ended December 31, 1903:

	1903.	1902.	1901.	1900.
Gross	$4,386,975	$3,961,403	$2,919,171	$2,575,276
Ex. and tax.	2,613,977	2,260,786	1,596,765	1,439,057
Net	$1,772,998	$1,700,617	$1,322,406	$1,136,219
Other income	38,863	31,247	23,067	14,559
Total income	$1,811,861	$1,731,864	$1,345,473	$1,150,778
Charges	1,000,000	948,902	675,344	638,317
Surplus	$811,861	$782,952	$670,129	$512,461
Dividends	500,000	500,000	500,000	....
Surplus	$311,861	$282,952	$170,129	$512,461

The above includes Detroit United Railway, Rapid Railway System and Sandwich, Windsor & Amherstburg Railway. Over $1,200,000 was spent on betterments for the entire system during the year. The system carried 104,018,886 passengers, the average receipts being $0.358 per passenger. The car mileage made was 19,114,970 miles.

BROCKTON LIGHTING ANNUAL.—The annual report of the Edison Electric Illuminating Company, of Brockton, Mass., shows as follows:

	Nov. 30, '03.	Nov. 30, '02.	Increase.
Gross earnings	$104,967.24	$95,044.93	$9,922.31
Operating expenses	71,721.15	61,567.86	10,153.29
Net earnings	$33,246.09	$33,477.07	*$230.98
Fixed charges	11,347.82	8,920.88	2,426.94
Net profit	$21,898.27	$24,556.19	*$2,657.92

* Decrease.

LOWELL ELECTRIC LIGHT REPORT.—The annual report of the Lowell (Mass.) Electric Light Corporation shows as follows:

	Nov. 30, '03.	Nov. 30, '02.	Increase.
Gross earnings	$230,854.72	$207,298.26	$23,556.46
Operating expenses	153,128.27	130,177.31	22,950.96
Net earnings	$77,726.45	$77,120.95	$605.50
Fixed charges	12,724.43	13,587.33	*862.90
Net profit	$65,002.02	$63,533.62	$1,468.40

* Decrease.

MINNEAPOLIS LIGHTING ANNUAL.—The Minneapolis General Electric Company reports as follows for the past year:

	Nov. 30, '03.	Nov. 30, '02.	Increase.
Gross earnings	$551,711.29	$496,122.03	$55,589.26
Operating expenses	308,832.96	257,311.66	51,521.30
Net earnings	$242,878.33	$238,810.37	$4,067.96
Fixed charges	110,021.52	97,803.92	12,217.60
Net profit	$132,856.81	$141,006.45	*$8,149.64

* Decrease.

DIVIDENDS.—The New England Telephone & Telegraph Company has declared its regular quarterly dividend of 1½ per cent. to stock of record January 30. Books close February 1 to February 13, inclusive. The North American Company has declared a 5 per cent. dividend, payable in quarterly instalments. This is an increase of 1 per cent.

NEW YORK AND NEW JERSEY TELEPHONE COMPANY.—The directors of the New York & New Jersey Telephone Company have voted to offer at par to the stockholders $1,252,000 of the unissued stock of the company. The offer will be in proportion of one share for each ten shares held, and expires on March 1.

AMERICAN DISTRICT TELEGRAPH.—The American District Telegraph Company, of New York, reports as follows for the year ended December 31, 1903:

	1903.	1902.	1901.	1900.
Revenue all sources	$577,676	$610,043	$624,194	$590,536
*Operating expenses	511,808	513,176	535,544	503,690
Net	$65,868	$96,867	$88,650	$86,846
Dividends	76,888	76,886	96,107	86,497
Deficit	$11,020	Sur.$19,981	$7,457	Sur.$349
Miles wire	1,552	1,552	1,548	1,537
Offices	85	85	85	86
Instruments	29,143	27,940	27,905	27,943

*Includes construction expense.

The general balance sheet as of December 31, 1903, compares as follows:

Assets:	1903.	1902.
Plants, patents, stocks merged, etc.	$4,052,997	$4,018,865
Stocks and bonds, companies not merged	207,540	235,700
Supplies and uniforms	34,204	21,413
Sundry accounts receivable	58,884	46,487
Advances	90	746
Due from managers	7,669	22,241
Due from agents	1,234	2,023
Cash	21,778	18,725
Total	$4,384,397	$4,366,200
Liabilities:		
Capital stock	$3,844,700	$3,844,700
Sundry accounts payable	27,239	7,260
Contingent liabilities	8,830	5,940
Profit and loss surplus	503,628	508,300
Total	$4,384,397	$4,366,200

President Robert C. Clowry says in part: "The revenues of the company were effected by the distinctly unfavorable local conditions which prevailed throughout the year. The loss is largely in earnings from messenger service and has as far as possible been offset by reductions in the expenses, aggregating $22,025. The work of improving the company's plant has been steadily pursued. This work, together with the cost of wiring new buildings connecting new subscribers, fitting up new offices, etc., amounting in all to $34,508, has been paid out of current earnings and surplus."

MICHIGAN STATE TELEPHONE.—The Michigan State Telephone Company has filed articles of incorporation in Michigan with a capital stock, all paid in, of $25,000, par $100, divided into $10,000 6 per cent. cumulative preferred and $15,000 common. The right is reserved to increase the capital stock. The voting powers of the common and preferred are equal. The incorporators and directors are: William A. Jackson, founder of the Michigan Telephone Company, who will probably be president of the new company; John T. Shaw (vice-president), cashier of the First National Bank; James Cullen and Elliott G. Stevenson, partner of Don M. Dickinson, counsel for the bondholders of the Michigan Telephone Company here. This is a preliminary step to the reorganization of the Michigan Telephone Company. Much Detroit capital is believed to be going into the new concern. When the regular company is organized the present new company will be dissolved. The minority interests in Michigan Telephone have not yet filed an appeal. They say they may, but it is believed they will not. This step indicates progress on the part of the bondholders.

NORTH AMERICAN DIVIDEND.—A dividend of 5 per cent. for the year was declared last week by the directors of the North American Company, this dividend representing an increase of 1 per cent. over that paid during the past year. That such action would be taken had long been predicted in Wall Street, where for some time it had been said that the earnings jusified a larger distribution upon the company's stock. In connection with the increased dividend it is explained that the policy of the company is to declare dividends out of its fixed income derived from interest and dividends receive from its investments, while earnings from other sources are employed to increase the company's surplus or for the development of the company's light and power properties. The present capitalization of the North American Company is $17,000,000, to which amount it was last year increased from $12,000,000. In 1901 the capital stock had been reduced from $40,000,000 to $12,000,000. The dividend declared is payable in four quarterly installments of 1¼ per cent. each, beginning March 1.

STANDARD UNDERGROUND CABLE.—The annual report of the Standard Underground Cable Company shows gross business for 1903 of $9,192,618, and net earnings of $704,438, or about 35 per cent. on the company's $2,000,000 capital. Dividends amounting to 12 per cent. were paid, leaving $474,706 to add to surplus, which now amounts to $1,229,112. The company's business for 1903 was more than double that of 1902. The company has no outstanding notes, mortgages, bonds or preferred stock, and no contingent liabilities on business paper of customers. The mills of the company handled during 1903 copper equal to 5 per cent. of the total production of copper of the entire North American continent for that period. On December 31, 1903, the company had unfilled orders amounting to over $1,000,000, and orders have been booked since that date amounting to over $600,000.

SOUTHERN NEW ENGLAND TELEPHONE.—The Southern New England Telephone Company reports for the year ended December 31, 1903, as follows:

	1903.	1902.	Changes.
Gross	$1,098,289	$919,556	Inc. $178,733
Expenses	897,226	746,812	Inc. 150,414
Net	$201,063	$172,744	Inc. $28,319
Dividends	187,050	172,500	Inc. 14,550
Surplus	$14,013	$244	Inc. $13,769

At the annual meeting of the stockholders the retiring board of directors was re-elected. The increase in the amount of business during the year was the greatest in the company's history. Of the capital stock of $3,500,000, the American Telegraph & Telephone Company owns $955,400.

SOUTH SIDE ELEVATED.—The South Side Elevated, of Chicago, reports as follows for the year ended December 31, 1903:

	1903.	1902.	1901.	1900.
Gross	$1,679,310	$1,483,843	$1,362,231	$1,286,638
Expenses and taxes	994,376	862,338	844,960	748,482
Net	$684,934	$621,505	$517,271	$538,236
Interest and dividends	442,883	442,874	391,705	340,515
Surplus	$242,051	$178,631	$125,566	$197,721

President Carter, in his annual report, outlined the plan to issue $7,000,000 new stock to stockholders at about 93, payable in three equal quarterly installments, viz.: April 30, 1904; April 30, 1905, and April 30, 1906. The stock is to be issued on the last payment.

LEHIGH VALLEY TRACTION.—The Lehigh Valley Traction reorganization committee expect within a few weeks to have the audit report of the American Audit Appraisement Company for the last half of the year 1903. They will then, it is stated, be prepared to offer a reorganization plan within a reasonably short time. This has been delayed because 1902 was an unusually bad year on account of flood damages, and it was desired to base the plan on a normal year such as 1903 has been. The physical examination of the properties by Mr. Foster was completed months ago. Signatures are being obtained from Philadelphia & Lehigh Valley Traction bondholders to a written agreement favoring the application for the proposed issue of about $160,000 receivers' certificates.

AUGUSTA RAILWAY & ELECTRIC.—Mr. James U. Jackson has completed arrangements by which the control of the Augusta-Aiken Company, the Augusta Railway & Electric Railway Company, Augusta & Aiken Railway Company, North Augusta Land Company and all the interests which Mr. Jackson organized in and around Augusta, are to be reorganized, controlled entirely by Augusta people, with himself as president. A year or so ago Mr. Jackson completed a transaction by which a majority interest in the Augusta Railway & Electric Company was secured by the Augusta-Aiken Railway, and now he has also purchased the minority interest, and both companies will be under one management. The transaction required the raising of about $1,000,000.

NORTHWEST ELEVATED OF CHICAGO.—The Northwest Elevated, of Chicago, reports as follows for the year ended December 31, 1903, as the result of electric traction:

	1903.	1902.	1901.
Gross	$1,542,039	$1,410,998	$1,100,863
Operating expenses	345,247	464,401	376,140
Net	$996,792	$946,597	$724,723
Charges	794,257	757,173	565,435
Surplus	$202,535	$189,424	$159,288

UNITED GAS & ELECTRIC.—The income account of the constituent companies of the United Gas & Electric Company for the year ended December 31, 1903, follows:

	1903.	1902.	Changes.
Gross	$1,224,047	$1,115,297	Inc. $108,750
*Expenses	1,010,363	914,887	Inc. 95,476
Net	$213,684	$200,410	Inc. $13,274

*Includes all costs of operation, insurance, taxes, depreciation and interest.

PITTSBURG BELL TELEPHONE.—The annual meeting of the Central District & Printing Telegraph Company will be held in Pittsburg February 11. The question of increasing the capital stock from $10,000,000 to such an amount as may be decided upon at the meeting will be submitted for the approval of the stockholders. Of the $10,000,000 stock outstanding, the American Telephone & Telegraph owns $6,191,290.

COMMERCIAL CABLE.—Reports show that Commercial Cable stock has recently been active and higher in Montreal on purchases growing out of the steadily increasing earnings and particularly because of the large business of the new Pacific cable and the promise of large earnings as war news becomes more important. The company has been extending its business by putting earnings into new construction which has added largely to equity values.

LONG ISLAND TROLLEY MORTGAGE.—The Central Long Island Electric Railroad, which purposes to operate from Port Jefferson to Patchogue, L. I., has been granted authority by the New York State Railroad Commission to issue a mortgage on its property for $500,000. The Ithaca-Cortland Traction Company has been authorized to issue a mortgage for $650,000. The companies are to use the proceeds of the mortgages for purposes of construction.

CINCINNATI STREET RAILWAY.—The next dividend on Cincinnati Street Railway stock in April will be at the rate of 6 per cent. per annum, guaranteed by the Cincinnati Traction Company. The dividend has been graduated from a 5 per cent. rate covering a period of several years.

STROWGER TELEPHONE.—The directors of the Strowger Automatic Telephone Company have issued a statement to stockholders saying the company is prosperous and that the dividend rate of 1 per cent. yearly will be increased shortly.

Commercial Intelligence.

THE WEEK IN TRADE.—Reports received by the mercantile agencies indicate that the weather conditions have been unfavorable throughout a wide area, and while in some instances helpful to retail trade, extreme cold or heavy snows have rather sharply checked spring trade and retarded transportation. There is also a quieter feeling in several lines of speculation and of industry, the exception to this being found in the south where, stimulated by the extraordinarily high cotton prices, preparations for the planting of an enormous acreage are going forward. A turn in the tide of speculation occurred and brought about lower prices for most of the cereals and securities. Staple prices, however, are generally very strong. Reports from the iron and steel trade are somewhat unsatisfactory. The railroads are still out of the market for rails, and finished products except at a few western markets are rather duller. A despatch received during the week from Montreal stated that the Pennsylvania Steel Company had obtained a contract from the Canadian Pacific Railway for 40,000 tons of 80-lb steel rails at $21.50 a ton, and that the United States Steel Corporation had also quoted for the contract at the same figure, but had failed to secure it. Structural material is quiet, but there is an active demand for wire, wire products and tubing at Pittsburg. Lumber and kindred industries are very active at all southern points. The pig iron production for 1903 surpassed expectations, the large decrease of the second half having been offset by the immense production of the first six months. The total output—18,009,000—exceeded by one per cent. the record production of 1902. Copper prices declined, but otherwise the situation is unchanged. The official quotations are: Lake, 12⅝ to 12⅞c.; electrolytic, 12½ to 12¾c.; and casting stock, 12⅜ to 12⅝c. Outside lots can be purchased at concessions from these figures of about ⅛ cent. The exports have been going on at an unexpected rate. It was noted last week that the total shipment for the month would probably reach 20,000,000 tons, and notwithstanding this heavy drain upon the available supplies, the metal was freely offered. This is taken to indicate that there are ample stocks in the hands of producers. The business failures for the week ending January 28, according to *Bradstreet's*, aggregated 242 against 266 the week previous, and 230 in the corresponding week last year.

EUREKA TELEPHONE EQUIPMENT.—The Belvidere Telephone Company, at Belvidere, Ill., in order to meet its service and render it more rapid have contracted with the Eureka Electric Company, of Chicago, and Genoa, Ill., to equip the 800-line express switchboard which it now has with the Eureka flashlight transfer system, consisting of 56 trunking lines having lamp signals at each end of the trunk. This trunking system will be able to accommodate 1,000 lines, as there will soon be that number in use. This board is also to be equipped with new listening and ringing keys and Eureka flashlight supervisory. The addition of the above apparatus gives the operator complete flashlight supervision over all calls, both trunking and those in her own section, and will greatly facilitate her work, enabling her to take care of more calls than would otherwise be possible. Among recent shipments are one Eureka magneto express switchboard of 400 capacity to McPherson Telephone Company, McPherson, Kan.; one 100-capacity board to Lawton Telephone Company, Lawton, Iowa; one 100-capacity board to Indiana Electric Company, Hillsdale, Ind.; one 100-capacity board to Citizens' Mutual Telephone Company, Newport, Ind.; one toll line board to J. E. Briglin, Orleans, N. Y.; one 100-capacity board to Larue Co. Telephone Exchange Company, Hodgenville, Ky.; one combination telephone and switchboard and one 100-capacity board to Quincy Mining Company, Hancock, Mich.; one 100-capacity board to Jas. A. Helm, De Soto, Ill.; one 100-capacity board to Chas. Causey, West Union, Ind.; one 100-capacity board to Mitchell Telephone Company, Georgia, Ind.; one 50-capacity board to Theresa Union Telephone Company, Theresa, Wis.; one 25-capacity board to Morgantown Telephone Company, Morgantown, Ind.; one combination telephone and switchboard to J. W. Reynolds, Simpson, Ill.; also a large shipment of telephones for Valparaiso, S. A., and a shipment of 100 telephones for San Salvador, C. A.

SOME C & C ORDERS.—The C & C Electric Company, 143 Liberty Street, New York City, reports recent receipt of British and African orders for motors. The British orders were secured through C. R. Heap, of London. A 45-hp series parallel equipment has been requisitioned for hoisting machinery in South African gold mines. The company has a number of domestic orders in hand for equipment to be installed in hotels, manufacturing plants, private residences, printing plants, etc. The Hotel Albert is to be equipped with two 60-kw and one 40-kw generator. These generators will be direct-connected to Payne engines of 90-hp and 60-hp capacity. This equipment will be used for lighting the hotel and driving the elevators. The Coco Cola Company, of Chicago, has ordered a 50-kw generator and marble switchboard. The generators will be direct-connected to a Shepherd vertical engine of 75-hp capacity. This outfit will be utilized for both light and power purposes. A 75-kw belted generator and switchboard has been ordered for light and power use in the quarries of William Bradley & Son, of Bedford, Ind. A 12½-kw generator has been called for, for direct connection to a Nash gas engine for lighting a private residence at Ossining, N. Y. A special slow-speed motor will be used for driving a large blower in the Union County Court House, Elizabeth, N. J. A 100-hp series parallel equipment has been ordered for driving a big Goss color press in the New York *Herald* plant.

COPPER IN ENGLAND.—The annual copper review of James Lewis & Son, of Liverpool, presents the following statistics of the total consumption of copper in the principal countries of Europe:

	1903.	1902.	1901.	1900.
Consumption of England	60,637	84,377	76,946	81,376
Manufactured copper exported ..	25,745	22,145	16,765	16,100
Sulphate of copper exported	13,361	10,822	9,004	10,728
Consumption of France	45,147	49,254	39,883	42,436
Consumption of Germany	*79,000	71,514	52,885	77,146
Consumption Am. copper in Italy, Austria and Russia	13,513	14,802	6,638	8,863
Total tons	243,403	252,914	202,121	236,649

* December estimated.

The circular says: "Our statistics of consumption for the year show an increase in the United States of 2,700 tons, and in Germany of about 7,500 tons, but a decrease in England of 17,740 tons and in France of 4,107 tons. The exports of manufactured copper (chiefly to India) and of sulphate have increased 6,139 tons. There is, however, little doubt that the actual consumption of England has not fallen off, but on the contrary has increased, the above apparent decrease being due to the greatly reduced stocks held by smelters and manufacturers. Much more copper has been used for electrical purposes; an increased quantity of sulphate has been consumed in Ireland, and though there is a decrease of 206,605 tons in the ships launched, there is an increase of 65,791 tons in the indicated horse-power of the marine engines supplied to them."

TORPEDO CABLE FOR JAPAN.—The Safety Insulated Wire and Cable Company, 114 Liberty Street, New York, reports brisk business. The New Haven plant of the company has been working at high pressure both night and day for some time past, and the Bayonne, N. J., works will begin continuous operation within the next few days. The Japanese Government has just requisitioned for a large lot of torpedo cable. A contract has been secured from the Philippine civil government for 30 miles of standard type cable which will be utilized to connect the last of the numerous islands with the mainland. The Safety Insulated Wire and Cable Company has taken contracts from the same source which will represent in all nearly 2000 miles of cable. The United States War Department has ordered a big quantity of range-finder cable for use in different fortifications along the Atlantic, Pacific and Gulf coasts. The company will ship next week 13 miles of single conductor cable to be used for connecting the fortifications of Puget Sound with Seattle, Washington.

THE WARREN ELECTRIC COMPANY, of Sandusky, Ohio, is shipping a 10,000-light generator to Martinsburg, W. Va.

GAS ENGINE POWER PLANTS.—The Power & Mining Machinery Company, of 52-54 William Street, New York City, reports some important recent work, especially for the Elmira (N. Y.) Water, Light & Railroad Company. Its contract with that company covers a four-cylinder American Crossley gas engine of the opposed type, with cylinders 32 in. in diameter x 36 in. stroke, to run 138 r.p.m. and to develop, under normal load, 1,300 brake hp, with natural gas containing 1,000 B.T.U. per cu. ft. This engine will be direct-coupled to a General Electric 60-cycle alternator of the fly-wheel type, and will run in parallel with their existing steam engines and with such other gas engines as they may install in the future. This engine will be used for both lighting and power; the direct current for their railway work secured by the use of rotary converters. The above order was placed after the Elmira Water, Light & Railroad Company had thoroughly investigated the gas engine field for over a year. In addition to the above, it has entered the following recent orders: Milford Electric Light Company, Milford, N. H., one 80-brake-hp high-speed Crossley gas engine, with cylinders 17 in. x 24 in., and one Crossley suction type producer plant of the same capacity. The Motor Engine Company, 15 William Street, New York City, one 20-brake-hp Crossley new type suction gas producer, to be installed at its Staten Island shops. The Ampara Mining Company, Philadelphia, Pa., one 190-brake-hp Crossley high-speed, double-cylinder gas engine, with cylinders 18½ in. x 24 in.; and two high-speed, single-cylinder Crossley gas engines, of 130-brake-hp each, with cylinders 20 in. x 30 in.; six 9-ft. x 15-ft. Loomis generators, with two 10,000 cu. ft. holders.

WESTINGHOUSE TURBINES IN A TEXTILE MILL.—The Westinghouse Machine Company has recently received an order from Joseph Benn & Sons for a turbo-generator set to be used in furnishing light and power for driving machinery in their new alpaca mills, which are to be built at Olneyville, R. I. This factory will be an American branch to their Yorkshire, England, mills. The turbine is of the Westinghouse-Parsons type, of 400-kw capacity, and is to operate under a steam pressure of about 150 pounds. Superheated steam will probably be used. The turbine will drive a 400-kw, three-phase Westinghouse alternator which will deliver power to the motors situated in the various parts of the mill for the purpose of driving machinery in the different departments. A 7½ x 7 Westinghouse standard engine type outfit is also being supplied and will be direct-connected to the generator rig for furnishing the exciter current. F. P. Sheldon & Co., mill engineer, of Providence, are now at work designing the plans for these mills.

LOS ANGELES ELECTRICAL SPECIALTY COMPANY, of 145 West Fourteenth Street, Los Angeles, Cal., has just completed a plant for the manufacture of high-grade dry cells for automobiles, gas engines, telephones, bells and all open-circuit work. The officers are David W. Coons, treasurer, and Arthur W. Coons, superintendent, who say: "With three years' practical experience with manufacturing batteries in the East, and several months spent in German and French battery works, investigating latest and most improved methods, and with the use of the best imported materials, we are able to produce the highest possible grade of cells and batteries for all electrical work where dry cells are used. We make all standard sizes and furnish estimates for special sizes where desired." They are catering primarily to Pacific Coast trade, but will be glad to hear from any part of the country.

THE AUTOMATIC ELECTRIC COMPANY, of Chicago, has recently sold complete telephone equipment for 1,000 stations to the Auburn Telephone Company, Auburn, N. Y. It has also received an order for 800 stations from the Ideal Construction Company, Hopkinsville, Ky. These figures are for present installation, and the ultimate capacity for each exchange will be 10,000 stations. About seven years ago the Auburn company installed an "Automatic" board with an ultimate capacity of 400 stations. This was soon filled, and in order to increase the list of its subscribers it purchased two manual boards of two operators' positions each and connected them with the automatic switchboard by means of trunk lines. The new equipment replaces the old "Automatic" board and the two manual boards which were later installed to give service in conjunction with it.

DENVER TROLLEY POWER HOUSE.—The maximum boiler horse-power in central power stations is only attained during a few hours of the day. During the greater part of the day the capacity required is much less than this maximum. On this account it has been found economical and practical to design the boilers and chimneys of ample capacity for this load and to force them above and up to the maximum by means of mechanical draft. This is applied with equal success to old and new plants. In the new power station of the Denver Tramway Power Company, Denver, Colo., mechanical draft is used as an auxiliary to the natural draft provided by a chimney 240 ft. high. Artificial draft is furnished by three Sturtevant electrically-driven steel plate fans. The boiler capacity of the plant is approximately 6,000 hp.

PAYNE ENGINEERING COMPANY, 26 Cortlandt Street, New York City, has issued recently the following notice, signed by Messrs. H. S. Whitney and M. A. Hudson: "We wish to inform our friends and customers, that we have completed arrangements whereby on January 1, 1904, we assumed the management of the Western business of the Ashcroft Manufacturing Company, the Hayden & Derby Manufacturing Company, the Hancock Inspirator Company and the Consolidated Safety Valve Company. On the same date the management of this company, with which we have been identified for the past eighteen months, was turned over to Mr. W. S. Montgomery."

FAILURES OF JANUARY.—The commercial failures in the United States in January, according to reports received by R. G. Dun & Co., numbered 1,406, with an aggregate defaulted indebtedness of $18,483,573, as compared with 1,269 failures in January, 1903, for $12,978,979. Of the 1,406, 271 were of manufacturers, for $6,687,637. On account of annual payments and inventory disclosures January is usually a month of many failures, but careful comparison shows that losses last month were heavier than in the corresponding month of any year since 1896, and heavier than in any month since May, 1900, excepting only December last.

EQUIPMENT FOR APARTMENT HOUSE.—The Construction Realty Company is about to ask estimates on the power plant to be installed in a new apartment house at Sixty-ninth Street and Broadway. There will be three direct-connected simple automatic high-speed engines, 13 x 12 in. The generators will be direct-current compound-wound multipolar machines, 125 volts, 65 kw. The wiring will be a two-wire 125-volt system. Percival Robert Moses is acting as consulting engineer for the company in this matter.

NATIONAL CARBON COMPANY.—The National Carbon Company, which closed its fiscal year January 31, has now completed the fifth year of its existence. The company has earned and paid dividends on the preferred stock at the rate of 7 per cent. If the company follows precedent it is expected to charge off about $300,000 for depreciation. Up to the last statement January 31, 1903, the company had charged off more than $900,000 since its inception, while the profit and loss surplus, according to the last statement, was only $156,000.

BALL ENGINE ORDER.—The Eastman Kodak Company, of Rochester, N. Y., has contracted with the Ball Engine Company, of Erie, Pa., for two 400-hp. vertical cross-compound engines, to be direct-connected to a 250-kw Crocker-Wheeler generator. The Ball Company has just installed two 350-hp vertical cross-compound, direct-connected units in the First National Bank Building, Chicago, and is also building two additional units of the same size for this plant.

CAHALL BOILERS FOR WORLD'S FAIR PLANT.—The important contract for boilers which will furnish the steam for nearly two-thirds the entire power plant for the World's Fair has just been awarded. The Aultman & Taylor Machinery Company, of Mansfield, O., secured the work. The boilers, 16 in number, will have an aggregate capacity of 7500 boiler hp. They will be installed in the Steam and Fuel Building at St. Louis.

THE GREAT NORTHERN POWER COMPANY, of Duluth, Minn., is asking for proposals for vertical turbines to operate under a head of 365 ft. at 250 r.p.m., together with other necessary apparatus. According to the present plans of the company it is expected to have a 35,000-hp plant in operation in 1905. The plans provide for an increase of power up to 80,000 hp. Another hydraulic installation of 12,000 hp at a 70-ft. dam is also in contemplation.

PELTON WATER WHEELS FOR SOUTH BRAZIL.—The Pelton Water Wheel Company, 143 Liberty Street, New York, has secured a contract for a 300-hp water wheel outfit which will be used for developing power for lighting a small city in South Brazil. The generator—200 kw—will be built by the General Electric Company. The contracts came through Guinle & Aschoff, of Rio Janeiro.

MEXICAN HYDRAULIC PLANT.—The construction of a hydraulic plant is projected on the River Plomosas in the district of Rosario, State of Sinoloa, Mexico. An American, Dell Linderman, who operates extensive mines in that district, is primarily interested in the project. He intends to operate his mines by electric power. The plant will have a capacity of about 1500 hp.

SALE OF LIGHTING PLANTS.—The J. S. Maurer & Co. agency, 804 Monadnock Block, Chicago, reports the sale of central electric light plants, for investment purposes, in the towns of Pecatonica and Pittsfield, Ill., and Blairstown, Iowa.

McCREARY SPECIALTIES FOR EUROPE.—The A. A. McCreary Company, of 136 Liberty Street, New York, has some substantial orders in hand for its electrical specialties for shipment to Mexico City, London and Paris.

DIRECTORY OF ELECTRICAL ASSOCIATIONS, SOCIETIES, ETC.

(Published first issue of each month.)

American Electrochemical Society. Secretary, C. J. Reed, 929 Chestnut Street, Philadelphia, Pa. General meeting, Washington, D. C., April 7, 8 and 9, 1904.

American Electro-Therapeutic Association. Secretary, Dr. C. E. Skinner, New Haven, Conn.

American Institute of Electrical Engineers. Secretary, Ralph W. Pope, 95 Liberty Street, New York. Meetings, last Friday each month.

American Railway, Mechanical & Electrical Association. Secretary, Walter Mower, 12 Woodward Ave., Detroit, Mich.

American Society of Municipal Improvements. Secretary, G. W. Tillson, Brooklyn, N. Y. Next meeting, St. Louis, 1904.

American Street Railway Association. Secretary, T. C. Pennington, 2020 State Street, Chicago.

Association of Edison Illuminating Companies. Secretary, W. S. Barstow, New York City and Portland, Ore.

Canadian Electrical Association. Secretary, C. H. Mortimer, Toronto, Ont. Next meeting, Hamilton, Ont., 1904.

Chicago Electrical Association. Secretary, W. B. Hale, 242 South Jefferson Street, Chicago.

Colorado Electric Light, Power & Railway Association. Secretary, George B. Tripp, Colorado Springs, Col. Annual meeting last Wednesday in October.

Connecticut State Street Railway Association. Secretary, E. W. Poole, Bridgeport, Conn. Annual meeting in November.

Engine Builders' Association of the United States. Secretary, F. P. Ide, Springfield, Ill. Next meeting, December, 1903.

Electrical Trades Society (Member National Electrical Trades Association). Secretary, A. P. Eckert, 39 Cortlandt Street, New York. Board of Directors meets second Friday of each month.

Illinois State Electric Association. Secretary, H. E. Chubbuck, LaSalle Ill.

Indiana Public Utilities Association. Secretary, A. M. Barron, Indianapolis, Ind.

Independent Telephone Association of the United States. Secretary, Frank G. Jones.

Independent Telephone Association of Southern Indiana. Secretary, E. W. Pichardt, Huntingburg, Ind.

International Association of Municipal Electricians. Secretary, Frank P. Foster, Corning, N. Y.

Interstate Independent Telephone Association. Secretary, E. M. Coleman, Louisville, Ky.

Iowa Electrical Association. Secretary, W. S. Porter, Eldora, Ia.

Iowa Telephone Association. Secretary, C. C. Deering, Des Moines, Ia. Annual meeting, Des Moines, March 8, 1904.

Kentucky Independent Telephone Association. Secretary, James Maret, Mount Vernon, Ind.

Maine Street Railway Association. Secretary, E. A. Newman, 471 Congress Street, Portland, Me.

Massachusetts Street Railway Association. Secretary, Charles S. Clark, 70 Kilby Street, Boston, Mass. Meets second Wednesday of each month, except July and August.

National Arm, Pin & Bracket Association. Secretary J. B. Magers, Madison, Ind. Next meeting St. Louis, July, 1904.

National Electrical Contractors' Association of the United States. Secretary, W. H. Morton, 44 Whitesboro Street, Utica, N. Y. Next meeting St. Louis, Mo., September 14, 15 and 16, 1904.

New England Street Railway Club. Secretary, J. H. Neal, 101 Milk Street, Boston, Mass. Meets last Thursday of each month.

New York Electrical Society. Secretary, G. H. Guy, 114 Liberty Street, New York.

National Electric Light Association. Secretary, Ernest H. Davis, Williamsport, Pa. Next meeting, Boston, Mass., May 24, 25 and 26.

Northwestern Electrical Association. Secretary, T. R. Mercein, 85 Michigan Street, Milwaukee, Wis.

Ohio Street Railway Association. Secretary, Chas. Currie, Akron, Ohio.

Ohio Electric Light Association. Secretary, D. L. Gaskill, Greenville, Ohio.

Ohio Society of Mechanical, Electrical and Steam Engineers. Secretary, C. J. Miller, Canton, O.

Southwestern Electrical Association. Secretary, J. L. Ellis, Oklahoma City, Okla. Next meeting, Dallas, April or May, 1904.

Southwestern Gas, Electric & Street Railway Association. Secretary, Frank E. Scovill, Austin, Texas.

Street Railway Accountants' Association of America. Secretary, W. B. Brockway, 40 Morris Street, Yonkers, N. Y.

Street Railway Association of the State of New York. Secretary, W. W. Cole, Elmira, N. Y. Next meeting, Utica, N. Y., Oct. 11 and 12, 1904.

United Electrical Contractors' Association of New York State. Secretary, F. Fish, Rochester, N. Y.

Vermont Electrical Association. Secretary, C. C. Wells, Middlebury, Vt.

General News.

THE TELEPHONE.

MOBILE, ALA.—At the meeting of the Home Telephone Company the following-named officers were elected for the ensuing year: E. Eichold, president; A. S. Lyons, treasurer; Robert L. Douglas, secretary.

OXNARD, CAL.—When the franchise for the Home Telephone Company was refused by the town trustees some time ago, the Sunset Telephone Company made certain promises which are being amply fulfilled. Continuous service has been installed, in place of special hours on Sundays, evenings and holidays. A force of fifteen men has entirely rebuilt the town system, replacing the old iron wire with copper wire, changing the ten-party lines to two and four-party lines, installing two new switchboards, putting in new poles, painting them and placing them wherever possible in the alleys. The toll lines between Oxnard and Montalvo have been rebuilt and men are now at work stringing a line so that Oxnard will be able to call Los Angeles directly.

CARROLLTON, GA.—The Gainsboro Telephone Company, of Carrollton, has purchased the lines of the Commercial Telephone Company at Atlanta and has merged the latter into its own property. This acquisition gives the Gainsboro Company about 400 miles of line, 10 city exchanges and 60 stations, all under the control of the Carrollton exchange.

OBLONG, ILL.—The Oblong Telephone Company has been incorporated with a capital stock of $6000. The names of the incorporators are E. T. Shire, F. P. Willard and Zach Wirt.

LOGANSPORT, IND.—The Home Telephone Company has increased its rate for business telephones from $18 to $30 per year.

FAIRMOUNT, IND.—The Citizens' Telephone Company is installing a new switchboard which will accommodate an additional 100 subscribers.

INDIANAPOLIS, IND.—The Denver County Telephone Company has been incorporated with a capital stock of $3000. The directors are I. L. Eckenberry and others.

ZIONSVILLE, IND.—The Citizens' Telephone Company, of Zionsville, has been incorporated with a capital stock of $15,000. The officers of the company are: President, James O. Hurst; secretary and treasurer, H. F. Gallimore.

INDIANAPOLIS, IND.—Contracts have been made by the Board of Public Safety for telephone service for the Police Department. The new company will furnish 74 telephones and a new switchboard at the headquarters for $1250 and the old (Bell) company will furnish 84 instruments for $1248.

MUNCIE, IND.—The strike of the Electrical Workers' Union of Delaware and Madison Counties Telephone Company, which began last April was formally declared off Jan. 12, a compromise having been effected. It is given out that hereafter none but union electrical workers will be employed by the company.

INDIANAPOLIS, IND.—The Independent telephone people of Indiana are somewhat concerned over the action of Postmaster-General Payne, in ordering the independent telephones removed from the post offics in the Northwest. Should such an order be applied to Indiana it would displace or silence a large number of telephones.

HOLLANDSBURG, IND.—The New Home Telephone Company has been organized by the citizens of this place. An exchange will be established and lines constructed in Wayne and Randolph counties. Connections will be had with towns in Ohio that are connected with the independent companies. Oliver Spencer is secretary of the new company.

SHELBYVILLE, IND.—A new section of switchboard is being put in at the exchange of the Mutual Telephone Company of this city which will increase the capacity to 1100 lines. Another line will be built between this city and Indianapolis as the two lines which are now stretched between the two cities are not sufficient to carry the heavy business of the company.

INDIANAPOLIS, IND.—Judge Anderson, of the United States District Court, has refused the petition of the Cumberland Telephone Company, of Evansville, for a rehearing of its suit against the city to prevent the city authorities from ousting it from the streets for the lack of a franchise to operate therein. The case will now be appealed to the U. S. Court of Appeals.

BROWNSBURG, IND.—At the annual meeting of the Brownsburg Telephone Company J. S. Thorp was elected president; D. R. Marsh, secretary; Alpha Medsker, treasurer, and J. R. Flinn, superintendent of construction. The company is figuring with both the Bell and the Independent Telephone Company relative to getting a direct line to Indianapolis and there is apparently some rivalry between the two companies.

DELPHI, IND.—The Carroll Telephone Company, of this city, and all the co-operative companies throughout the county have effected a consolidation and all the lines are now connected for business. The arrangement is on trial for three months, and if it proves satisfactory a permanent contract will be made. It gives service all over the country, and connects nearly 2000 rural telephones with the local exchange in this city.

ANDERSON, IND.—The December earnings of the Delaware and Madison Counties Telephone Company amounted to $6550 gross; expenses were $2802; interest, $1441; surplus to be applied to stock, $2306. The surplus for December was $2211. The company which operates the Muncie, Anderson, Elwood and Alexandria exchanges is expected soon to reach a dividend basis, although only in operation a year or so. At Alexandria the company is hustling to keep ahead of the Central Union and to that end a new section of board, cable and other equipments to handle 200 or 300 more telephones will be installed.

DES MOINES, IA.—The Mutual Telephone Company contemplates issuing bonds for the extension and improvement of its system.

SLOAN, IA.—The Lawton Telephone Company has been incorporated with a capital stock of $2000. The directors are J. H. Abernathy, R. I. Marshall and others.

OSCEOLA, IA.—The Murray & Lacelle Telephone Company, of Osceola, has been incorporated with a capital stock of $450. The incorporators are George Coon, Jacob Reueder and E. D. Hamm.

STRATFORD, IA.—The Stratford Independent Telephone Company has purchased the system and franchise of the Chamberlain Independent Telephone Company. The name of the new company will probably be changed to Hamilton County Independent Telephone Company. Mr. C. Williams is president.

HOPKINSVILLE, KY.—The Hopkinsville Home Telephone Company has been incorporated with a capital stock of $100,000. R. E. Cooper is president.

BRAINERD, MINN.—It is stated that the Northwestern Telephone Exchange Company will build a line to Walker, Minn., in the spring.

SPRINGFIELD, MINN.—The Citizens' Mutual Telephone Company has been formed here with a capital stock of $25,000. It will build a local and rural system.

HELENA, MONT.—The city council has decided to submit to a vote the proposition of granting a franchise to the Rocky Mountain Bell Telephone Company.

KANSAS CITY, MO.—The Independent Telephone Construction Company, of Kansas City, has been incorporated for the purpose of constructing toll lines of the Home Telephone Company. It is capitalized at $100,000, all paid up. J. S. Brailey, Jr., of Toledo, Ohio, is one of the principal promotors of the enterprise.

HANNIBAL, MO.—An appeal in the case of the Missouri & Kansas Telephone Company, which was fined $150 in the police court on the charge of violating the city ordinances by constructing lines within the city limits without securing the consent of the city council, has been taken to the Hannibal court of common pleas. The case is one in which the city seeks to compel the company to take out a franchise.

LINCOLN, NEB.—The Independent telephone companies of the state have asked the Omaha commercial club to use its influence in getting through the city council of Omaha a franchise for the establishment of an independent telephone exchange in that city, with which all independent companies may connect. The request indicates that a fight will be made on the Bell Telephone people by the independents in Nebraska.

JERSEY CITY, N. J.—The corporation council has drafted a bill providing for the placing underground of telegraph, telephone and other wires. The bill will be introduced in the legislature.

LE ROY, N. Y.—The Canton & Le Roy Telephone Company has been granted a franchise to conduct business in Canton.

LOCKPORT, N. Y.—The Niagara Telephone Company, of Barkers, N. Y., has been absorbed by the Bell Telephone Company, of Buffalo. The independent company had 127 subscribers.

NEW YORK, N. Y.—Sealed bids were received by the police commissioner of the Police Department of the City of New York on Feb. 1 for furnishing and delivering telegraph and telephone supplies.

PRATTSBURGH, N. Y.—The Prattsburgh Overland Telephone Company has filed articles of incorporation at Albany with a capital stock of $10,000. The directors are Estelle Conine, G. T. Conine and L. H. Conine.

UTICA, N. Y.—At the annual meeting of the Utica Home Telephone Company the following-named officers were elected: President, Edgar B. Odell; vice-president, H. F. Miller; treasurer, Edward Bushinger; secretary and manager, C. H. Poole.

BYRON, N. Y.—The Byron Telephone Company has been organized and incorporated to operate a system in Genesee and Orleans counties with an exchange at Byron. The capital stock is $1200. The board of directors is composed of Dr. Prince, A. G. Steele, I. W. White, C. H. Green, H. C. Norton, F. C. Walker and H. C. Warker

ELMIRA, N. Y.—The stockholders of the York State Telephone Company held their first annual meeting a few days ago. Officers were elected as follows: President, W. D. Barnard; vice-president, Edward Davis; secretary and treasurer, Robert M. Dougal. The annual report shows that the increase in the number of telephones during the year was from 2461 to 3617, which is a growth of 50 per cent.

LIBERTY CENTER, OHIO.—The Farmers' Mutual Telephone Company has been organized here. Mr. A. C. Clifton is president. The company has 46 subscribers.

AKRON, OHIO.—The Akron People's Telephone Company directors have elected Will Christy, president; J. S. Benner, secretary; W. F. Laubach, treasurere and general manager.

URBANA, OHIO.—Stockholders of the Urbana Telephone Company re-elected the present officers. The company is planning to make improvements to its exchange.

CHERRYVALE, OHIO.—The Cherryvale Mutual Telephone Company has been incorporated with a capital stock of $350. The directors are J. H. Scofield, O. N. Hamilton and others.

DELPHOS, OHIO.—The Delphos Home Telephone Company has secured a 15-year franchise, being an extension of the old franchise. Having settled this point, the company will now make improvements.

LIMA, OHIO.—The Ideal Construction Company, of this city, will erect a telephone exchange at Hopkinsville for the Hopkinsville Home Telephone Company. R. E. Cooper, of Lima, is president of the company.

CRESTLINE, OHIO.—The Central Union Telephone Company has a franchise ordinance pending in Crestline and hopes to secure the grant, as this is the only town in the district not reached by the Bell Company.

GIRARD, OHIO.—An independent company is being organized here and will ask for a franchise. At present the Bell Company has the field alone and a great many people are dissatisfied because of a recent advance in rates.

PLAIN CITY, OHIO.—The Home Telephone Company, of this place, has been incorporated with a capital stock of $50,000. The company will operate in Franklin, Union and Madison counties. The names of the incorporators are Calvin Liggett, C. W. White, L. H. Elliott, F. N. Mattoon, L. S. Lane and L. Worthington.

NEW LEBANON, OHIO.—V. E. Weaver, of this place, is organizing a mutual telephone company among the farmers of this district. Each member of the company will furnish his own poles and wire. An exchange will be located in South Lebanon. Brooksville, Liberty, Johnsville, Arcanium, Alexandria and Germantown will be connected.

BRYAN, OHIO.—The Bryan Telephone Company has secured control of and absorbed the Williams County Toll Line Company. Nearly $100,000 worth of property changes hands by the deal. O. L. Spangler, formerly auditor for the Williams County Company, has been made general manager of the new company. The other officers remain as heretofore.

INGERSOLL, O. T.—The Union Telephone Company, of Ingersoll, has been incorporated with a capital stock of $10,000 by A. W. Leonard, and M. M. Taylor, of Driftwood; B. F. Blue, E. Bradley and J. B. McGinniss, of Ingersoll.

NEWKIRK, O. T.—A charter has been issued by the secretary of state to the Newkirk Home Telephone Company which has been organized with a capital stock of $5000. The incorporators are J. H. Smock, J. H. Thompson and Guy Stovall.

AMES, O. T.—The Phœnix Telephone Company, of Ames has been incorporated with a capital stock of $10,000 by A. Mathis, B. F. Hogard and W. H. Mathis.

TAMAQUA, PA.—The telephone exchange of the United Telephone Company has been destroyed by fire.

SCRANTON, PA.—The Pennsylvania Telephone Company has expended $200,000 in the general improvement of its service in this city, including the placing of the wires underground. The work is not yet completed. Provision has been made for the installation of a new central energy switchboard with a capacity of 10,000 lines.

READING, PA.—At the annual meeting of the directors of the Consolidated Telephone Company of this city, it was reported that there are now 1800 telephone connections in this city, while contracts for over 400 more have been made. The following-named gentlemen were elected officers: President, Robert E. Wright; vice-president, C. W. Kline; secretary and general manager, S. E. Wayland; treasurer, C. M. W. Keck.

TRIPP, S. D.—The Tripp Telephone Company has been incorporated with a capital stock of $2000.

COLORADO CITY, TEX.—The Texas & Pacific Telephone Company has increased its capital stock from $30,000 to $40,000 and has changed its headquarters from Abilene to this place.

BATSON, TEX.—A telephone system will be established here by the Southwestern Telegraph & Telephone Company. J. E. Farnsworth, of Dallas, Tex., general manager, can give information.

SALT LAKE CITY, UTAH.—The experiments of the Oregon Short Line Railway Company in establishing a telephone system in connection with its telegraph lines has proved an entire success, and many extensions in this direction will be made in the near future.

McDONALDS MILLS, VA.—The North Fork Telephone Company with a capital of $5000 has been incorporated.

ETNA MILLS, VA.—The Richmond & Ayletts Telephone Company has decided to extend its line from Etna Mills to Hanover.

VIRGILINA, VA.—The Virgilina Telephone Company has declared a dividend of 6% and re-elected the present officers. This company operates over 42 miles of wire, connecting at South Boston, Va., with the system there, also with systems in other places.

PORTAGE, WIS.—The Portage Telephone Company has increased its capital from $3000 to $30,000.

MONCLOVA, STATE OF COAHUILA, MEX.—The Monclova Telephone Company will extend its system and make other important improvements.

HERMOSILLO, MEX.—The Mexican Government is extending its system of telegraph wires to all parts of this state. A large amount of material is required for this work of improvement.

ELECTRIC LIGHT AND POWER.

BIRMINGHAM, ALA.—It is proposed to construct an electric light plant in the West End at a cost of between $10,000 and $15,000. P. S. Milner, of the West End, is interested.

STOCKTON, CAL.—R. G. Paddock has applied for an electric light franchise, and bids for same will be received Feb. 19. Eugene D. Graham is county clerk.

WILLIMANTIC, CONN.—At the annual meeting of the Willimantic (Conn.) Gas & Electric Light Company the officers elected were: Directors, J. F. Church, Geo. A. Lewis, Emerson Stone, David F. Tilley and Chas. F. Evans who succeeds his father—the late Edwin Evans; president, J. F. Church; treasurer, George A. Lewis; assistant treasurer, D. F. Tilley; secretary, C. W. Noyes.

ANDERSON, IND.—The Philadelphia Quartz Company, of this city, has abandoned gas, coal and steam for power in its local plant in favor of electricity. It is the first factory in this city to do so.

VINCENNES, IND.—The City Council recently voted down the ordinance relating to the New City Electric Lighting Company, in which Mr. P. K. Tyng is interested. The statement that the ordinance was passed was erroneous.

LOGANSPORT, IND.—The recent flood damaged the local electric light plant to the amount of many thousand dollars. The north wall gave way and tumbled into the river. The plant was compelled to close which left the city in darkness.

TIPTON, IND.—The municipal electric light plant, erected several years ago at a cost of $40,000, is overloaded and the service is not satisfactory. It is planned to enlarge the plant and the old dynamos will be replaced with machines with twice the capacity in order to keep pace with the growing city.

IDAHO FALLS, IDA.—Geo. Chapin, president of the Idaho Power & Transportation Company, writes that it is proposed to construct a plant on Snake River, at a cost of $75,000. No engineer has been selected as yet.

DE WITT, IA.—At the last annual meeting of the stockholders of the De Witt Electric Light & Power Co., it was decided to expend a few thousand dollars in improving, and enlarging the capacity of the plant as the business has outgrown the present facilities. It will be necessary to install some new and larger machinery.

SIOUX CITY, IA.—It is reported that about $24,000 will be expended on improving the city lighting plant.

LIVERMORE FALLS, ME.—The Livermore Falls Water Company and the Livermore Falls Light & Power Company, which are practically one concern, and the Richmond Manufacturing Company, have elected Edwin Riley, president; John H. Maxwell, treasurer and clerk, and Fred E. Riley, engineer.

GREAT BARRINGTON, MASS.—The Great Barrington Electric Company has elected officers as follows: President, Frank Curtiss; vice-president, treasurer and general manager, Parley A. Russell; superintendent, Clyde Parrish.

RAPID RIVER, MICH.—The business men are considering the installation of an electric light plant.

NEGAUNEE, MICH.—The Central Construction Company, of Oshkosh, Wis., has secured the contract for improvements to the electric light plant, for about $15,000.

FLINT, MICH.—Wm. L. Fisher, Superintendent of Water Works, and A. W. Hall, City Engineer, have been requested to report on the cost of installing a municipal electric light plant of about 150 enclosed arc lamps, requiring about 40 miles of wire.

SWANVILLE, MINN.—It is reported that an electric plant will be installed at the milling plant of Koenig Bros. & Meschke.

HANNIBAL, MO.—The citizens voted Jan. 11 to issue $100,000 bonds for rebuilding the electric light and power plant.

BALTIMORE, MD.—At a meeting of the board of directors of the United Electric Light & Power Company, Messrs. A. N. Brady, Samuel A. Beardsley, Nicholas F. Brady and Thomas E. Murray, of New York, were elected directors to represent the new interests who recently purchased a large bulk of the stock of the lighting company.

CONCORD, N. C.—Jas. C. Fink, City Clerk, writes that the matter of constructing an electric light plant is being considered. Dr. W. D. Pemberton is Chairman of the Committee.

WINSTON-SALEM, N. C.—The Board of Aldermen on Jan. 20 awarded to the Fries Mfg. & Power Company the contract for lighting the city for a period of 13 years, beginning March 31, at $60 per light per year.

LEBANON, N. H.—The Lebanon Electric Light & Power Company has elected officers as follows: President, W. S. Carter; vice-president, George S. Rogers; clerk, G. C. Whipple; treasurer, H. M. Day.

CLEMENTON, N. J.—The Clementon Township Electric Light Company has surveyed a route for an extension of its system to Clementon and Overbrook.

JERSEY CITY, N. J.—The Jekyl Island Light & Power Company, of Jersey City, has been incorporated; capital, $50,000. Incorporators: Chas. Lanier, Robt. W. De Forest, and John L. Scrymser.

TRENTON, N. J.—The Columbus Public Service Company, with an authorized capital of $1,500,000, was incorporated at Trenton, N. J., to make and distribute heat, light and power. The incorporators are Horace S. Gould, H. O. Coughlan, of New York, Joseph M. Mitchell, of Newark, B. S. Lantz, of Brooklyn, and Louis B. Dailey, of Jersey City. The location of Columbus is not stated in the dispatches.

IRVINGTON, N. J.—The Council on Jan. 5 opened bids as follows for lighting the town: United Electric Company, for 430 lights of 30-cp each, for a period of five years, $15 per lamp; on a three-year contract, $15.50, and for one year, $16. Wm. L. Glorieux, of Irvington, offered to purchase necessary generators and furnish the current from his smelting works at Enterprise Hill at $9 per lamp per year.

OWEGO, N. Y.—The stockholders of the Owego Light & Power Company have elected W. S. Truman, president; Hon. W. G. Phelps, vice-president, and G. F. Andrews, secretary and treasurer.

POUGHKEEPSIE, N. Y.—Officers of the Poughkeepsie Light, Heat & Power Company have been elected as follows: F. R. Bain, president; T. R. Beal, secretary; William Shickle, treasurer.

NEWBURGH, N. Y.—At the annual meeting of the Newburgh Electric Light, Heat & Power Company, officers were elected as follows: Wm. R. Beal, president and general manager; T. R. Beal, secretary and treasurer.

OGDENSBURG, N. Y.—The town of Waddington, at a special election a few days ago, voted to sell its municipal electric light plant and water power and rights to a Canadian company for $3750, the amount which now remains unpaid on the plant. It is stated that the municipal operation of the plant did not prove satisfactory.

ATHENS, OHIO.—The new municipal lighting plant is being erected and a number of manufacturing establishments are contracting for power.

SIDNEY, OHIO.—The Sidney Electric Light Company will install two new engines; an incandescent machine and will make other improvements to its system.

COLUMBUS, OHIO.—The recent floods and high water caused serious damage to electric lighting plants in a number of Ohio cities. Lighting plants at Columbus, Toledo, Youngstown, Grand Rapids and other towns were out of service, leaving portions of the towns in darkness.

MECHANICSBURG, OHIO.—T. J. Long has closed a contract with the village council to install a lighting plant and furnish light for the town as well as for private service. He agreed to supply 30 arc lights at $66 each, and $60 for each additional lamp. The plant is to be completed by May 1, 1904. Work will start as soon as the weather permits.

NEW FREEDOM, PA.—Bids will soon be asked for water works and an electric light plant.

HARRISBURG, PA.—Bids will be received Feb. 19 for installing electric light and power in the county jail.

MARIETTA, PA.—The directors of the Elizabethtown & Marietta Light Company have decided to enlarge the plant.

BEAVER, PA.—Wm. H. Iron and Eugene S. Hoopes are on the committee to solicit subscriptions of an electric light plant, which is to be purchased by the borough.

HARRISBURG, PA.—The Southampton Light, Heat & Power Company, of Southampton township, Franklin County, has been incorporated with a capital stock of $5000.

HARRISBURG, PA.—The Middlespring Light, Heat & Power Company, of Southampton township, Cumberland County, has been incorporated with a capital stock of $5000.

READING, PA.—The mayor has vetoed the ordinance enabling the city to borrow $200,000 to establish a municipal electric light plant. The veto was sustained by the select council.

PROVIDENCE, R. I.—The Narragansett Lighting Company held its annual meeting last week in the office of the president when the following gentlemen were elected for the coming year: President and general manager, Marsden J. Perry; vice-president, Arthur H. Watson; assistant general manager, Arthur B. Lisle; treasurer and secretary, Edward A. Barrows. Mr. T. A. Pierce, who formerly held the office of treasurer and secretary, stated that the increasing business in the company required more time than he could give to it and he desired to be relieved of further responsibility after a continuous service of 18 years.

NASHVILLE, TENN.—Mr. J. W. Pentecost, superintendent of the city electric light plant, has submitted to the Board of Public Works his annual report for the year 1903. Two additional boilers have been installed during the year, increasing the boiler equipment of the plant by 200 horse-power and more than 70 miles of live wires have been put out. From 510 on Jan. 1 the arc lights were increased to 642 at the end of the year. There were 392 incandescent lamps put in during the year. The expense of operating amounted to $27,293.37. Twelve thousand dollars was paid in interest and into the sinking fund on account of light bonds. This $12,000 added to the cost of operation, makes $39,293.37. The wages and salaries of the employes amounted to $15,142.27. The amount expended for coal was $7,015.99. At the end of the year there were 1,839 incandescent lamps in service. The output for the year amounted to 1,433,014 kw-hours. Construction work during the year cost $39,822.17. Of this amount $14,000 was expended for boilers; $7,653 for engines and generators; $5,712.30 for wiring; $5,099.75 for labor; $1,797.43 for stationary equipment; $1,824 for poles, etc.; $1,579.93 for foundations. If all the construction were considered as repairs and renewals, the cost per kw-hour would figure out at about 6 cents per kw-hour, a very high rate of production and supply chiefly for arc lighting with overhead wires. Rate of depreciation is not stated, nor is distinction made between new investment and ordinary upkeep.

HILLSBORO, TEX.—E. D. Kelley, superintendent of the Hillsboro Gas & Electric Company, writes that it is proposed to purchase a 200-hp boiler.

CLEBURNE, TEX.—The Cleburne Gas & Electric Light Company, has been organized with a capital of $150,000, by J. F. Strickland, of Waxahachie; R. Vickery, of Ft. Worth, and others.

CLEBURNE, TEX.—The Cleburne Gas & Electric Light Company has been organized here with a capital stock of $150,000 by R. B. Sticher, J. F. Strickland, Osce Goodwin and M. B. Templeton, all of Waxahachie, and R. Vickery, of Fort Worth.

BALLINGER, TEX.—The Ballinger Light & Ice Company has been organized here for the purpose of constructing and operating an electric light and power plant. It has a capital stock of $10,000. The incorporators are W. A. Norman, R. B. Creasey, E. J. Hardgrave and Lewis Alexander.

DEL RIO, TEX.—J. W. Maxey, an engineer of Houston, is preparing plans for a large electric power plant which is to be established at San Felipe Springs, adjacent to this place. It is proposed to generate 375 horse-power by means of the flow of water from the springs. The electrical energy will be conducted to the town where it will be used for lighting and power purposes. It will also be transmitted to irrigation and manufacturing plants in this section. G. Bedell Moore, of San Antonio, who owns the San Felipe Springs, is back of the project.

PRAIRIE DU CHIEN, WIS.—The electric light plant at McGregor was totally destroyed by fire a few days ago, the loss being about $11,000.

BLACK RIVER FALLS, WIS.—The citizens have voted to issue $25,000 bonds to purchase the Owens water power to run the electric light plant.

LAMARTINE, WIS.—The Lamartine Peat, Light & Power Company has been organized with a capital of $150,000 by Dr. C. A. Beebe, C. T. Medberry, F. J. Rueping and others, to develop peat marshes in Lamartine. Application has been made for a franchise to furnish light and power.

The Electric Railway.

VENICE, ILL.—The management of the Granite City & Venice Electric Railway Company is preparing plans for a new power house and car houses at Venice.

CRAWFORDSVILLE, IND.—The Consolidated Traction Company is arranging to build a large power house in Crawfordsville in the spring. Edward Hawkins is president.

WABASH, IND.—The stockholders of the Wabash & Rochester Railway Company, organized to build a line from this city to Rochester, 35 miles, have elected the following officers: Charles Crane, president, P. E. Wilcox, vice-president; E. S. Pratt, secretary, and C. E. Barnum, treasurer.

BEDFORD, IND.—The City Council has granted an electric street railway franchise to a company of local men, including Col. A. C. Voris, W. M. Mathews, J. W. Gouser, M. N. Messick, E. B. Thornton, V. V. Williams, I. N. Glover and Frank Owens. The company will incorporate at once.

VINCENNES, IND.—The Western Indiana Traction Company has elected officers, as follows: Samuel Williams, of Vincennes, president; F. S. Robinson, of Cloverland, vice-president; John Le Croix, of Vincennes, secretary-treasurer. The company will build a line from this city to Terre Haute this spring.

WOLFSVILLE, MD.—The Catoctin Railway Comapny has been formed here to operate an electric railway. The officers are John H. Maugans, president; W. B. Stottlemyer, vice-president, and H. M. Warrenfeltz, secretary.

ESCANABA, MICH.—The Escanaba Electric Street Railway Company is to extend its line and make improvements to the power house.

BENTON HARBOR, MICH.—The Kalamazoo & Lake Michigan Electric Railway Company will soon begin the construction of its proposed line between Kalamazoo, Benton Harbor and South Haven, Mich. In all, 66 miles of track will be built. Estimates for building and equipping the line are now being received. The engineers are the Western Engineering & Construction Company.

MINNEAPOLIS, MINN.—The Minneapolis method of curing the spitting evil is to have the conductor hand the offender a red card, with the city ordinance about spitting printed on it.

CROOKSTON, MINN.—An electric railway throughout the Red River valley is planned by J. P. Booker and other capitalists of Crookston. Eastern capitalists have agreed to put $100,000 into the enterprise if local capital can raise an additional $100,000.

OMAHA, NEB.—The Omaha & Council Bluffs Street Railway Company announces that the new 6000-hp generator station will be completed at a cost of $500,000. The line between South Omaha and Omaha will be extended to Fort Crook, 5 miles from the present terminus. The Sherman Avenue line, the West Leavenworth Street and Walnut Hill lines will be rebuilt.

UTICA, N. Y.—It is stated that an extensive system of electric railways will be constructed in the North Woods next summer. The first step in the projected enterprise will be the building of a line connecting upper St. Regis Lake and Lake Clear with Paul Smith's. Power for the proposed road will be taken from Franklin Falls in the Saranac River, 20 miles away.

WILLIAMSBURG, N. Y.—A railroad company known as the Eastern Traction Company of Waterbury, Conn., has had representatives in Williamsburg for several weeks, getting the consents of property owners on Roebling Street, from the plaza of the new Williamsburg Bridge, for an electric road through Greenpoint into Long Island City, connecting at Astoria with the new Blackwell's Island Bridge. The promoters of the movement, in addition to obtaining consents, are giving an opportunity to property holders of becoming stockholders in the railroad company. It is stated that many consents had already been obtained, and that the company is capitalized at $5,000,000.

BROOKLYN, N. Y.—The American Realty Traffic Association of Brooklyn has been incorporated at Albany, with a capital of $1,000,000, to conduct railway construction business and to enter into contract with railway companies for the transportation of personal property of every description. The directors are John L. Wells, Lewis B. Grant, Ashley T. Cole, William J. Bagnall and Charles T. Lark. President Winter, of the Brooklyn Rapid Transit, explains that the corporation is a small private concern to operate as a branch of the Brooklyn Rapid Transit system. Its organization was the result of the Brooklyn Rapid Transit taking over the ash collecting contracts held by Milton H. Kennedy some time ago. It was deemed advisable to have a corporation organized to do this work.

FELICITY, OHIO.—The Felicity & Bethel Railroad Company, capital stock $50,000, has been incorporated by Frank Scott. S. F. Kennedy, J. W. Hayden, J. C. Gunnings and W. A. Gregg, of Felicity.

ZANESVILLE, OHIO.—A movement is said to be on foot whereby Tucker, Anthony & Company, of Boston, will obtain control of the property of the Zanesville Railway, Light & Power Company. The Columbus, Newark & Zanesville Railway, which is owned by the Boston people, will soon be completed into Zanesville, and the local system could be consolidated with the interurban line to considerable advantage.

UNION, ORE.—A franchise to extend an electric railway system from this city to Hot Lake. Cove and other nearby cities will be asked for in the near future by T. H. Crawford. The estimated cost of the contemplated extension is $60,000.

CHESTER, PA.—The merger of the Wilmington & New Castle Electric Railway Company and the New Castle & Delaware City Railway Company into the Wilmington, New Castle & Southern Railway Company will soon be effected and a charter applied for. It is reported that the new company and the Middletown & Odessa Railway Company are negotiating for the construction of a line from Delaware City to Odessa, connecting the two lines.

PROVIDENCE, R. I.—It is intended to amend the charter of the Valley Falls & Franklin Street Railway Company, by giving the company authority to furnish and sell electricity for lighting, heating and power.

SALT LAKE CITY, UTAH.—A contract which involves the uniting of Salt Lake and Ogden by an electric railway system has been signed by Simon Bamberger, of this city, and J. J. Burns. At Farmington, a power plant will be established at an estimated cost of $115,000. By the terms of the contract the capital stock of Mr. Bamberger's road which runs as far as Farmington will be increased from $800,000 to $1,000,000 and bonds to the amount of $1,000,000 will be issued and sold, although Burns and Bamberger will retain control.

BARABOO, WIS.—William J. Bell, for many years manager of the Baraboo Telephone Company, is endeavoring to interest the business men of Portage in building an electric railway from that city to Grand Rapids. He is backed by Chicago capitalists.

TORONTO, ONT.—At the annual meeting of the Toronto Street Railway Company, held Jan. 20, reports of directors stated that gross earnings for the year as $2,172,089, an increase of $337,179 over the gross earnings of the previous year. The company's net earnings were $971,264, an increase of 18.5 per cent. Out of the net profits there have been declared four quarterly dividends, amounting to $326,548. After deducting permanent charges paid to city, and having transferred $50,000 to contingent accounts, there remains a surplus of $180,628. There has been expended for the general purposes of the company and charged to capital account, $379,615. The present officers and directors were re-elected, with the exception of James Ross, Montreal, resigned, who is succeeded by J. C. Grace.

New Industrial Companies.

THE W. & B. ELECTRIC SAND-BOX COMPANY, of Philadelphia, has been incorporated in Delaware to manufacture the Whiting & Bacon electric sand-box. The capital stock is $75,000.

THE INTERNATIONAL POWER COMPANY has been incorporated in the District of Columbia, with a capital stock of $5,000,000, by A. A. Connally, R. S. Donaldson and E. W. McCormick.

THE ELECTRIC BATTERY COMPOUND COMPANY, of St. Louis, Mo., has filed articles of incorporation. The capital stock, full paid, is $100,000, and the stockholders are G. W. Greener and Frank M. Holmes, Geo. W. Holmes, Wm. Conway, R. W. Hebard and R. H. Stevens.

THE BINNIE ELECTRIC DRILL & MACHINERY COMPANY, of Fairfield township, Westmoreland County, Pa., has been chartered with a capital stock of $10,000. Among the directors are Robert Binnie, sr., and Robert Binnie, jr.

THE SHANAHAN TROLLEY SPECIALTY COMPANY, of Little Falls, N. Y., has been incorporated with a capital of $50,000. The directors are T. B. Shanahan and J. N. Shanahan, of Gloversville, and H. P. Snyder, of Little Falls.

THE PIEDMONT CONSTRUCTION COMPANY, Indianapolis, Ind., has incorporated for the purpose of promoting, financing, constructing, equipping and operating street and interurban railways and electric plants. The capital stock is $75,000. The principal office will be in Indianapolis. Joseph Little, Jas. F. Wilson and G. E. Coghlin are the incorporators.

THE WELLS MANUFACTURING & SUPPLY COMPANY, of Indianapolis, Ind., has incorporated with a capital stock of $25,000. The company will manufacture supplies for steam and electric railways, electric lighting, telephone and telegraph companies and for contractors and builders. A. H. Wells, B. W. Forkner and E. G. Storms are directors.

THE OVERLAND & MARINE TELEGRAPH COMPANY of New York City has been incorporated to conduct a business of wireless telegraphy, and to manufacture telegraph apparatus. The capital stock is $100,000, and the directors are John W. Chapman, W. R. Sainsbury, H. R. Dennis, J. Norris Miller, Jesse W. Tobey and Harry J. Peel, of New York City.

Legal.

CONSOLIDATION IN ST. LOUIS.—The Union Electric Light & Power and Motor Edison Company's motion before Judge Ryan, in St. Louis, to strike out the amended petition in the case of Ruf, which held that the consolidation was contrary to law, has been decided in favor of the plaintiff. The decision is considered of great importance.

NEW YORK PIPE GALLERIES.—The New York Supreme Court, Justice Fitzgerald, has issued an injunction, upon application of J. Rhinelander Dillon, restraining the President of the Borough of Manhattan from opening bids, or taking any steps toward making a contract for the construction of pipe galleries to carry gas and water pipes and telegraphs, telephone and electric wires in the rapid transit subway in Broadway, between Fulton and Morris Streets. Justice Fitzgerald holds that the Commissioner of Water Supply, Gas and Electricity has control of these matters.

TELEPHONE LINES AND ELECTRIC RAILWAYS.—Judge Artman, of the Boone County Circuit Court at Lebanon, Ind., has just rendered a decision in a case involving the superior rights of telephone and electric railway companies. The New Long Distance Telephone Company, of Indianapolis, complained of Townsend Reed & Co., builders of the Northwestern Traction line, and asked that the latter be enjoined from interfering with its wires. Judge Artman denied the writ and held that when a traction company has to string its trolley wires in a certain way, telephone companies are required to change their wires to conform thereto. A telephone company cannot enjoin a traction company from thus interfering with its wires, but may recover from the traction company by a suit at law, the expense incurred by the enforced change of wires to conform to those of the electric line. This is the first ruling in the state on the direct question. Similar suits have been brought but were compromised before reaching trial.

THE EVANSVILLE, IND., TELEPHONE LITIGATION.—The litigation between the Cumberland Telephone Company and the City of Evansville has raised a question of great interest and much concern. The decision of the United States Court is that the Evansville Telephone Exchange has no right to transfer its franchise to the Cumberland Telephone Company without a specific provision for such transfer, although the franchise was granted the Evansville Telephone Exchange, its successors and assigns, and contains no provision that prohibited the transfer. The court holds that there is nothing valid in the claims of the company and no reason why the city should not remove its poles and wires. The company, however, has filed an appeal bond and contends that the higher courts will not fail to take an entirely different view. A large number of public utility corporations are doing business under purchased rights and it is a question of much concern whether the law protects them in case of transfer without specific authority.

TELEPHONE RENTALS.—The Indiana Supreme Court has affirmed the lower court decision refusing Arthur B. Irvin the statutory penalties he demanded from the Rushville Co-operative Telephone Company for its refusal to connect him with other subscribers, while his telephone bill was unpaid. Irvin, who is a lawyer, refused to pay on the ground that the company owed him a sum of money in excess of the bill on a claim assigned to him by one of his clients who had worked for the company. He claimed a set off and also that he was discriminated against, contrary to the statute. It was shown that thirty-five other subscribers were also behind in their rents, but were being served at the time Irvin was disconnected. The court held that his positive refusal to pay except by setting off the bill for labor against the unpaid rent justified the company in its treatment of him. The company was not bound to take unpaid labor claims in satisfaction of telephone rentals. Irvin had a right to sue on his claim but could not force a set off in an action for statutory penalties. Irvin sued for ten penalties of $100 each for ten refusals to connect his telephone.

TROLLEY TRANSFERS.—The New York State Court of Appeals has dismissed the appeal of James S. Lehmaier from a decision of the lower courts denying him a mandamus to compel the Interurban Street Railway Company of New York to give free transfers at Eighth Avenue and One Hundred and Twenty-fifth Street. Justice O'Brien, writing the opinion, declares that this is not the proper remedy, and suggests that the statute provides a penalty of $50 in favor of any individual who has been refused a transfer where one should legally be issued, and that in addition he may institute an action for damages to which he may have been subjected in consequence. In addition, Justice O'Brien says, the Attorney General is authorized to bring action to vacate the charter of any railroad company that violates the law, and a refusal to give transfers in certain cases would doubtless bring a corporation within the scope of that statute. Provision is also made, it is added, by the law for the investigation by the Railroad Commissioners of complaints of neglect of duty by railroad corporations, and their recommendation is enforceable by mandamus. A mandamus, it is held, is not the proper remedy until after action by the Commissioners.

POWER SUIT FOR $300,000.—Alleging that the Toluca Light & Power Company of Toluca, Mexico, has fraudulently misappropriated $80,000 in money and securities, which are the rightful property of Alexander Potter and William Tuteur, mining engineers of New York City, Mr. Potter and Mr. Tuteur have begun suit in the New York City Supreme Court here for the recovery of that amount. It is charged that the company has violated its agreement to transfer $50,000 in securities and $30,000 in money to the engineers as a return for their obtaining for the company certain large contracts in and near Toluca, a city of about 12,000 population, situated about 50 miles west of the City of Mexico. The Toluca Electric Light & Power Company was organized by Clinton L. Rossiter, formerly President of the Brooklyn Rapid Transit Company, last Spring. Mr. Rossiter had visited Mexico and obtained valuable concessions from the Government for the enterprise, and when he returned to New York he incorporated the company under the laws of this State. J. Aspinwall Hodge is counsel for Mr. Potter, who has an office at 143 Liberty Street, this city. Mr. Tuteur is in Mexico at the present time. Issues have been joined in the suit, and it is expected that it will be placed on the calendar within a month.

PASSENGERS FEET BURNED.—In a recent New York decision, it has been held by the Third Appellate Division, in the case of Mary Powell against the Hudson Valley Railway Company, that evidence that, owing to the overcrowded condition of a street car, the plate above one of the wheels of the car was pressed down upon such wheel, and that the resulting friction heated the plate to such an extent that a passenger who was standing thereon, there being no vacant seats, had her shoes and her feet and her dress burned, is sufficient to raise a presumption that the street railway company did not perform the duty incumbent upon it of using the utmost diligence and care for the protection of its passengers. In answer to questions by the defendant's counsel, an expert for the injured passenger admitted that the injuries to her nervous system were due wholly to shock caused by the burning, and not to the physical burn inself. It was therefore asserted that no physical injury was connected with the plaintiff's nervous, condition. Justice Smith, for the court, said that while the Court of Appeals has held that no recovery can be had for injuries sustained by fright occasioned by the negligence of another, where there is no immediate personal injury, our courts have never gone so far as to hold that where there is a physical injury for which a party is legally responsible that that party is not responsible for any damages which follow from the shock or fright incident thereto.

TROLLEYS VS. STEAM.—The encroachments of parallel electric roads upon the steam roads, and the determination of the latter to conserve their interests in this respect, are reflected in two cases now on argument in the Appellate Division at Albany, N. Y. One is that of the people ex rel. New York Central and Hudson River Railroad Co. vs. the State Railroad Commissioners and the Rochester, Syracuse and Eastern Railroad Co., the other that of the people ex rel. New York Central and Hudson River Railroad Co. vs. the State Railroad Commissioners and the Monroe County Electric Belt Line Co. In the first case the relator seeks to review by writ of certiorari the determination of the Railroad Commissioners that public convenience and a necessity require the construction and operation of an electric railroad between Syracuse and Rochester. The Commissioners granted a certificate on Aug. 28, 1902. The New York Central claims that there is no necessity for such a road, and that the Central now serves all of the villages in the applicant's territory. In the second case the proceeding is similar. The electric road proposes to build an electric railway commencing at the eastern limit of the city and running thence to Pittsford, Fairport, Despatch, and back to the eastern limit of Rochester, a distance of twenty miles. The Central makes the same claim in this case, that public convenience does not require such a belt line, and that the territory is now served, not only by the Central, but by two trolley lines now in operation.

PERSONAL.

E. O. SESSIONS.

MR. E. O. SESSIONS has been appointed engineer of the western sales office of the Stanley Electric Mfg. Company, with headquarters at Chicago. He has just completed the installation of three 3500-kw generators for the New York Edison Company. During the past summer, Mr. Sessions was actively engaged on the engineering work connected with the installation of Stanley sub-stations of the Cleveland and Southwestern Traction Company. A Kentuckian by birth, Mr. Sessions received his education in the public and high schools of Louisville, and by private instruction at Boston. This was further supplemented by post-graduate work at the Ecole de Polytechnique at Paris and, from a practical standpoint, in the testing laboratories of the old Thomson-Houston Company at Lynn, Mass. This was an excellent preparation for the important work of which he has had charge in the last few years. His quick perception, aggressive spirit and pleasing personality combined with his engineering knowledge and executive ability have stood him in good stead under many trying conditions. Mr. Sessions' electrical career began in 1888 in the early days of the electrical industry. His professional career includes his connection with the old Thomson-Houston Company, as already noted; the superintendency of the electrical properties of Mr. Frank Jones, the capitalist of New England, with whom he was connected for four years; engineer for the General Electric Company and later for the Stanley Electric Mfg. Company. It will be recalled that he was resident engineer for the latter at Sault Ste. Marie, Mich., in connection with the installation of the immense power plant of the Michigan Lake Superior Power Company. He has also acted as consulting engineer for Mr. W. S. Stratton, the well-known Cripple Creek magnate, in connection with the design of the power plant and betterments of the street railway system at Colorado Springs, Colo. In fact, Mr. Sessions has installed plants in all quarters of the globe. These have included in both the railway, lighting and power field, not only steam power plants, but turbo-electrical installations as well, the latter including the second largest one in the world. He has given considerable attention to high tension work, having installed several of the most important high tension transmissions. Mr. Sessions furthermore has frequently been called in to present reports on the physical and financial condition of properties.

MR. HORACE F. HARDY has succeeded Mr. John H. Glade as secretary of the South Side Elevated Railroad of Chicago.

REAR-ADMIRAL MELVILLE, U. S. N., has sailed for Europe to study steam turbine machinery, particularly for use in the new 4000-ton scout ships of the navy.

MR. ARTHUR WARREN, who created and organized the Westinghouse Companies' Publishing Department, and has managed it from the beginning, resigned his position on Feb. 1.

MR. CARL HERRING has recently been elected president of the Engineers' Club of Philadelphia. That important organization will find him an executive of great force and ability, as proved by his record as president of the American Institute of Electrical Engineers.

MR. FRANK C. PERKINS has carried on for six years a school for teaching electricity at Buffalo, N. Y., known as the Cataract Electrical School, and has lately developed its field considerably.

MR. GEORGE H. WATSON has resigned the presidency of the Northern Engineering Company, incorporated. Prior to associating himself with that concern he was connected with H. B. Coho & Company. His present location is Paterson, N. J.

MR. F. PEARSON, vice-president and consulting engineer of the Mexican Light & Power Company, Limited, has left New York for the Southern Republic, in order to inspect the progress made in the construction of the company's extensive power transmission system.

MR. FRED D. SAMPSON, manager and engineer of the Charlotte Electric Railway, Light & Power Company, of Charlotte, N. C., has resigned and is now associated with the D. A. Tompkins Company, engineers, of Charlotte, N. C., in the capacity of electrical engineer.

MR. P. SANDOVAL, of P. Sandoval & Company, of Nogales, State of Sonora, Mexico, is now in New York. The Sandoval people are largely interested in mines in Sonora. Mr. Sandoval is expected to place some fair sized contracts for electrical mining equipment while here. He is a guest at the Fifth Avenue Hotel.

NORMAN G. KENAN.

MR. NORMAN G. KENAN, who was recently elected president of the Cincinnati Gas & Electric Company, is a man of most interesting career and personality, and may be said to have been connected with illuminating interests from the very beginning. He was born in Boston, Mass., December 28, 1849, and at the age of eight went with his parents to Cloverport, Ky., where his father engaged in the manufacture of oil from cannel coal. A little later the senior Kenan moved to Cincinnati and became connected as engineer with the Gas Company, dying of cholera in 1866. This sad event left the family without resources, but young Norman immediately proceeded to provide for his mother and her five other children by selling cigars in a restaurant. This he soon abandoned to become a conductor on one of the street car lines. Every spare moment of his time, however, was given to study and to night school, while his courtesy and steadiness attracted the attention of many of the passengers on his car. One of these was President Miller of the Gas Company, through whom he was given the position of time-keeper at the West End works with which his father had once been connected. He was rapidly promoted and in 1873 became chief clerk of both the West and East End works. During all this time he was studying gas manufacture with the object of becoming an expert, and so impressed the management of the company with his abilities that in 1884 he was made superintendent of the West End works. In 1887 he became general superintendent of all the works and three years later was appointed assistant to the president, at which time he had supervision of the construction of the first electric light plant erected by the old Gas Company. In 1892 Mr. Kenan was elected vice-president of the company and has now risen by sheer merit and force of character to the head of the concern, which is one of the largest gas and electric lighting systems in the whole country. Under Mr. Kenan's management the business of the company has increased far beyond the expectations of the directors, and the confidence of his associates in him is shown in the fact that when elected to the presidency he was given power to select his own successor as vice-president.

MR. WILLIAM CURRIE has resigned his position as engineer of the Chicago office of the Stanley Electric Mfg. Co. to look after his private interests at Montreal. Mr. Currie for many years was assistant to Mr. C. C. Chesney. His many friends will regret to hear of his leaving the electrical field to engage in private business.

MR. J. ALLEN HEANY, of York, Pa., to whose novel asbestos insulated wires we have lately drawn attention, wrote recently a strong letter to the newspapers on the Chicago theatre fire and in favor of better insulation, comparing with concrete and steel in the safety given to buildings against sudden and disastrous conflagration.

MESSRS. OTTO BLATHY, Max Dery and Prof. Charles Zipernowsky have been elected "members of honor" of the Hungarian Electrical Society of Buda Pest, in token of their distinguished services to electricity. The certificates of election were handed to them by a deputation of ten members. The honor followed the reading of a paper by Mr. Alex. Wolf on "A Chapter in the History of Electrotechnics in Hungary."

MR. H. S. WAITE, general manager of the Case Mfg. Company, of Columbus, Ohio, is now on a visit to New York. He reports that business is flourishing in his section and that the Case plant has sufficient orders in hand to keep it busily engaged for the next four or five months. Mr. Waite is making his headquarters at the local offices of the Case Company in the Singer Building. He expects to leave about the middle of next week.

DR. JULIO VINGUECHERE, a South American scientist and mining expert, has been in Schenectady to inspect some recent electrical machinery and appliances to be used in the government mines of Peru. The doctor has spent many years in the development of mines in the Cordilleras of the Andes and believes that the use of electrical machinery is the only true solution of the development of the wealth in the mines now unworked because of the cost of operation.

MR. EUGENIO DAVERI, for some ten years manager of the construction department of the Italian Edison Company, of Milan, has resigned and has taken up the agency of foreign manufacturers as selling representative. He will be glad to hear from American manufacturers of trolley cars, and electrical apparatus in general. He can be addressed care of the Societa Edison, 6. Via Lecco, Milan, Italy.

MR. CHARLES FENWICK, of Fenwick Freres & Company, of Paris, one of the largest handlers of American machine tools, etc., in Continental Europe, has sailed for the other side, after a brief sojourn in the States. He left behind him some fair-sized orders with the Brown & Sharpe Mfg. Company and with the Pratt & Whitney branch of the Niles-Bement-Pond Company, 136 Liberty Street, New York.

MR. C. G. Y. KING, M. E., member of the engineering staff of the Chicago Edison Company, is to lecture before the General Electric Agents, etc., in New York City, on February 17, on the "Erection of a 5000-k.w. Steam Turbine," with some 70 slides by way of illustration. Mr. King is a veteran and accomplished central station man.

MR. CHARLES J. GLIDDEN, the well-known telephonist and now equally widely known in the automobile field, lectured last week before the Automobile Club of America, on "Thirteen Thousand Nine Hundred and Seventy-five Miles Automobile Drive in Fifteen European Countries and Across the Arctic Circle." It was a great lecture, profusely illustrated by lantern slides. Mr. Glidden has kindly consented to repeat it for charitable purposes in New England and elsewhere.

MR. WILLIAM MACKENZIE, for several years traffic manager of the Mexican Gulf Railway and who is now interested in some water powers located in the vicinity of Mexico City, is now in New York for the purpose of making financial arrangements which will permit of the construction of an hydraulic plant capable of developing about 7000 horse-power and situated about 50 miles from the Mexican capital. He is at the Hotel Imperial and at Room 1406 Broad Exchange Building.

MR. OSCAR T. CROSBY, the electrical engineer and explorer, has returned to Paris from a trip to Central Asia, where he explored almost inaccessible parts of Turkestan and Thibet. On his way to Thibet Mr. Crosby skirted Afghanistan, visited Chinese Turkestan, and later, traversed Kashmir and the Karakorum caravan route, probably one of the most difficult used by human beings to India. It will be remembered that Mr. Crosby in 1900 explored by way of Abyssinia unknown regions of the upper Nile. He is expected in New York toward the end of this month.

MR. WALTER W. WHEATLY, general manager of the Street Railway Department of the Public Service Corporation and of the street railway companies controlled by that corporation in New Jersey has resigned, and resulting changes in the management have been announced by Thomas N. McCarter, president of the corporation. The resignation has been accepted, and took effect Feb. 1. The practical operation of the system hereafter will be under the personal direction of Albert H. Stanley as general superintendent. He has just come from Detroit, where he held a similar position. Mr. Wheatly has been doing splendid work, but the public needed a scapegoat, on account of its impatience over the necessarily slow welding together of the unrelated parts of the system. And then the record winter intensified the situation.

THE ENGINEERS' CLUB at its recent annual meeting gave marked recognition to the growing strength of electrical men in the club, already one of the foremost in New York City. Mr. J. C. Chamberlain, a well-known electrical engineer, was elected a trustee and made also chairman of the House Committee. Mr. M. G. Starrett, of the Interurban and Metropolitan Street Railway Companies, was elected a trustee to serve until 1907. Mr. T. C. Martin, already member of the board, was made second vice-president and put on the membership committee. The club's new president is Mr. W. H. Fletcher, a man of strong personality and qualities of leadership. The financial condition of the club is very sound and with a waiting list of nearly 200, many of whom have been up for over a year, there was a unanimous vote for the constitutional amendment raising the limit from 1,000 to 1,200.

MR. C. E. BROWN has resigned his position as electrical engineer for the Canadian General Electric Co., having been appointed by the Canadian Government as electrical engineer of the commission recently established to investigate the electro-thermic processes of manufacturing iron and steel in Europe. All who know Mr. Brown, and know of his work, feel that the Dominion Government is exceptionally fortunate in being represented by so thorough and practical a man. Mr. Brown is a native of Iowa and was graduated with honors from the University of that State. He later took up post-graduate work at Cornell University. After that he became connected with the General Electric Co., with which he was connected for four years as electrical engineer. Electrical manufacturing then took on great strides in Canada, and Mr. Brown went to Peterboro, Ontario, where he has been associated with the Canadian General Electric Co. for the last five years.

DR. J. L. BORSCH, of Philadelphia, has testified in a recent trolley personal damage suit that he has restored a man's sight by means of radium after every other means had failed. That the man has his sight again is a fact, as he was in the court room with apparently good vision and a prominent physician, who after treating him himself referred him to Dr. Borsch, testified to the man's condition before being treated by the radium expert. Dr. Borsch says: "In Sharpe's case, there were still remaining some normal cells—the man was not entirely blind, as stated—and these I stimulated into greater activity by use of the radium. Gradually I noticed a change in the man's condition and found that the stimulation had resulted in producing an amount of activity in the remaining cells not affected, equal or very near, at least, to the combined activity of good and bad before the injury. I applied this little twisted glass affair to the eye for about five minutes at a time, bandaging it very tightly. The radium used was not in excess of 20,000 activity."

PROF. W. S. GOLDSBOROUGH, of the Department of Electricity at the St. Louis Exposition, gave the New York Electrical Society last week a most admirable lecture on electricity at modern expositions and at the Louisiana Purchase Exposition in particular. The lecture was profusely accompanied by lantern slides, and to these the discourse was adjusted, the completeness of the series being shown by the fact that over 100 were thrown on the screen. Prof. Goldsborough brought out very clearly the fact that electricity lighting had made possible the modern world's fair with its large night attendance and its spectacular effects. At the same time, he showed that of later years the electric motor had effected changes in the daylight plan and had contributed largely to the increase in the number of "live" operating exhibits. Prof. Goldsborough, in passing, took occasion to pay a tribute to the memory of the late Luther Stieringer as a pioneer in exposition lighting. He touched also upon the subject of international electrical congresses, and in allusion to the work now being done under Prof. Elihu Thomson, an excellent portrait of whom he showed, said he believed that the St. Louis Congress would be one of the most important in the series. President Carty, in closing the meeting, suggested happily that President Loubet of France ought to be invited to open by cable the Exposition, and after a felicitous speech by Mr. C. O. Mailloux, the society voted its hearty approval of the idea.

EDUCATIONAL.

DRAFTING.—The General Electric Company has established a Drafting Room Apprenticeship Course, to which young men who are able to pass a satisfactory examination in arithmetic are eligible. The course is intended to fit applicants for drafting room positions. Further information can be obtained by application to Mr. J. W. Upp, engineer in charge of drafting room, General Electric Company, Schenectady, N. Y.

OBITUARY.

MR. A. G. BOWERS.—We regret to note the death of this well-known man, Mr. Alfred Graham Bowers was born at Port Huron on March 31, 1870. As a young man he entered the employ of the Bell Telephone Company, at Detroit, which position he subsequently left to enter the printing business at Montreal and while there he pursued the study of electricity. Returning to Port Huron, he entered the employ of Mr. D. J. Stevenson, an electrical contractor at Port Huron, where he gained considerable experience in general wiring and construction work. He was subsequently in the employ of Mr. E. C. Lombard, a construction contractor at Jackson, Mich.; was superintendent of the Whitehall, Mich., electric light plant. Leaving Whitehall he took up sales work and was successively identified with the Bryan-Marsh Electric Company as its Iowa and Minnesota representative, and the Ewing-Merkle Company of St. Louis, in the same territory. In the fall of 1903 he entered the employ of the Fort Wayne Electric Works as sales representative in Iowa, which position he held up to the time of his death. He died at Des Moines, Iowa, on Jan. 21, of pneumonia, after a few days' illness. In 1901 he married Miss Lillian Scoville, of Battle Creek, Mich., who survives him. His mother, Mrs. A. Bowers, and several married sisters live at Cass City, Mich. Mr. Bowers was widely known among the central station men and representatives of other electrical supply house in his territory, among whom he had many warm admirers, who will miss his genial and sincere friendship. Mr. Bowers was a member of the Knights of Maccabees and the United Commercial Travelers' Association. The funeral was held at Port Huron, Mich., Jan. 23.

MR. W. C. WHITNEY.—We note this week with deep regret the death, following an operation for appendicitis, of Mr. W. C. Whitney, formerly Secretary of the Navy under President Cleveland, and the great reorganizer and consolidator of the street railway system of New York City. Mr. Whitney, who was 64 years of age, came first into prominence as corporation counsel for New York City and soon rose to a prominence in Democratic counsels which he maintained to the time of his death. It was not until after his splendid work in creating the modern American navy that he turned his attention to traction, and then with the aid of Messrs. H. H. Vreeland and Daniel Lamont he soon built up the network which now constitutes the greatest electric street railway system in the world, under the names of the Metropolitan and Interurban Street Railway Companies. In this manner, while developing conduit work, he became interested in electricity in general, and had a large share in the promotion of electrical automobilism through the Electric Vehicle Company and its sub-companies. In this work he continued to take a deep interest to the last. A year or two ago he also became interested in the Stanley Electric Mfg. Company and is understood to have held a large ownership until its absorption by the General Electric Company. Of Mr. Whitney's fame as a sportsman and public spirited associate in many movements it is unnecessary to remind our readers. It is likely that his son, Mr. H. P. Whitney, will continue to represent his interests in the important field of work and play referred to above, including also his interests in the Consolidated Gas Company.

Trade Notes.

WHITEHEAD MACHINERY CO., of Davenport, Ia., notes its removal to the third floor of the Hagehoeck Building, West Second St., in that city.

MOORE ELECTRICAL CO., 52 Lawrence St., Newark, N. J., has issued a neat pamphlet in regard to its vacuum tube system of lighting. It is not illustrated.

ELECTRICAL SUPPLIES.—Mr. W. A. Hawkins, of Mt. Jackson, Va., has moved to Hagerstown, Md., with the object of opening a general electrical supply store, as well as to do house wiring, telephone work, etc.

SHEPHERD ENGINEERING COMPANY, of Franklin, Pa., has just opened a western office in the First National Bank Building, Chicago, of which Mr. L. J. Highland will be in charge, with the object of attending promptly to orders and inquiries for Shepherd engines in that part of the country.

QUEEN & COMPANY, INC., of Philadelphia, have issued a handsome and instructive circular celebrating the fifty years of their existence, 1853-1903. It gives a synopsis of the history of the house, illustrates some of its leading apparatus, etc., and gives views also of its laboratories, factories, etc.

THE WARD LEONARD ELECTRIC COMPANY reports a large increase in business in field rheostats during the last two weeks. It believes that the slightly dull season which seemed to have come over the electrical trade must have passed. They are about to issue new circulars covering theatre dimmers, speed controllers, etc.

HALLER MACHINE CO., of Chicago, Ill., 127-129 Fulton Street, has issued a handsome circular in regard to its metal letters for electric signs, complete electric signs, and other electrical specialties, novelties, etc. It gives full details and prices and should be seen by every one of our central station and isolated plant readers.

R. THOMAS & SONS CO., of East Liverpool, Ohio, has issued a neat price list and catalogue on high voltage transmission line porcelain insulators, all of which have been designed with great care and equal resultant success. The catalogue and list should be seen. It is a handsome publication and deals with meritorious appliances.

SMITH & HEMENWAY CO., of 296 Broadway, New York City, has completed arrangements with the Page-Storm Drop Forge Co. to handle its entire line of engineers' and drop forge wrenches. The latter concern makes a specialty of all kinds of drop forgings. The Smith & Hemenway Co. has ready a new catalogue on the subject and invites applications for it at once.

CHICAGO FUSE WIRE & MFG CO., of 358 Dearborn St., Chicago, etc., etc., has issued No. 15 of its admirable little series of catalogues and price lists. Its experience with tested fuse wire extends over 15 years, and its list now includes the latest ideas, practice and developments in that field. Special attention may be called to its "Union" fusible links, "Union" switch outlet boxes, etc.

FARWELL, OZMUN, KIRK & COMPANY, of St. Paul, Minn., one of the leading wholesale hardware firms of the northwest, have opened an electrical supply department. Mr. J. S. Webster, who has been for many years engaged in the design, sale and installation of apparatus while located in Minneapolis, has become manager of the new department and would like to have descriptive circulars and prices from all manufacturers of standard electrical supplies and specialties.

THE S. H. COUCH COMPANY, 156 Pearl Street, Boston, Mass., has issued a four-page circular, describing its "Workwell" Telephone. These telephones are put on the market at very moderate expense and the illustrations portray a good-looking pair of instruments. Included in the circular are the specifications of the instrument making good reading for people desiring telephones for communication between house and stable, or between office and shipping room, or between any two points.

PITTSBURGH TRANSFORMERS.—Mr. A. H. Mustard, 120 Liberty St., New York, sales agent for the Pittsburgh Transformer Company, recently sent out some interesting literature regarding these well known transformers. In one of the circulars it is pointed out that 85 per cent. of the people who bought Pittsburgh transformers five years ago are buying them to-day. Another circular gives illustrations of three styles of transformers, specifications of each being given. These transformers have acquired a standing due largely to their merit, but the efforts of the sales department have, of course, contributed largely to their wide use.

THE CALCULAGRAPH COMPANY has issued a little card for keeping accurate track of the regulation of the Calculagraph. This is arranged so that an entry is made on the card as to whether the Calculagraph runs fast or slow and as to the extent and affords a means for keeping tab so that the Calculagraph may be regulated exactly. Incidentally, the card is a good thing for a man to have who wishes to regulate his watch and know that it is running properly. The card, of course, merely affords an opportunity for making an entry of the variation of a watch so that the variation may be carefully noted.

WESCO SUPPLY CO.—The new price book just issued by The Wesco Supply Co., of St. Louis, covering its No. 50 Catalogue, has been sent out to all in the trade who has a No. 50 book. Anyone who has not received this catalogue can secure it by writing to the concern. In addition to the latest market prices on all articles shown in the above catalogue, the price book contains several lines of new goods, and a copy of the latest rules of the National Board of Underwriters. These rules will be found very useful as a ready reference, and the Wesco people have inserted them for the special convenience of their customers.

WIRE REELS.—Messrs. Eugene Conard & Sons, Elizabeth, N. J., manufacture reels of all sizes for wire and cable. These reels are made with special machinery of the firm's own design. The strength of reels depends much upon how the nails are clinched in the building up. This firm recognized the importance of this little detail and clinches each nail separately by hand, thus securing the strongest possible structure. The firm aims to produce the best reel possible, and many of its reels are being used by the larger wire concerns. It has ample facilities for getting out orders promptly, and can ship either by rail or water.

NATIONAL WIRE CORPORATION.—The New York offices of this important concern have been removed to Room 1103, Engineering Bldg., 114 Liberty St., with Mr. Richard C. Smith as New York sales agent, who says: "We shall be pleased to receive all inquiries at our new office, and will be prepared at all times to furnish information or to make quotations when desired. Our New Haven mills are now in full operation, producing a large variety of wire products, including wire rope, galvanized telephone and telegraph wire, wire strand, tinned and coppered market wire, bright and annealed market and stone wire, bright and coppered screw stock, tinned mattress wire, black, coppered and liquor drawn spiring wire, and a great variety of special and miscellaneous wires for the jobbing and manufacturing trade."

MR. CHARLES E. MILLER, the enterprising New York jobber of automobile and bicycle material, has leased the properties 316 and 320 North Broad St., Philadelphia, from Jan. 1. From this branch he will conduct both a wholesale and retail business. It is his intention to make elaborate improvements in this store, and make it the most attractive of its kind in the country. As there are large show windows in the front of these stores he will have an excellent opportunity to make a fine display, and he intends to treat Broad St. promenaders to an automobile show of the continuous performance order. The same energy and business acumen that have brought him such a large measure of prosperity, both in his main salesrooms at 97-101 Reade St., New York, and his retail branch at Thirty-eighth St. and Broadway, New York, will undoubtedly crown his Philadelphia enterprise with success.

THEATRE ATMOSPHERES.—The ventilation and heating of a theatre presents a problem not easily mastered by the ordinary heating engineer. In a crowded auditorium of this kind ventilation is the all-important question. It may be a simple matter to heat the building to a required temperature before the curtain rises, but to maintain a constant temperature and a pure atmosphere while the play progresses is not so easily accomplished. The heat given off from the bodies of the closely-seated audience is sufficient to raise the temperature in the house from 5 to 10 degrees during the performance. Fresh air to breathe must be supplied constantly to the occupants and the impure air must be removed. Evidently a system giving a forced circulation of air is necessary to meet those requirements. A good example of this system is the recent installation in the New Franklin Sq. Theatre, at Worcester, Mass. The heating and ventilating apparatus consists of an electrically-driven fan and heating coils, located in a corner of the basement. Fresh air is drawn from the outside and circulated through coils of steam pipes enclosed in a fire-proof casing and distributed through ducts by means of the fan to the desired parts of the theatre. There are plenum chambers under the orchestra floor and first balcony from which air is admitted through openings in the chair legs giving an even distribution throughout the house. The low velocity with which the air enters prevents annoyance from draughts. The foul air is exhausted through grills in the dome of the theatre and by means of an electric exhaust fan is discharged through the roof. The B. F. Sturtevant Company, of Boston, Mass., was the heating and ventilating engineer, and the apparatus installed is of its manufacture.

Record of Electrical Patents.

UNITED STATES PATENTS ISSUED JANUARY 26, 1904.

[Conducted by Wm. A. Rosenbaum, Patent Attorney, 140 Nassau St., N. Y.]

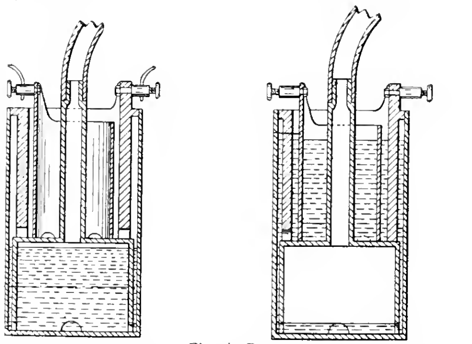
750,250. ELECTRIC BATTERY; Winfield S. Bryan, Cincinnati, Ohio. App. filed Sept. 28, 1903. An inverted cup connected by a tube with a source of air pressure, is located in the bottom of the cell and while the battery is not in use, the liquid of the cell is allowed to flow under the edges of the cup and fill it, thus covering the electrodes located above the cup; when the battery is to be put into use, air pressure drives the liquid out of the cup into the cell.

750,268. ELECTRIC SIGNALING APPARATUS; William E. Decrow, Boston, Mass. App. filed April 29, 1901. (See page 272.)

750,269. ELECTRIC SIGNALING APPARATUS; William E. Decrow, Boston, Mass. App. filed June 17, 1901. (See page 272.)

750,270. ELECTRIC SIGNALING APPARATUS; William E. Decrow, Boston, Mass. App. filed Sept. 27, 1901. (See page 272.)

750,288. RINGER; Anton M. Knudson, Chicago, Ill. App. filed June 6, 1902. (See page 272.)



750,250.—Electric Battery.

750,289. TELEGRAPH INSTRUMENT STAND; James W. Leech, Staunton, Va. App. filed Jan. 6, 1903. A stand for a telegraph instrument embodying a sounding box and reflecting board.

750,296. ELECTRIC RAILWAY SIGNAL; William V. Moak, Albany, N. Y. App. filed Dec. 8, 1902. Details.

750,309. ANNUNCIATOR; Lambert Schmidt, Weehawken, N. J. App. filed Aug. 28, 1901. The construction relates to the shutter-tripping mechanism.

750,352. OUTLET BUSHING FOR JUNCTION BOXES; Frederick W. Erickson, Boston, Mass. App. filed Oct. 5, 1903. A nut adapted to screw onto the end of the conduit carries a sheet metal flared rim for the end of the conduit.

750,361. ELECTROMETALLURGY OF IRON OR STEEL; Henri Harmet, St. Etienne, France. App. filed Sept. 30, 1901. (See page 274.)

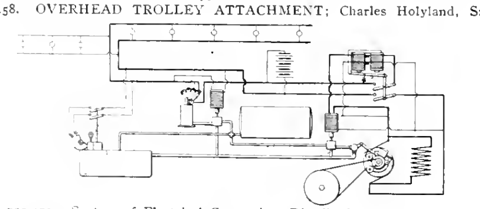
750,368. TROLLEY FOR ELECTRIC RAILWAY CARS; Charles J. Johnson, St. Louis, Mo. App. filed May 14, 1903. Details.

750,421. ELECTRIC BRAKE; George C. Anthon, Medford, Mass. App. filed Nov. 30, 1901. A liquid lock and release for the brake and means for controlling the same; also certain improvements in electro-magnetic clutches by which a brake winding drum is brought into frictional engagement with a driven axle.

750,422. ELECTRIC BRAKE; George C. Anthon, Medford, Mass. App. filed April 11, 1902. The brakes are actuated by current from a storage battey, the battery being charged by the line current, with provision also for operating the brakes from the line.

750,454. SYSTEM OF ELECTRICAL DISTRIBUTION; Josef H. Hallberg, New York, N. Y. App. filed Oct. 16, 1903. As a means for balancing the current in individual circuits of a multi-voltage system, a pair of motors having their armatures driven at the same speed and connected to supply the required voltages, and the field magnet of the motors connected so that the field of one motor will receive current from the circuit in which the armature of the opposite motor is included.

750,458. OVERHEAD TROLLEY ATTACHMENT; Charles Holyland, Sr.,



750,471.—System of Electrical Generation, Distribution and Control.

Pittsburg, Pa. App. filed June 6, 1903. Details of a device to retain the wheel on the wire.

750,471. SYSTEM OF ELECTRICAL GENERATION, DISTRIBUTION AND CONTROL; Lamar Lyndon, New York, N. Y., and Elmer A. Sperry, Cleveland, Ohio. App. filed Jan. 17, 1903. Regulating mechanism for a system of lighting in which the generator is driven from the car axle; the regulating being accomplished through a fluid actuated belt-tightener.

750,492. ELECTRIC CLOCK; Fred Schmidt, Oak Station, Pa. App. filed May 9, 1903. Details.

750,497. SYSTEM OF ELECTRICAL GENERATION, DISTRIBUTION AND CONTROL; Elmer A. Sperry, Cleveland, Ohio. App. filed Dec. 5, 1902. A modification of patent 750,471.

750,500. SYSTEM OF ELECTRICAL GENERATION, DISTRIBUTION AND CONTROL; Elmer A. Sperry, Cleveland, Ohio. App. filed July 1, 1903. Relates to the preceding system.

750,509. ELECTRICAL CONDUCTOR; William H. Wherry, Cleveland, Ohio. App. filed Nov. 3, 1902. The bond heads are welded to the rails.

750,510. PROCESS OF FORMING ELECTRICAL RAIL BONDS DIRECTLY IN PLACE ON THE RAILS; William H. Wherry, Cleveland, Ohio. App. filed Jan. 22, 1903. The process consists in applying heat to the head of the bond while it is in contact with the rail, until the latter is melted and becomes alloyed with the bond.

750,522. APPARATUS FOR BONDING RAILS; William B. Cleveland, Cleveland, Ohio. App. filed Oct. 30, 1902. A sheet metal sleeve embraces the middle portion of the bond to protect it when confined inside of the fish-plate.

750,525. TRANSFORMER; Augustine R. Everest, Lynn, Mass. App. filed Aug. 11, 1902. A transformer core made of two bowed members hinged together at one end and having engaging extensions at the other end, the coils being slipped over the members when they are open.

750,543. HEAT ALARM; Howard F. Jones, Wilson, N. C. App. filed April 13, 1903. Details.

750,549. SYSTEM OF ELECTRICAL GENERATION, DISTRIBUTION AND CONTROL; Lamar Lyndon, New York, N. Y. App. filed Jan. 22, 1903. In a train lighting system the electro-magnetic device by which the speed of the generator is controlled, is actuated by current from the battery, so that as the voltage of the battery rises in charging, the speed of the dynamo is reduced.

750,550. SYSTEM OF ELECTRICAL GENERATION, DISTRIBUTION AND CONTROL; Lamar Lyndon, New York, N. Y. App. filed July 18, 1903. Relates to the regulating devices in a train lighting system.

750,563. PROCESS OF COVERING WIRE; James C. Anderson, Jersey City, N. J. App. filed April 30, 1903. Copper ribbon is covered by making an elongated envelope of paper, then covering the envelope, inserting the ribbon and closing the envelope.

750,584. PROCESS OF ADMINISTERING ELECTRICAL VIBRATIONS; Fred H. Brown, Los Angeles, Cal. App. filed Aug. 25, 1902. Electrical impulses whose periods of vibrations are synchronous with musical vibrations, are created by causing musical sounds to vary the resistance of an electric circuit; an induced current created therefrom is administered therapeutically.

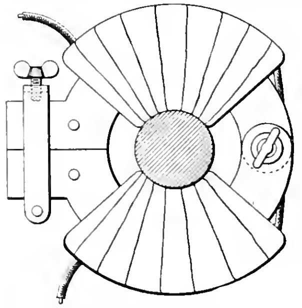
750,594. MAGNET; Henry F. Campbell, Boston, Mass. App. filed May 16, 1901. A magnet comprising parallel horseshoe-shaped bars arranged to have an air space between them and a pole piece adjustably mounted upon the lower ends of the bars.

750,646. COMBINED ELECTRICAL BATTERY RECEPTACLE AND BELL SUPPORT; William A. Harvey, Scranton, Pa. App. filed Sept. 9, 1903. Details.

750,689. PLUG FOR TELEPHONE-SWITCHBOARDS; Frank D. Pearne, Chicago, Ill. App. filed April 20, 1903. (See page 272.)

750,704. TELEPHONE SWITCHING AND SIGNALING APPARATUS; Malcolm C. Rorty, Dedham, Mass. App. filed Jan. 3, 1902. (See page 272.)

750,720. INCANDESCENT LAMP; Walter A. Springall, San Antonio, Tex. App. filed June 25, 1903. A multi-filament lamp having contacts in its



750,525.—Transformer.

neck by means of which the filaments can be successively thrown into circuit by twisting the neck in its socket.

750,722. INSULATOR; Louis Steinberger, New York, N. Y. App. filed May 25, 1903. A knob of insulating material covered by a metal casing and having an opening through which the conductor is to be threaded.

750,723. BINDING POST; Louis Steinberger, New York, N. Y. App. filed June 22, 1903. The post has two threaded portions succeeding each other and of different diameters, each one carrying its own wire clamping devices.

750,733. TROLLEY POLE; John J. Tartt, Los Angeles, Cal. App. filed March 30, 1903. An arm carrying the wheel is pivoted to the upper end of the pole and actuated by its own spring, the construction being such that vibrations of the pole will not be communicated to the arm.

750,753. ELECTRIC FURNACE; Rámon Chavarria Contardo, Sèvres, France. App. filed Aug. 24, 1900. (See page 274.)

750,765. ELECTRIC MOTOR; Thaddeus W. Heermans, Chicago, Ill. App. filed Dec. 4, 1899. Both the field magnet and armature are rotating parts, to each of which a pulley is attached and a speed-controlling device is interposed in such a manner that as the speed of one part rises, the other falls, without varying the power of the motor.

750,769. TELEPHONE-SERVICE APPARATUS; Uriah S. Jackson, Ossipee, N. H. App. filed May 31, 1902. (See page 272.)

750,770. TELEPHONE-SERVICE APPARATUS; Uriah S. Jackson, Boston, Mass. App. filed April 22, 1903. (See page 272.)

750,777. APPARATUS FOR SELECTIVE SIGNALING; Kenneth Moodie and John S. Small, Chicago, Ill. App. filed Sept. 13, 1902. A number of pairs of helices, each comprising a main circuit helix and an operating circuit helix, means for operatively neutralizing the effect of any main circuit helix by sending a current over the operating circuit, certain of the helices being relatively so arranged and so energized as not to be neutralized by an operating current which will result in neutralizing another of the helices.

750,781. SAFETY DEVICE FOR RAILWAY SERVICE; Edmund B. Powers, New York, N. Y. App. filed March 5, 1903. A projection from the locomotive is struck by an arm at the roadside and moved a certain distance to actuate a certain signal by the particular location of the arm at the roadside.

12,195. ELECTRICAL ACCUMULATOR; Chaimsonovitz Prosper Elieson and Vladimir de Bobinsky, Paris. France. App. filed Oct. 26, 1903. (See page 272.)

Electrical World and Engineer

THE CONSOLIDATION OF "THE ELECTRICAL WORLD" AND "ELECTRICAL ENGINEER."

CONTENTS.

The Institute Dinner.

The Institute annual dinner will occur just after our issue has gone to press, and we must reserve our report until next week. We are glad to know that it promises to be unusually well attended, and a brilliant and memorable success, worthy the work put upon it, and the anniversaries it celebrates. We are glad to be able to extend our congratulations to Mr. Edison and the Institute upon the founding of the first electrical medal in this country associated with his name, and hope the medal will be won by many worthy recipients who will also come in due time to make their part and mark in the electrical arts.

Manufacturing Competition.

One of the most important recent events in electro-industrial development is the new departure of the Allis-Chalmers Company, one of the great steam engineering manufacturers of the country, to whose purpose of becoming also a leading electrical manufacturer, we give publicity this week. The corporation has great resources, has recently made notable affiliations, and now has enlisted for its electrical staff some well-known men, whose names we mention. This is a move which will be watched with deep interest and may be fraught with many consequences as to the future of the art, now broadening and widening in every direction.

War in the East.

Now that war has unfortunately broken out in the Far East, it will be interesting to see what use Russia and Japan make of the modern resources of electricity as applied to warfare, both on land and on sea. The Transvaal war and the Spanish war were both rather disappointing as to the use of new devices, but we think the present struggle may furnish some lessons. The Russians have engineers with a distinct leaning to electricity, while the brave and energetic Japanese "miss no trick," in what is new and useful, whether for war or peace.

An Interesting Bit of Hydraulics.

A rather unusual variation of Eastern hydraulic practice is that reported on page 305, this week, on the Bull's Bridge power plant. This new enterprise on the Housatonic reminds one in certain ways of current Western practice, yet varies from it in some important particulars. The hydraulic developments here in the East have been evolved from the early work on the large New England rivers by a process that has been upon the whole determined by provincial canons of practice as thoroughly as has been the speech of the Yankees who have undertaken the work. Lowell, Holyoke and similar cities have furnished the impetus for the investment and the work has gone on by the sole light of their experience. The articles of the Eastern hydraulic creed may not number quite thirty-nine, but their fixity puts to shame their theological prototype. A stream with a moderate fall and plenty of water, a stone dam built for time and eternity, regardless of expense, a hewn masonry canal and tail race, vertical shaft turbines with plenty of gearing, which the owners swear wastes no power at all—and the hydraulic engineer was content with the work of his hands. There have been schismatics and heretics even in New England, however—wretches who had the temerity under stress of hard times to put in crib dams that would only last a generation or two, and backsliders who tried to wreck the foundations of the faith by objections to bevel gearing; but in the main Eastern hydraulic plants have seldom wavered in the faith save when tempted by evil-minded electricians.

In the West the pioneer in hydraulic work was the mining and irrigating engineer, bringing down to the placer diggings and to the broad acres of the valleys the melted snows of the Sierras, carrying the clear little stream a score—yes, a hundred of miles, if need be—in ditches and flumes and tunnels and inverted syphons, until he could drop it a sheer eighth of a mile or so down to the gravel banks or the sage brush deserts that turned to gardens at its touch. It was a different school from that of the East with very different lessons to be learned—but learned they were, and thoroughly. Now, here in the East we are just beginning to appreciate the situation, and as the larger powers on the older streams are taken up, to cast about for powers anywhere, with a willingness to develop them according to their needs, with little respect for tradition. And such powers as this at Bull's Bridge are the first fruits of this broader outlook. In the arrangement of the works with a long canal ending in steel pipes plunging right down upon the wheels, the situation is typically Western, even though the fall is only a beggarly hundred and twenty-five feet or so. The dam, however, is much more of a structure than is usual in Western plants and the canal follows Yankee patterns in many respects. It is something, however, to note that the dam is of rubble and concrete, a construction which is distinctly a compromise between progress and precedent. We believe in good construction, but we have here in the East much to learn as to methods of maximum economy in hydraulics. Each year is likely to see new finds among the New England and Appalachian hills and more cases for the adroit adaptation of Western methods of practice. There are a good many falls of surprisingly great head to be utilized by those far-sighted enough to pre-empt them. Most of them are relatively small, but in the present condition of electrical power transmission can be profitably developed.

The Series Wound Alternating Motor.

The specification of Mr. Lamme's alternating railway motor, printed elsewhere in this issue, is interesting as showing an entire absence of sensational features. The success which Mr. Lamme has reached is in the line of downright skill in designing, the union of a firm grasp on the practical requirements of the case with great technical facility at suiting means to ends. The motor as described is a simple series-wound structure with an immensely powerful armature, high-resistance commutator leads, and pole faces perforated longitudinally to break up cross-induction. To simplify the commutation the frequency is low, the voltage is kept moderate and the poles are fairly numerous to bring the rotative speed to the best working point as regards the armature alternations. Mr. Lamme has apparently found that first-class working conditions are attained only within rather narrow limits in the design, and in his patent certain approximate conditions of design form an essential part of the claims. We shall be particularly interested to see how far these somewhat stringent conditions may, in practice, affect the performance of the machine on direct-current circuits. One of the conspicuous advantages of the series-wound alternating motor is the fact that at least in theory the machine can be successfully operated on direct-current circuits, and so can be made available for the existing urban connections of interurban roads. If, however, the design from the standpoint of alternating current operation is rather closely limited, will the motor meet the full practical requirements of tramway work on the usual direct-current systems? This is, of course, a question of fact not to be answered offhand or from an inspection of the patent specification. It is safe to say, however, from the judgment displayed in the alternating-current design, that if a successful compromise is practicable, Mr. Lamme is fully competent to work it out.

Graphics in Power-House Location.

It is a well-known proposition in the theory of electric power transmission that the electrical center of a district is its center of gravity. That is to say, if a massless plane map of the district be prepared, and at each point of load a corresponding mass be located, at the rate of say one milligramme per ampere to be supplied, then the center of gravity of all the masses, or the position on the map at which the sum total of the masses would be equivalent to the total distribution; or, again, the point on which the map, as a rigid plane, would float horizontally, if rested on the point of a vertical needle, is the center of distribution of the system for minimum copper in radial distributing conductors, arranged for uniform current density, and for any given drop of pressure in transmission. A power house should theoretically be located at the electrical center of gravity for the greatest economy of distribution. Of course, the proposition applies to an ideal case, in which land has the same value at all parts of the district, and where no natural obstructions prevent a power house from being erected; where rights of way are all alike, and where the designing engineer can lay out a distribution system as the Russian Czar is said to have laid out the Moscow-St. Petersburg Railway—with a map, a straight-edge and a pencil. It is doubtful whether such ideal conditions of electric power house location exist even beyond the skies. They never have been reported to occur on this earth. The power house can never fall on the exact center of gravity of the system. Moreover, the distribution lines are always subject to some conditions of dissymmetry. Again, the prospective loads are never predeterminable with mathematical accuracy. They are always open to a certain range of doubt, and estimation must take the place of computation to a greater or less degree. Consequently, the center-of-distribution law has about as many restrictions, qualifications and reservations, in practice, as the Kelvin law of the most economical size of conductor to transmit a given power. In theory, these laws are rigid and adamantine. In practice they are made so tortuous and flexible that their own authors would sometimes never recognize them. Nevertheless, the engineer should be familiar with these propositions. He should instinctively do obeisance to the law of the electrical distribution center, even when his mind is devoted to the numerous details of land value, water supply, coal supply, rights of way and wrongs of way.

If, however, the center-of-gravity law is powerless, in practice, to assign the most economical center of distribution from the business man's standpoint, it is at least capable of declaring when the center of distribution ought not to be located from the conductor cost standpoint. It is well, at least, to be able to determine, as closely as the load estimates will permit, where the center of distribution lies, in order to compare the location of the economy council with the location of the economy of conductor, the council being composed of representatives of land, fuel, transport, property rights and president's proclivities, along with Mr. Copper Conductor. The ordinary method of finding the center of gravity of a district is to mark off the loads on the map, then to project those loads orthogonally on any pair of co-ordinate axes, such as the edges of the map, to compute the center of gravity of these loads, on each edge separately, and to mark off the center on the map at the intersection of the co-ordinates of the centers of gravity on the edges. This process requires two arithmetical processes to be pursued, for determining the centers of gravity on the two edges respectively. The article by Mr. S. Diamant on page 311 offers an ingenious method of solution for these two arithmetical problems without resorting to arithmetic; that is, by purely graphical methods. To some persons graphical methods are specially welcome. Isaac Newton's genius showed itself in graphics most particularly. Other persons prefer arithmetic to the pencil and protractor. But whichever method may be preferred, the graphical problem will always have interest. Mr. Diamant projects his loads upon the co-ordinate axes in the usual way, and then makes a pair of auxiliary diagrams. These diagrams lead to certain angular relations between lines definitely related to the lines of load. By working with these angles on the edges of the map, the two centers of gravity are arrived at without computation. Whether this geometrical solution is known in mechanical graphics we are not informed; but the geometrical proposition seems to be new in electric technology.

RADIATIONS EMITTED BY A RIGHI VIBRATOR.

In the last number of the *Physical Review* an interesting series of measurements is reported by Messrs. Willard and Woodman on the radiations emitted by a Righi vibrator. A Righi vibrator consists essentially of four metal balls in a line, with three spark-gaps between them. The middle spark-gap is usually in oil. The balls are ordinarily small, like large-sized marbles, and the waves that such a vibrator emits when the extreme balls are suddenly electrified or discharged, are about as short as can be conveniently produced. Sometimes the inside pair of balls are of larger diameter than the outside pair, and sometimes only three balls are used, one big one in the middle and two little ones, at opposite ends of a diameter. There is a great difference of opinion as to the nature of the waves emitted when the electric system is struck. Some contend that the system emits all wave lengths, in a continuous spectrum, and that the particular waves which affect the resonator are selectively determined by the dimensions of the latter. Others believe that the vibrator emits waves of definite length—that is to say, of a length which has a definite geometrical relation to the size of the vibrator—but that, owing to the highly damped nature of the vibrations, or their rapid diminution and decay, the wave lengths appear to cover a wide range. One school supports the theory of a continuous spectrum; the other supports the theory of a simple spectrum with a line or lines like a gas spectrum.

When the vibrator attains a considerable length, as in the antennæ of wireless telegraphy, the theory of wireless telegraphy has long pointed to the existence of a fundamental wave, of four times the height of the mast, or twice the length of the antenna with its "image" below the ground. Upon this fundamental should exist an indefinite number of harmonics like those of an excited musical string. The number and prominence of the harmonics depend upon the particular detail conditions of excitation. In general, the bulk of the energy is carried by the fundamental waves. If Righi vibrator radiations resemble wireless antenna vibrations, then the line spectrum theory is favored rather than the continuous spectrum theory, assuming that there will be a plurality of lines, in harmonic or simple multiple relationship. The Righi vibrator is, however, not the simplest type of vibrator, and it seems possible for some complications to exist in its vibratory system. The measurements of Messrs. Willard and Woodman show that the waves emitted had pronounced fundamental wave lengths and also distinct harmonics. At the same time the measurements show that the dimensions of the resonator materially affect the received energy. So rapid is the damping of the waves emitted by the vibrator that the waves may almost be regarded as single impulses, with an insignificant trail. This simple impulse, striking the resonator, sets the latter in vibration according to its own frequency and wave length. Consequently, the tuning of the vibrator to the resonator has much less effect than if the resonator emitted a continuous train of waves.

THE SPIRIT OF TECHNICAL EDUCATION.

Some time since, in commenting on President Butler's proposition for a two-year college course, we expressed the opinion that so far as success in technical callings was concerned, education ought to be broadened rather than narrowed. So far as the mere acquisition of facts is concerned, systematic perusal of a modern technical journal will furnish more raw material than the average course of instruction in a technical school, but we would be the last to insinuate that the former renders the latter unnecessary. What the successful engineer wants is power and facility in using the raw material that he finds at hand, and this can be acquired only by a wide and thorough intellectual training. Its scope and character is of far less importance than its thoroughness. We do not wish to make invidious comparisons between institutions, but we know of none which have furnished a large number of brilliant engineers in various departments compared with the total number of graduates than the United States Military and Naval Academies. These men were trained not in the so-called practical details of modern engineering, but in the art of war, but so trained that their mental and physical powers were under full command for what they might be worth. It is the foundations which count, and the wider and deeper these are laid the better. Hence, we regret any tendency to scamp the preliminary work of building an education and character. An engineer needs them both to be fully equipped for his part in the world's work. We in America have come in these latter days to the parting of the ways in technical education. We have swept rapidly along, making tremendous material progress, and gaining a swift adaptability in grasping the ideas which had been accumulated by many hands in unpractical and unapplied research. Now, the choice lies between lending a hand in this very research and scurrying about in the hope of getting some one to do the work for us.

Scientific education had in earlier years a hard battle for existence. It was crowded into corners and shoved into alleyways by the mental luggage of centuries past. To grow, indeed to live at all, it had to take the aggressive, to play the iconoclast, and to push aside the dust-covered impedimenta that were in the way. All this was well, but with the rapid accession of material results has come a certain contempt for the eternal house of learning in which it must forever dwell. The result has been that American technical education has laid too much stress upon the acquisition of bare facts, a knowledge as dead and unfruitful of intellectual growth as a defunct language. For these facts, however important in themselves, are the fruits of others' sowing, and the acquisition of them merely the diligence of the unthinking gleaner. So long as the pickings are good, the gleaner flourishes, and in course of his hum-drum task he may sometimes gain the skill of the husbandman; but it is in spite of his labor not because of it. Permanent supremacy comes only with a deeper kind of culture, and toward that the efforts of the coming generation must be directed. We are moved to this defense of the foundations of specialized knowledge by the recent announcement that three distinguished professors in Columbia University have offered their resignations in protest against the brushing aside of the culture courses which they represent. We do not know either the [illegible] affected or the full merits of the issue which [illegible] this we do know, that when general culture [illegible] rgraduate instruction, post-graduate instruction [illegible] the loser. In this world of hard work a man to [illegible] success must be able to do some one thing better than [illegible] know one thing more thoroughly; [illegible] to make [illegible] worth the knowing and the doing and to give that success [illegible] he must have learned the relation of both to [illegible]

Entrance of Allis-Chalmers Into Electrical Field.

One of the most important and far-reaching events of recent years in the field of industrial electricity is the entrance into it of the Allis-Chalmers Company. With regard to this action on the part of this well-known concern, respecting which rumors have been in circulation so long, no further doubt appears to exist, and thus one of the most formidable oppositions which the existing great manufacturers have had to encounter takes shape and organized form. The creation of this new competition would appear to have been inevitable from the standpoint of the Allis-Chalmers people, and the present movement may be said to date back to the entrance of the General Electric Company into the steam turbine field, and to the action of that important concern in selling its dynamos and steam turbine units as a complete generating plant to the entire exclusion of the reciprocating engine with which the fame and reputation of the Allis-Chalmers Company have been so closely associated in the past. It is understood that the Allis-Chalmers Company expressed to the General Electric Company their willingness to undertake in its behalf the manufacture of the steam turbine in large shops already well equipped for such work, leaving to the General Electric Company the manufacture of the electrical part of the combination; but these proposals, if made, were evidently not accepted. Finding themselves thus cut off by the General Electric and Westinghouse production of steam turbines as well as generators, from a very large portion of the work which had constituted no slight share of its business, the Allis-Chalmers Company have determined to redress the balance of things by entering the electrical field for the production of heavy machinery, believing that with unsurpassed mechanical experience, with all the heavy apparatus free from patent litigation, and with the command of some of the best electrical engineering talent in the country, and with energy and good judgment, it might well make itself in a short time a very formidable factor.

We understand, therefore, that the Allis-Chalmers Company are to take up immediately the manufacture of heavy electrical generators for the largest class of work and are at once entering that field. In addition to this, and supplementing their well-known reciprocating engines, they are, after two years of very careful research, also prepared to supply a steam turbine which is in efficiency equal to the very best known in Europe. They have also, as noted recently in these columns, taken up the manufacture of one of the largest and best-known types of gas engine—the Nürnberg—and have now secured from the famous Swiss firm of Escher, Wyss & Company, who designed the Niagara turbines, the exclusive rights for the manufacture of their hydraulic turbine, of whose experience and plans they will derive the full benefit.

One of the first steps in connection with the new departure has been the creation of an electrical department, in regard to which work is now going forward. At the head of the engineering staff will be Mr. John F. Kelly, so long and so favorably known in connection with the Stanley interests. He will be the active engineer in the company so far as electrical matters are concerned, as its electrical director, but associated with him in an advisory and consulting capacity will be Mr. William Stanley, Jr. It will be readily recognized that in these two gentlemen the company has acquired the services of some of the very best talent now available.

A great many details with regard to this momentous action are not yet ready for publication, but we understand that Mr. Kelly has been busy both at the company's works at Scranton and at their Western shops in making plans which will give immediate effect to the campaign of development along electrical lines, which the executive officers of the company have carefully laid down. We expect in a short time to be able to give some further details in regard to this matter.

Warships and Wireless Telegraphy.

A Washington dispatch states that a series of tests of four systems of wireless telegraphy will soon be made by warships in the vicinity of New York. The progress of wireless telegraphy in the navy recently is considered to have been very satisfactory. In one case the flagship *Kearsarge* and the *Minneapolis* communicated with each other by the wireless method at a distance of sixty miles.

The Pupin System Validated in Germany.

Dr. Michael I. Pupin, who recently went abroad to attend the final argument on the opposition to the granting of a German patent upon his loaded conductor, reports by cable a sweeping victory. The case has attracted wide attention. The patent will issue to the Siemens & Halske Company. The opposition was entered by several rival manufacturers of cables and by the postal administration of Germany, which claimed to have anticipated the invention with certain experiments with loaded conductors.

It is interesting to note the thoroughness with which the invention has been investigated by the German Patent Office. The experimental tests which formed a part of this investigation are reported very fully in Electrical World and Engineer, December 27, 1902. They demonstrate the correctness of Prof. Pupin's theoretical deductions as to improvement in transmission resulting from introduction of the coils or loads into the conductor, and the essential conditions of distribution of the coils with respect to the wave length. The prior art was exhaustively collected and considered by the German examiners. The granting of the patent is, among other things, their answer to Heaviside's claim, put forth in the "Encyclopædia Britannica," that he and not Prof. Pupin made this invention. In his article on "Telegraphy" Heaviside says ("Encyclopædia Britannica," Vol. XXIII, p. 218):

"Telephone wires in air, for long-distance telephony, should have L as large as possible. . . . The difference between $L = 2$ and $L = 20$ or 30, which is produced by separating the wires, is enormous, and largely multiplies the distance over which telephonic waves can be carried.

"But it is the improvement of signaling through cables that is most important, if it can be done. . . . The writer invented a way of carrying out the principle other than uniformly, and recommended it for trial; viz.: by the insertion of inductance coils in the main circuit at regular intervals, say one per mile, according to circumstances. The time constants of these coils should be as large as possible, so that the average inductance may be largely increased without a large increase in the average resistance per mile. The action of the coils is similar to that of small detached loads placed upon a string to give it inertia, and enable it to carry waves further. If we wish to imitate a curve containing bends of various sizes by means of dots, it is obviously necessary to have several dots in every bend. So in the substitution of detached inductances for uniform inductance, we need to have several coils in every bend of the electrical wave. It is easy to say that so many coils will be wanted in such a length, in telephony, for example, if we can fix upon the shortest wave length, by using the known formula for wave length. One could do that without being considered to make a new discovery. But this does not answer the question how few the coils may be for telephony through a cable. Theoretically, we want an infinite number, i. e., uniform inductances. We must sacrifice something. The shortest telephonic wave length necessary to be considered is a doubtful element, and there are unmentioned interferences to be allowed for. Hence, experiment alone can decide how few the coils need be for telephony through a distance far exceeding that possible without the coils. Nothing particular has been done in Great Britain to carry out the writer's invention, but in America some progress has been made by Dr. Pupin, who has described an experiment supporting its practicability; the length telephoned through was increased five times by inserting the coils."

Heaviside's suggestions, upon which he places so much reliance, are interesting. But on the whole they are surpassed in importance, as they were preceded in time, by the researches of the late A. Vaschy,[1] an engineer of great eminence, connected with the telegraphic and telephonic service of the French Government.

Both Vaschy[2] and Heaviside[3] illustrated the beneficial effect of high inductance by the analogy of the mass of vibrating strings. Neither seems, however, to have noted the bearing of the Lagrangean problem of the loaded string upon the problem of the loaded conductor, Heaviside's suggestion to the contrary in the "Encyclopædia Britannica" notwithstanding. Prof. Pupin was the first to point out this analogy, and he first extended Lagrange's famous solution to cover a case involving forced oscillations or dissipative resistances.

In disposing of his foreign rights to the Siemens & Halske Company, Dr. Pupin considers that he has placed them where no exploitation would be attempted excepting strictly in accordance with the highest commercial standards. The company deserves congratulation, as well as Prof. Pupin, as the great and recognized ability of its engineers have contributed largely to the final outcome of this long contest.

High-Pressure Power on the Housatonic.

ONOTA and Pontoosuc Lakes, in Pittsfield, Mass., are the head waters of the Housatonic River, which, after crossing the State of Connecticut, flows into Long Island Sound a few miles east of Bridgeport. In its course of 123 miles the river drops 983 ft., between the lakes and tidewater, and affords numerous opportunities for the development of water power.

Over much of its course the Housatonic has carved out for itself a narrow valley whose rocky sides rise abruptly from almost the water's edge and tower hundreds of feet above its surface. Such a combination of natural features affords excellent opportunity for the development of water power under high pressures. Years ago Nicholas Staub, of New Milford, Conn., a town in that part of the Housatonic valley just considered, saw that a great water power might be developed there, and secured a charter from the State Legislature that granted important rights for this purpose, in 1893. After years of negotiation this charter passed into other hands, capital was interested, and in the spring of 1902 work on the great power development at Bull's Bridge, that is now to be described, was begun by the New Milford Power Company.

Bull's Bridge is the site of a highway crossing over the Housatonic River in the town of Kent, and is in that part of the valley where the river has a continuous rapid descent with steep, rocky hills close on either side. To reach the bridge a drive of several miles from the railway depot in Kent is necessary. Near the bridge the valley narrows and the river has cut its way down into solid rock. Below the bridge the river makes a turn of nearly 90°, and then, after flowing nearly straight for about a mile, takes another turn that brings its general direction back to within a small angle of its former course. At a short distance above the bridge a dam has been built across the river, and a canal starting from one end of this dam skirts the hillside for a distance of about two miles, and then terminates in a forebay, where the water stands about 110 ft. above the surface of the river below at the second bend above mentioned. From this forebay a steel pipe carries the water down the steep hillside to the power station on the river bank. This type of water power development, comprising a rather long canal, a moderate volume of water and a gradual fall in a river concentrated at a single point, so as to give a head of one to several hundred feet, is quite common in California, but has seldom been attempted in New England. There is reason to think, however, that water power plants of this sort will yet come to be of importance in the east.

At the point selected for the main dam on the Housatonic the bed of the river narrows down to a width of approximately 80 ft. between high ledges of solid rock, though the width just back of the dam is fully twice this distance. In this admirable situation a solid concrete dam has been laid between the ledges that form the banks of the river and sunk into the natural rock of its bed. This dam is curved in form with a radius of 88.5 ft. at the toe, 104.6 ft. at the crest and 110 ft. at the back or upstream side, the common center of the arcs being near the middle of the river down stream.

At its base the width of the dam is 34.5 ft., and 8 ft. of this width in the part directly below the crest is recessed to a depth of 2 ft. into the solid ledge of the river bed. The toe of the dam is sunk about 3 ft. below the surface of this same ledge. In height from the lowest part of its bed to its crest the dam measures 24 ft., and at the level of the top back edge, which is 1.5 ft. below the crest, the thickness of the dam is 9.5 ft. From bank to bank at its back face the arc of the dam is about 97°, and the toe of the dam is about 80 ft. long. This dam raises the river level and causes it to overflow its banks for a distance of nearly four miles up stream. This raise in the river throws its water into the bed of a small stream called Spooner's Run-Around, as this bed comes close to that of the Housatonic River at a point several hundred feet above the main dam. A few hundred feet below the main dam the bed of the run-around again joins the river. To prevent the escape of water by way of this run-around, save when the river is nearly up to the top of the main dam, a weir dam has been thrown across the lower end of the run-around. This auxiliary dam is 150 ft. long at its crest, which is a straight line, is 10 ft. wide at the crest level, and 25.5 ft. wide at its base.

In elevation the crest of the dam at the head of the run-around is two feet less than that of the main dam across the Housatonic River, so that ordinarily water will flow over the smaller dam before the river reaches the top of the main dam. Flashboards are provided, however, for the smaller dam, which raise its crest line to the same level as that of the larger dam, when desired.

Fig. 1.—Water in the Deep Cut of the Canal.

The main dam is built of large stones and cement concrete, the stones being so placed that there are at least six inches of concrete between them. On both the face and back of this dam the layer of concrete is from one to two feet thick outside of the large stones that go to make up its core. For a distance of about six feet below its crest the main dam is entirely of concrete and the same is true for about seven feet of its width at the toe. From this it will be seen that this dam is a continuous mass of masonry throughout.

Another type of construction has been followed in the smaller dam at the head of the run-around, which has a vertical layer of concrete two feet thick on its up stream face, next to this a rubble wall three feet thick, and then a rock-filled interior, the whole being covered with a layer of cement concrete. This layer of concrete is about one foot thick over the top and down stream face of the small dam and extends some five feet beyond the rock filling at the toe. To provide for the escape of any water that may find its way into the rock filling of this dam, where no mortar or concrete was used between the stones, one or more iron pipes have been set into the concrete covering of the dam near its toe. A short distance below the main dam there is a natural fall over a ledge of rock in the bed of the Housatonic River, and near the foot of this fall the elevation of the water surface is about 44 ft. below the crest of the main dam. The remainder of the fall between the surface of the water in the forebay and the tail water at the power station is obtained through the gradual drop of the river bed. It is estimated that the operation of the power station at full load during a period of twelve hours will lower the pond created by the main dam only one foot in water level.

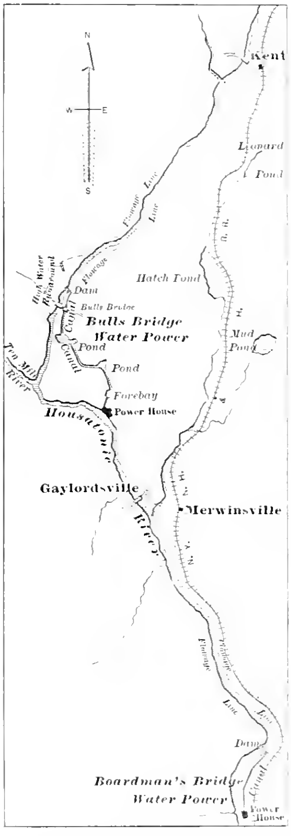

FIG. 2.—MAP OF BULL'S BRIDGE AND BOARDMAN'S BRIDGE WATER POWERS.

Before work could be commenced on the main dam the section of the canal nearest to it was blasted out of the solid ledge, and a cofferdam was built across the Housatonic at a point a little above the site of the dam so as to force the entire flow of the river into the canal. After flowing about 600 ft. in this rock section of the canal the river returned to its natural bed through waste gates. The cofferdam employed to divert the river into this canal was of a construction rather novel in the East, though it has long done effective work in the West, especially along the Mississippi River, where it has been necessary to resist the eroding tendency of the Father of Waters. In this construction the cofferdam is made up of small saplings or brush made into fascines, as they are called, placed with tops up stream, and in alternate layers with heavy stones. Over the completed mass of brush and stone an outside layer of earth is placed. The cofferdam built in this way near Bull's Bridge resisted several floods on the Housatonic when the water went over the top of the dam for days together. The only apparent effect of this flow of water was to wash a few inches of earth from the top of the brush and stone. The rock section of the canal just mentioned begins about 30 ft. from the east end of the main dam, and is separated from it by a high ledge, as may be seen from one of the photographs. This first rock section of the canal is about 600 ft. long from the river to the point where the entrance gates and waste gates are located. At its river end the stone floor of the canal is 17 ft. below the crest of the main dam, and 15 ft. below the crest of the weir dam at the head of the run-around, so that water will flow through this part of the canal with a depth of 15 ft. In cross section this portion of the canal is 25 ft. wide and has a depth of not less than 17 ft. with vertical sides, though the depth is much greater than this in some parts of the cut. The cross section of water flowing through this rock cut will be 375 sq. ft. when the flowage line is up to the top of the small dam at the run-around.

At about 600 ft. from its river end the canal widens out into an entrance chamber, and here the flush, waste and entrance gates are located. The waste gates, of which there are two, are located at the down-stream end of a spillway on the side of the canal next to the river. This spillway is about 150 ft. long and its elevation is the same as that of the crest of the main dam. Each of the two waste gates is built up with 9-in. square hard pine timbers bolted together, and closes an arched opening 10 ft. wide and 8 ft. high in a concrete pier that carries vertical guides of heavy timber. Each gate is divided into two equal parts horizontally, so that one-half can be raised without raising the other. At each of these waste gates the elevation of the arch floor is about 2.3 ft. less than that of the canal floor. The concrete pier that carries these two waste gates has its top 28 ft. above the floor of the arched openings in its base, and 10 ft. above the crest of the main dam. Next to the waste gates comes the flush gate, which is 16 ft. wide, and has its top edge at the same elevation when in normal position as the top of the main dam. The floor of the opening closed by this gate is 2.5 ft. below the crest of the main dam, so that by lowering this gate an opening from nothing up to $16 \times 2.5 = 40$ sq. ft. may be provided for water that is just up to the crest of this dam.

The Housatonic River is subject to severe freshets, owing to the rapid descent of its bed and the precipitous nature of the territory through which it flows. To provide for these freshets the large capacity of spillways, flush gates and waste gates has been made. When the river is only moderately full its entire flow is intended to pass into the rock cut of the canal which has an area in cross section of 375 sq. ft. up to the normal flowage line, which is on a level with the top of the smaller dam, but is two feet below the top of the main dam. When the river has risen to just the crest of the main dam, the cross section of water discharged over the smaller dam will be $2 \times 150 = 300$ sq. ft. Opening the flush gate adds $2.5 \times 16 = 40$ sq. ft. to this discharge area, and full opening of both the waste gates gives $8 \times 10 \times 2 = 160$ sq. ft. more. The total of these discharge sections amounts to 500 sq. ft., to which must be added $24.4 \times 2 = 48.8$ sq. ft. to account for the rise of 2 ft. in the flowage line of the canal. It thus appears that the total cross section of discharge in time of freshet may be $548.8 + 375.0 = 923.8$ sq. ft., or nearly 2.6 times the normal canal area of discharge, before any water goes over the main dam. As the freshet water rises above the crest of the main dam, the length of the discharge line, over and above the openings at the discharge gates, becomes 150 ft. for the smaller dam, plus about 200 ft. over the main dam, plus the 200 ft. of spillway at the side of the canal next to the waste, plus the 16 ft. at the flush gate, a total of 566 ft.

FIG. 3.—ENTRANCE GATES IN FRONT, FLUSH AND WASTE GATES AT RIGHT.

The canal entrance gates set squarely across the entrance chamber next to but at nearly a right angle with the plane of the flush and waste gates. Four entrance gates, each of heavy timber, moving in wooden guides, are provided, and like the former gates are provided with hand-operated raising and lowering gear.

Certain portions of the canal below the entrance gates are provided with spillways on the side toward the river, so that their total length along the canal amounts to about 1,000 ft. In some parts of its course of about two miles the canal is built entirely in earth, and in such cases the area of cross section up to the normal flowage line is 450 sq. ft. The normal depth of water in this cross section is 14.6 ft., the width of the bottom of the canal is 8.9 ft., and the side slopes are 1½ to 1. These slopes are paved with heavy stones to a depth of 2 ft., and this paving runs up to an elevation 2 ft. above the crest of the main dam. As the canal for much of its

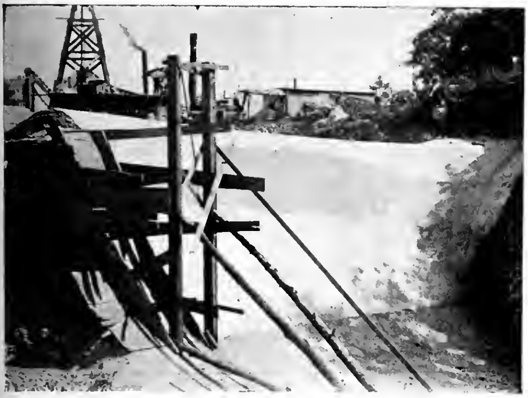

FIG. 4.—SECTION OF DAM, BULL'S BRIDGE.

length runs on a side hill, a cut on one of its sides and a fill on the other was necessary in some of its sections, and the same section is often partly in rock and partly in earth. At two points in its course the canal encounters comparatively low ground, and in these places it widens out into ponds with dikes to prevent the return of its water to the river. These ponds add somewhat to the storage capacity above the main dam.

At the forebay on the hill above the power station the canal

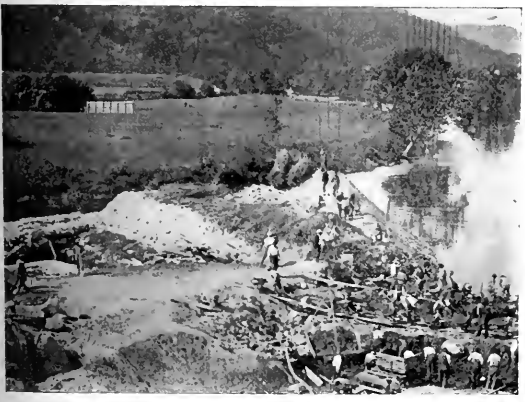

FIG. 5.—BRUSH AND STONE COFFERDAM, BULL'S BRIDGE.

widens into an entrance chamber that is 60 ft. broad at the racks. These racks are about 20 ft. high and have a slope that amounts to 4 ft. in horizontal projection. About 21.5 ft. in front of these racks and separated from them by a heavy framework are the gates that close the ends of the steel pipes which run down to the power house. Each gate is built of hard pine timbers and is in two horizontal sections that can be moved independently. Concrete forms the floor of the entrance chamber, and the head and wing walls of concrete on three sides of this chamber are 7.5 ft. across on top at their thickest points. Where the base of the head wall joins its concrete foundation its thickness is about 18 ft. The top of these walls is two feet higher than the crest of the main dam. Hand-operated gearing for moving the gates is located on top of the head wall. In this wall provision has been made for two steel pipes to convey water down to the power house, one of these to be of 8 ft. and the other pipe of 13 ft. diameter.

The 13-ft. pipe is already in position, and the 8-ft. pipe will not be erected until some future time. This 13-ft. pipe, after reaching the power house, runs along outside of its river front, and connects with seven smaller pipes that pass through the wall and to the water wheels inside. At the end of this horizontal section of the main pipe, which shrinks in diameter as pipes for the wheels are taken off, it turns into a vertical position and extends to an elevation equal to that of the crest of the main dam. The standpipe thus formed acts to relieve any undue pressure such as might be caused by the hydraulic ram action following the shutting of some of the wheels too quickly.

Inside the power house are six main generators and two exciters, each direct-connected to its own set of horizontal wheels. Energy from the six alternators will be raised to a pressure of about 30,000 volts, and then transmitted to Waterbury, New Britain and other cities of Connecticut, there to be used by electric lighting and railway systems.

All the above hydraulic work has been designed and constructed under Mr. W. S. Morton, chief engineer of the New Milford Power Company. The president of this company is Mr. Robert N. King, who has previously developed large water powers for electrical transmission on the Apple River, in Wisconsin, and on the Hudson River, at Mechanicville, N. Y. Mr. King and Mr. Morton have been associated in some of this earlier electrical work.

Melting Out Frozen Water Pipes Electrically.

During the recent intense weather the method of thawing out frozen water pipes electrically was undertaken successfully at Altoona, Pa. Mr. E. B. Greene, the well-known superintendent of the Edison Electric Illuminating Company of that city, who has been conducting this still novel and interesting work, writes us as follows concerning practical results:

We use for this purpose alternating current of low voltage, the maximum voltage not being over 50. The method of doing this, as you know, originated with Messrs. Jackson & Wood about the year 1900, so you will appreciate that it is not new with us. We use a 25-kw transformer wound for 50 volts, using an amperemeter to know what quantity of current we are using, and reduce the voltage with a water rheostat, using common table salt to impart the necessary conductivity.

The transformer, water rheostat and instruments are assembled in a box which is hauled out to the place desired to use, when the transformer is connected up to run as in ordinary methods of lighting, using the water rheostat on the primary side of the transformer (as this requires a very much smaller vessel for the water rheostat). The secondary, or low-voltage cables, are connected directly to the spigot or to the pipe inside the building, the other one being connected to a fire plug, or, if more convenient, to the pipe in an adjoining house, which then completes the circuit on the iron pipe for the low potential.

We have thawed 250 ft. of one-inch iron pipe in twenty minutes actual time of current on, using between 18 and 20 kw. In smaller services, say ¾-in., and on 30 or 40 ft., we have thawed out in from five to eight minutes, using about 11 to 15 kw. The apparatus is very small and it is quite a convenience to people to have water, when their pipes are frozen, in two or three hours after asking to have the apparatus connected up. There is, of course, very little business in the sale of current in connection with the above, but the advertisement we get from being able to help out people who don't have water we think will repay us amply for the trouble and the expense entailed.

As you, no doubt, can see from the above the cost of sending out the transformer, the time of the men connecting up and disconnecting, and the draying charges would leave very small margin unless you would charge an excessive price, which we don't believe it pays us to do. The cost varies very much. The cheapest job, which was near by the station, was $2.50; the most expensive one was $9.50; yet the amount of current used is a very small amount as compared with the charges for labor and drayage.

The Frequency Changers at Montreal.

By B. A. Behrend.

THE City of Montreal, Quebec, obtains electric energy for power and lighting from three plants, which have three different frequencies. The Chambly power plant supplies alternating current at 66 cycles, the Lachine Hydraulic Land & Power Company generates alternating current at 60 cycles, and the Shawinigan Water & Power Company generates alternating current at 30 cycles. Since the consolidation of these three plants a compromise frequency of 63 cycles has been adopted.

At Shawinigan Falls there are installed two 3,750-kw generators operating at 180 revolutions and 30 cycles and generating 2,300 volts of two-phase current. By means of transformers the two-phase current is changed to three-phase current of 55,000 volts, which is transmitted from Shawinigan to Maisonneuve, a distance of 85 miles. In the sub-station at Maisonneuve, a suburb of Montreal, the 30-cycle, three-phase current is stepped down from 44,000 volts to 2,300 volts. The long-distance line between Shawinigan Falls and Maisonneuve is the longest line east of the Rocky Mountains, and it is operated at the high potential of 55,000 volts at the generating end and 44,000 volts at the receiving end. The line is made of aluminum cable consisting of seven strands No. 6 B. & S. gauge. The wires are mounted on porcelain insulators, the distance between wires being 60 inches. The porcelain insulators are supported by locust pins. The wires are arranged in equilateral triangle. Fig. 1 is a picture of the sub-station in which are installed five 1,066-kw frequency changers designed and built by the Bullock Electric Manufacturing Company, of Cincinnati. The incoming line is clearly shown in the background of the picture. The three-phase, high-potential current is reduced by three Westinghouse transformers from 44,000 volts to 2,300 volts. The five groups of frequency changers which are clearly shown in Fig. 2, change the current from 2,300 volts three-phase 30 cycles to 2,300 volts three-phase 60 cycles. As the picture shows, the frequency changers are set in a row with their shafts parallel. The machine on the left is the 30-cycle motor; the machine to the right is the 60-cycle generator; the exciter which is shown on the right-hand side of the set serves as starting motor and also excites the two alternators. The rating of each set is 1,068 kw at 2,300 volts 60 cycles, 100 per cent. power factor, or 800 kw at 75 per cent. power factor. The speed of the frequency changers is 450 revolutions, the motor being

FIG. 2.—FIVE FREQUENCY CHANGERS AT MONTREAL.

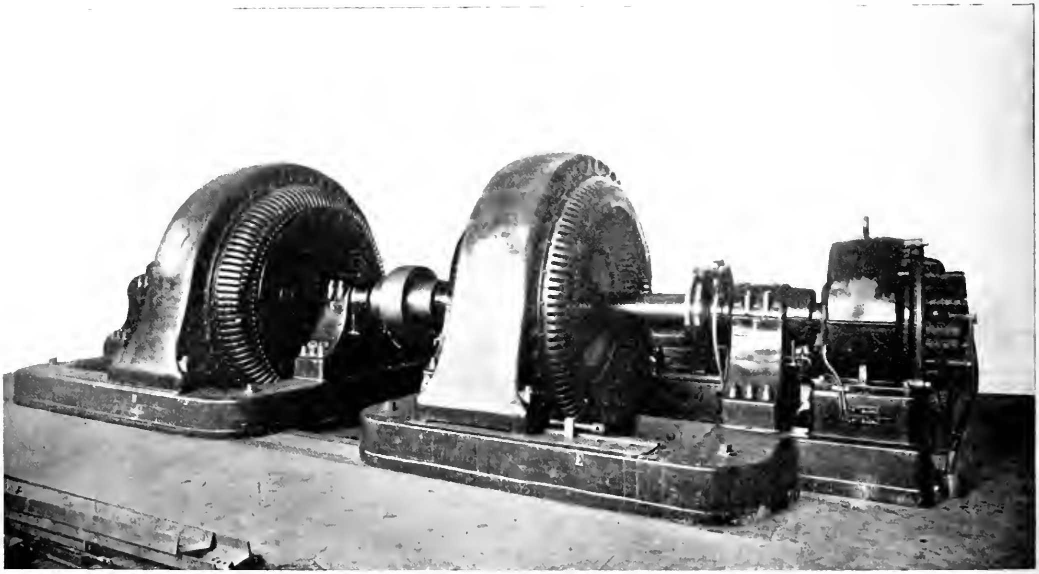

FIG. 3.—ONE OF THE 1065-KW. FREQUENCY-CHANGER UNITS.

an 8-pole machine, the generator a 16-pole machine. Fig. 3 shows one of the sets. The stationary armatures can be moved parallel to the shaft so as to expose the armature and fields for inspection

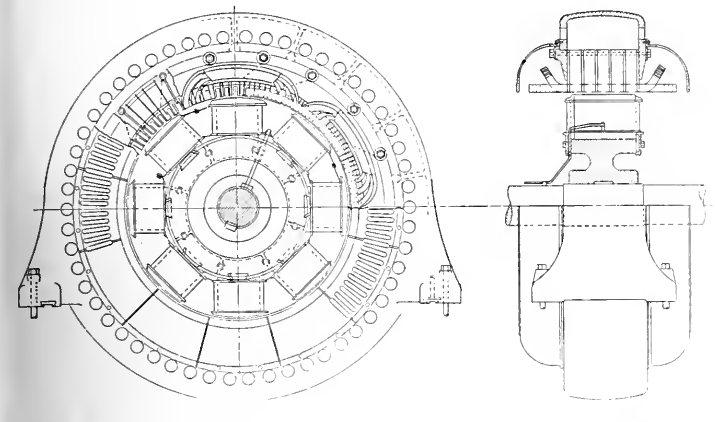

FIG. 5.—1100-KW., 2,300-VOLT, THREE-PHASE, 30-CYCLE SYNCHRONOUS MOTOR.

and repairs. The machines are mounted on I-beams, as shown in Fig. 4, which is an outline drawing of the general arrangement of the machines. Some of the constructional features of the motors and generators are shown in the assembly drawings, Figs. 5 and 6.

it was deemed advisable to use large exciters in order to facilitate the starting of these sets, as at the moment of starting the current taken is quite considerable. A 30-cycle induction motor direct-connected to a 80-kw direct-current generator is used for the starting of the frequency changers.

The operation in multiple of frequency changers is of considerable interest. Imagine a frequency changer to be in operation and a second frequency changed is to be connected in parallel with the first. Imagine that the first set is carrying full load and that the second set is to divide the load with it. The motor can be synchronized in the usual manner by adjusting the field current so that the potential difference between the bus-bars and the synchronous motor vanishes. If the generator is synchronized in the same way it is not possible to put a load on the machine. If the field current of the generator is diminished or increased the load of the frequency changer remains unaltered and the effect of changing the excitation results only in an increase of the cross currents between the two sets. Now then, in order to make the second frequency changer divide the load with the first, it becomes essential to abandon the usual way of paralleling. The following reasoning will at once give us a solution of the problem. Let us assume that both sets are in operation and are dividing the load equally. The saturation curves of the machines being the same, it is

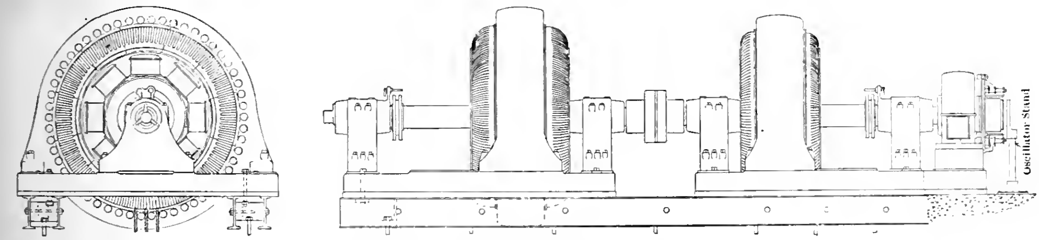

FIG. 4.—OUTLINE OF 1065-KW. FREQUENCY CHANGERS.

On account of the high peripheral speed of 8,000 ft. per minute of the revolving fields, the mechanical construction of the rotating parts has to be made solid and reliable. The rotor spiders are made of cast steel with dove-tailed slots milled into them. The pole pieces are held by means of wedges in these slots. The spider is designed with a central web, which is the best construction for high-speed rotating wheels. These machines were tested at the shops of the Bullock Company at a surface speed of 12,000 ft. per minute.

The high combined efficiency of the sets is shown in the curves represented in Figs. 7 and 8. Fig. 7 shows the combined efficiency for 100 per cent. power factor on both machines for an output of 800 kw at the generator end, while Fig. 8 shows the combined efficiency for an output of 1,066 kw, 100 per cent. power factor on both machines. The combined efficiency includes all the losses of the motor and generator and the bearing friction and windage of the set. At an output of 800 kw at 100 per cent. power factor the combined efficiency of the set is 89.2 per cent., and at an output of 1,065 kw at 100 per cent. power factor the combined efficiency of each set reaches the extraordinarily favorable value of 91 per cent.

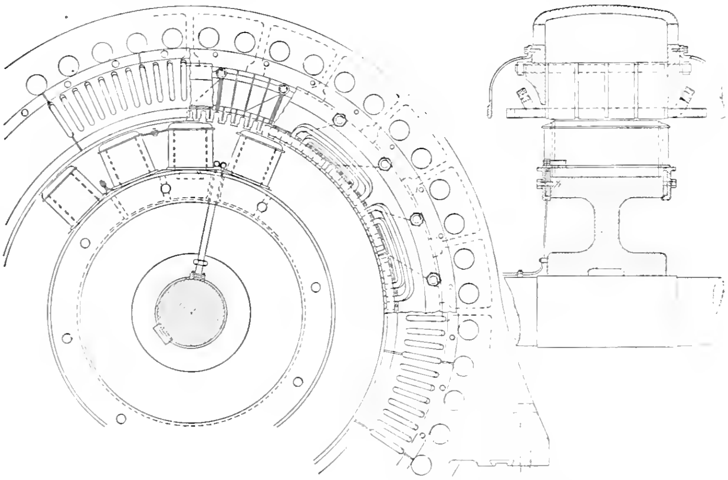

FIG. 6.—1065-KW., 2,300-VOLT, THREE-PHASE, 60-CYCLE GENERATOR.

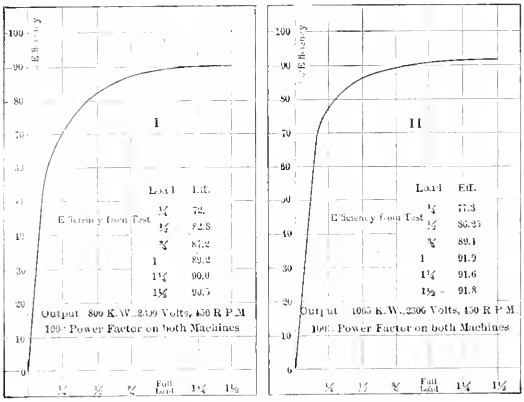
The frequency changers are started from the exciters. The exciters are good for 75 kw at 120 volts. Although the excitation of each machine does not exceed 18 kw under any conditions of load,

clear that the exciting currents of the machines must also be the same if the load be distributed uniformly between them. As juggling the field currents after the machine has been thrown in parallel has no other effect than to increase the cross currents, it is at once evident that the field currents have to be adjusted properly before the machines are thrown in parallel. Hence, assume the first set in operation with

125 amp. excitation on the fields of the generator. If we wish to throw the second set in parallel with the first set, we first synchronize the motor of the second set and then make the excitation of the generator of the second set 125 amp. The bus-bar voltage on which the first set is operating is 2,300 volts; the second set has the same excitation and the terminal voltage of its generator is, therefore, greater than the bus-bar voltage on which the machine is to operate. Assume the drop of the machine at this load to be 12 per cent., then the generator of the second set at 125 amp. excitation on its fields will generate 2,580 volts. The switches must be closed between the two machines at these unequal voltages and the two sets will pull each other in parallel with the load distributed equally between them.

The aggregate power of the frequency changers in this sub-



FIGS. 7 AND 8.—CURVES OF COMBINED EFFICIENCY.

station amounts to 11,000 kw, of which, of course, only one-half is utilized on account of the changing from 30 cycles to 60 cycles. The plant has been in operation since February, 1903.

The unique character of this plant operating on a system which Mr. Alton D. Adams has recently called in these columns, "the greatest center of transmitted power," will justify my supplementing Mr. Adams' article. (*) The line between Shawinigan Falls and Montreal was designed by Mr. Ralph D. Mershon, and the substation by Mr. Wallace C. Johnson, chief engineer of the Shawinigan Water & Power plant.

Doherty Medal Competition.

Mr. Ernest H. Davis, secretary of the National Electric Light Association, has issued the following important notice:

I beg to call your attention to the following extract from Mr. Henry L. Doherty's presidential address at the Cincinnati convention: "We must give underground construction more consideration than heretofore. We had hoped at this meeting to have a text paper on this subject, but were unable to obtain assistance. What we want is a paper so complete and detailed that it will enable any central station man who is forced to put his wires underground to undertake the work simply by the guidance of this paper; and, with the consent of your executive committee, I recommend that we make this a feature of our next convention, and with your further consent I will award a gold medal, properly inscribed, to the contributor offering us the most complete and comprehensive paper on underground construction, for either alternating or direct-current plants, or a combination of both; the selection of the best paper to be made by a suitable committee to be appointed by the incoming president."

Mr. Doherty's generous offer of a gold medal was accepted by the Association, with the condition that not less than five papers be contributed, but for certain reasons it was decided to postpone the competition until this year. The competition is now open to all wishing to contribute a paper on "Underground Construction." Papers must be received at the office of the Association not later than April 21. Three copies of each paper are requested.

Radioactivity and Radiation.

By J. B. Whitehead, Ph.D.

In an article with the above title which appeared in your issue of January 23, Dr. Louis Bell sounds a general warning against the too hasty interpretation of experiment and consequent construction of theory, and in particular he suggests that the new but generally accepted theory of ionization and its bearing on the phenomena of radioactivity, may perhaps require modification in the light of certain other kindred observations of Blondlot and Sanford. The condemnation of the tendency to jump to conclusions, and of the thirst for sensational deductions will receive general concurrence, but the illustration cited seems hardly a case in point.

If there are two pieces of work in the recent literature of experimental physics the results of which are to be doubted, they are that of Blondlot on the N-rays and that described by F. Sanford in the *Physical Review* of December, 1903, on a so-called new type of radiation.

The name of Blondlot is sufficient to attract attention and respect to any of his work, and his claim to have discovered a new type of "ray" was received with widespread interest. Physicists in all countries immediately began experiments, and further investigations by Blondlot were awaited with impatience. As time passed, however, and other experimenters failed in attempts to repeat Blondlot's observations, an element of doubt arose throwing a haze of uncertainty over the whole work. There need only be mentioned among the many questioning the existence of the N-rays, the names of Rubens, Wood and Lummer. In fact, the last-named has shown that many of Blondlot's observations can be explained as being largely due to physiological causes. These observations were frequently on the variation of the intensity of illumination of bits of paper, metal, or of a spark in a dark room. Now, it is common knowledge that if one looks steadily at a star on a dark night, by shifting the eye a little to one side the star appears to change in intensity. Lummer has shown that variations such as those observed by Blondlot may be largely due to such subjective causes, and he points out that a measuring instrument other than the eye must be used before observations of precision can be had. Those of Blondlot's results which are most conclusive and least subject to Lummer's criticism are the ones referring to the condensation of the rays to foci by lenses, thus giving a means of determining their wave length. Apparently, however, all attempts to repeat the original observations have failed, so that until new evidence appears we must reserve judgment here also. Prof. Wood, of Johns Hopkins University, has attempted to repeat many of Blondlot's experiments without success.

From the account in the *Physical Review*, the work of Sanford appears so crude, so wanting in description and data, and so subject to criticism generally that it is difficult to understand how it can be accepted in evidence of anything new. There is hardly an observation which he describes that cannot be explained by the ordinary phenomena of ionization and Röntgen rays, primary or secondary. The observations on reflection and polarization require repetition and fuller description, before they can attract serious attention. The secondary Röntgen radiation which would seem to account for some of Sanford's observations were observed by Perrin in 1897, and their properties have been investigated by Sagnac, Townsend, Thomson and others.

From these facts it seems hardly possible as yet that we have failed to take into sufficient account these new types of radiation in the rapid development of our theories of ionization and radioactivity; theories, the basis of which rest on experiments as conclusive and reliable as they are beautiful.

"Good in Everything."

A special cable dispatch from Paris of January 30 to a New York daily paper says: "A French scientist, with the English sounding cognomen of Griffiths, has discovered evidence of radioactivity in the petals of several odoriferous flowers. When geraniums and sunflowers are placed near selenium with which an electric current has been interrupted the metal at once displays signs of strange activity and becomes an electric conductor. Dr. Blondlot this week explained to the Academy of Medicine of Paris the peculiar properties of these rays.

Application of Graphics to Power House Location.

By SIDNEY DIAMANT.

IN locating the electrical centroid of an area, over which concentrated loads exist the relative position of which is known, the method described by Dr. Bell has been generally employed. The scheme described in this article occurred to the writer in his desire to develop a method which would eliminate the possible confusion resulting from working directly on the area under consideration.

Given the position and the intensity of the loads, either absolute or relative, the problem is to locate the electrical centroid. As shown in the diagram, the position of a number of loads is located and their relative intensities are represented by the numbers 1, 3, 4 and 6, for example. Draw two axces, *O X* and *O Y*, at right angles with each other. (It has been observed by actual trial that the axces may make any angle with each other and that these axces may pass among the loads if it be more convenient for plotting because of limited space). Project these loads on the axces and continue, for a short length, the lines from these projections perpendicular to the axces. It is then desired to locate the position of two lines or neutral axces on which lies the centroid. The simultaneous position of the centroid on these two axces is at their intersection and locates the true centroid of the various loads.

To locate the neutral axis which is perpendicular to *O Y*, draw a line, *a-e*, parallel to the lines of action of the horizontal load components and on this line lay off successively to scale the different load values, *a-b*, *b-c*, *c-d* and *d-e*, following in the same direction. From the center of this line draw *s'-s* perpendicular to *a-e* and make *s'-s* equal to *a-s'* to conveniently limit the extent of the layout. Draw from the point *s* the component forces, *s-a*, *s-b*, *s-c*, *etc.* This merely enables a combination of the forces in such a way as to effect a neutralization of a component of one load by a component of another. The forces are decomposed as follows:

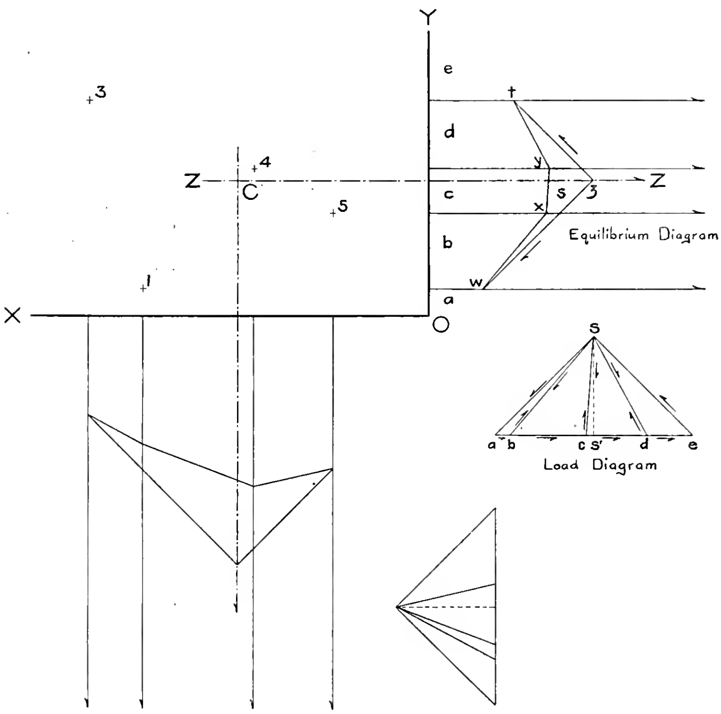
FORCES.	COMPONENTS. Load diagram.	Equilibrium or directional diagram.
(*a-b*)	*b-s* / *s-a*	*w-x* / *z-w*
(*b-c*)	*c-s* / *s-b*	*x-y* / *x-w*
(*c-d*)	*d-s* / *s-c*	*y-t* / *y-x*
(*d-e*)	*e-s* / *s-d*	*z-t* / *t-y*

The letters denote the direction and path of the components; as *a-b* denotes direction from *a* tob and along the path *a-b*. Since the forces *a-b* and *b-c* have a common component, *b-s* and *s-b*, along the same path, but in opposite directions, *b-s* component of *a-b* neutralizes *s-b* component of *b-c*. Likewise, *c-s* component of *b-c* neutralizes *s-c* component of *c-d; d-s* component of *c-d* neutralizes *s-d* component of *d-e*, so that these components are of opposite sign in the equation of forces and components. Therefore, the sum of the loads, *a-b*, *b-c*, *c-d* and *d-e* is held in equilibrium by the sum of the force components, *s-a* and *e-s*, since the equal and opposite components cancel each other. Thus the total load has *s-a* and *e-s* as load components.

Next, as to the construction of equilibrium diagram: In naming the forces the graphic notation usually employed will be made use of so that a line which separates spaces *a* and *b* indicates the direction of a force, *a-b*. From a convenient point, *w*, on the force directional line, *a-b*, which is a continuation of a line connecting the actual position of the load and its projection on the *O Y* axis, draw the indefinite line, *w-x* (the subscript letter is not shown in the sketch, but is the indefinite end of the line on which is the letter itself, without the subscript, ocupying a definite position) parallel to the force component, *b-s*, of the load diagram. The point, *x*, is at the intersection of the indefinite line, $w\text{-}x_i$ with the next force directional line, *b-c*.

Then from *x* draw the indefinite line, $x\text{-}y_i$ parallel to the force component, *c-s*, of the load diagram and the intersection of this line with the next force directional line, *c-d*, determines the point, *y*. From *y* draw the indefinite line, $y\text{-}t_i$ parallel to the force component, *d-s*, of the load diagram. Then the intersection of this line with the next force directional line, *d-e*, gives the point, *t*. From *w* and *t* draw the indefinite lines, $w\text{-}z_i$ and $w\text{-}t_i$ respectively, parallel to the load components, *s-a* and *e-s*. Then *z*, the intersection of these two lines, is the point through which passes the resultant of the force components perpendicular to the *O Y* axis.

Because all the load components perpendicular to the *O Y* axis act in directions parallel to one another, the resultant, *Z-Z*, acts in a line parallel to the lines of action of the load components. Since the centroid is the point through which passes the resultant of all the loads, the centroid of the loads is on a line, *Z-Z*, perpendicular to the *O Y* axis on which the loads are projected. If about this line moments be considered due to the loads acting about their respective lever arms, the algebraic sum of the moments will equal zero. Likewise, a similar demonstration will be true of the projected positions of the loads on the *O X* axis, and the position of a second line, on which is the centroid of all the loads, may be determined. The intersection of these two neutral axes indicates the definite position of the centroid of all the loads in their true positions. If, now, any line be drawn through *C*, the sum of all the products of all the loads on one side of this line multiplied by their respective lever arms equals the sum of the products of all the loads on the other side of the line multiplied by their respective lever arms.



APPLICATION OF GRAPHICS TO POWER HOUSE LOCATION.

The result obtained by this method agrees with that obtained analytically by the following equations:

$$L_x = \frac{A\ 1_{ax} + B\ 1_{bx} + C\ 1_{cx} + D\ 1_{dx}}{A + B + C + D}$$

$$L_y = \frac{A\ 1_{ay} + B\ 1_{by} + C\ 1_{cy} + D\ 1_{dy}}{A + B + C + D}$$

wherein L_x = abscissa of centroid and L_y ordinate of centroid, with respect to the selected pair of axes. A, B, C and D are the respective loads and l_{ax} = distance of load A from Y axis, l_{ay} = distance of load A from X axis.

A power house or a general distributing center located at the centroid will result in the most economic condition of distribution.

British Lamme Single-Phase Railway Motor Patent.

The current issue of the London *Electrician* contains a reprint of the specifications of a British patent granted to B. G. Lamme on "Improvements in Electric Motors," which contains a lengthy discussion of the principles of the railway motor associated with the inventor's name. Owing to the interest of this discussion we reprint in full the specifications, including the drawings.

My invention relates to electric motors, and has for its object to construct an improved series-wound motor for use with single-phase alternating currents. Hitherto alternating currents have been applied to operate series-wound motors, but considerable difficulties have arisen in the form of undue heating, excessive sparking of the brushes and low efficiency, together with want of due regulation. According to my invention, I overcome these defects, not by merely modifying the arrangement of parts of the ordinary series-wound motor, but by providing that certain definite proportions and relations shall subsist between such parts, together with various novel features in the construction of the motor. Since the self-induction of the field magnets and the counter e.m.f. set up by the armature are both dependent on the strength of field, a relation subsists between them which is proportional to the speed of rotation of the armature, the relative ampere-turns and the frequency. A higher speed, a low frequency and few turns on the field magnets compared with those on the armature, will give a lower ratio of the field self-induction to the armature counter e.m.f. Both the field strength and the armature magnetic lines of force increase with the current supplied to the motor, and if saturation is not approached each of these will increase directly as the current, and, therefore, the torque which is produced by them jointly will increase as the square of the current, which would be a highly advantageous condition for electric traction work. Increase in strength of field, however, is accompanied by augmented self-induction which, when working with alternating currents, must be reckoned with. Inasmuch as the resultant of all the e.m.f's is equal to the applied e.m.f., increase in self-induction would result in a fall of speed, and if the self-induction of the motor becomes relatively high, the speed will fall very rapidly, and zero will be reached when the self-induction is equal to the applied e.m.f. Conversely, if the strength of the field is kept constant its self-induction will be constant, and, consequently, the armature speed will not fall unless its own induction be very high.

In the two cases above stated the first is that in which the strength of field is approximately proportional to the strength of the current, and in the second case the field magnetic strength is constant. As previously pointed out, the first case provides favorable conditions for electric traction; but it is limited by the fact that the maximum torque which can be developed may be insufficient for maximum requirements. In the second case the torque is not so limited, but on the other hand the general characteristics of the motor may not be suited to given conditions of working. It is, therefore, advantageous to so proportion the motor as to combine the two cases and thus secure conditions through a certain range of working, in which the field strength is approximately proportional to the current, and have the motor capable of developing the required torque. It has been pointed out that the limitation in the torque developed when the field magnetic strength increases in proportion to the current, is due to the rapidly-increasing self-induction of the field as the current is increased, so that the self-induction soon becomes nearly equal to the applied e.m.f. It is desirable, therefore, to provide means for limiting the self-induction so that it does not normally absorb an undue proportion of the applied e.m.f., and when a heavy torque is required, the self-induction of the field shall not limit the current, but shall permit a sufficient current to flow to produce the required torque. As the cross-induction of the armature through the poles acts with the self-induction of the field in limiting the flow of current, it is desirable that this should also be kept within proper limits. It follows, therefore, that the self-induction of the motor, as a whole, in normal working, should be relatively small with relation to the applied e.m.f., and should also have a limiting value which is less than the applied e.m.f., even when the motor is operating under maximum conditions of torque. The relations between the field self-induction and the armature counter e.m.f. may be expressed as follows: Self-induction of field = alternations × field turns in series × induction per pole × constant. The counter e.m.f. of the armature = revolutions × the number of armature wires × induction per pole × constant. The constants used are dependent upon the characteristics of the supply circuit and upon the units in which the different terms are expressed; their values are determined in any given case, according to well-established laws, and the armature winding is assumed to be of the usual parallel type.

$$\frac{\textit{Field self-induction}}{\textit{Armature c.e.m.f.}} =$$

$$\frac{\textit{Line alternations} \times \textit{field turns in series} \times \textit{induction per pole}}{\textit{Revolutions} \times \textit{amature wires} \times \textit{induction per pole}} \times \textit{const.}$$

since armature wires = 2 × poles × armature-turns in series,

$$\frac{\textit{Field self-induction}}{\textit{Armature c.e.m.f.}} =$$

$$\frac{\textit{Line alternations}}{\textit{Poles} \times \textit{revolutions}} \times \frac{\textit{field ampere-turns}}{\textit{armature ampere-turns}} \times \frac{\textit{constant}}{2}.$$

In a direct-current motor the armature alternations are equal to the product of the revolutions multiplied by the number of poles, and, since this relation may be assumed to obtain in a series alternating-current motor the foregoing formula may be further simplified by substituting the term "armature alternations" for the term "poles × revolutions." It has been pointed out that the self-induction of the motor should be relatively low as compared with the applied e.m.f., since the resultant of the self-induction of the motor and the counter e.m.f. is approximately equal to the applied e.m.f., and it follows that the self-induction should be low in proportion to the counter e.m.f. of the armature in normal working. The relation between the two is expressed in the foregoing formula, and it is now apparent what relations must hold between the elements of the motor itself and between the motor and the external conditions.

In order that the ratio between the field self-induction and the counter e.m.f. of the armature may be low, it is clear that there must be a small number of line alternations, a large number of poles and a high speed, and a small number of field ampere-turns and a relatively large number of armature ampere-turns. The absolute values and the ratios between these several elements which are admissible and suitable for practical design and operation will now be considered. The ratio of field ampere-turns to the armature ampere-turns has, generally, a minimum value which is fixed by the proper operation of the motor itself. If the field ampere-turns are too small as compared with the armature ampere-turns, the magnetic field will be distorted and good commutation will be difficult. The minimum ratio of field ampere-turns to armature ampere-turns is dependent upon many factors in the design, but, in general, it may be said that this ratio should be greater than 0.5 and may sometimes be as high as 0.75.

Therefore, when definite limits have been assigned to two of the ratios in the last equation—namely, the ratio of field self-induction to armature counter e.m.f., and the ratio of field ampere-turns to armature ampere-turns then there is also a definite limit fixed for the remaining term in the equation, i. e., a definite relation between the alternations in the supply circuit, the number of poles of the motor, and its rate of revolution, or, in other words, between the line alternations and the armature alternations. It may be noted that an average working value for the last-mentioned ratio is approximately 0.625, and it has been found that the expression $\frac{\textit{constant}}{2}$ in the foregoing formula closely approximates the reciprocal of 0.625, i. e., 1.6. It follows, therefore, that the last two ratios of the formula cancel out, leaving only the ratios of field self-induction to armature counter e.m.f. and line alternations to armature alternations, for which definite limits are fixed, as hereinbefore pointed out. With a given number of revolutions, the number of poles must be directly proportional to the alternations in the supply circuit. Thus, for instance, if an eight-pole, 700-revolution motor of a certain capacity is required for 2,000 alternations per minute, 3,000 alternations per minute will require a 12-pole motor at 700 r.p.m.

The foregoing considerations indicate the conditions required for securing a relatively low self-induction of the field of the motor. It has been stated that a limiting value of the self-induction of the motor can be secured by suitably proportioning certain parts of the motor. A method of doing this will now be described. The field self-induction and the armature self-induction may both be limited by special construction of the pole pieces. For instance, slots or holes may be cut in the body of each of the field pole pieces from end to end transversely to the direction of rotation, the amount of iron left at the back of the slots being that which is required for the desired induction. The teeth or narrow portions between the slots or holes are of such cross-section that the desired induction through them may be obtained. The slots or holes may be closed, or nearly closed, at the pole faces, and usually this is preferred, as open slots increase the magnetizing power required in the field winding which, in turn, necessitates more field turns, and results in greater field self-induction. The cross-section of iron in the poles is preferably such that but little magnetizing power is absorbed in addition to that required for the air-gap until the current exceeds the normal rated amperes of the motor. Beyond this normal current the teeth between the pole slots rapidly approach saturation. In order to secure this result, the parts in which the cross-section of the magnetic circuit is reduced should be of comparatively short length, but should, of course, be worked at a high induction. It is not necessary or desirable to subject the whole yoke to a high induction, as the desired results can be obtained by having a short length of small cross-section; whereas, if the whole yoke be subjected to a high induction, the losses due to reversals in the core will be objectionably large, and also the magnetic leakage into the surrounding frame and through the field windings will be objectionable.

The self-induction of the armature which results from a cross-induction through the poles, in which the magnetic lines enter at one edge or side of the pole and pass through the core to the opposite edge or side, is also reduced and limited by the arrangement of slots or holes which has been described and which would not be obtained in the same degree if the whole yoke were saturated, provided the field cores in the two cases required the same number of ampere-turns in the field for magnetizing them. The cross-induction of the armature is due to the magnetic flux which passes through the field poles, the path for any given pole being through the teeth at one side, then across the slots and also across the pole back of the slots and then along the teeth at the other side of the pole and back to the armature. The smaller the section of the teeth and the more highly they are saturated, the less will be the cross-induction with a given current in the armature. As it is desired to have the induction in these teeth quite high, it is, as above pointed out, desirable to have the teeth as small as possible, and, therefore, the magnetic reluctance of the field circuit is concentrated near the pole face instead of being distributed through the whole yoke. The total useful flux through the armature and field sets up no effective e.m.f. of self-induction in the armature windings, as it will add to the counter e.m.f. at one part and subtract at another part of such winding. But the e.m.f. set up by the cross-induction does not neutralize itself in the same way, and thus becomes an e.m.f. of the same character as that set up in the field windings. The cross-flux from the armature may be further limited by the suitable interposition of a secondary circuit, if desired. For example, if a slot at the middle of the pole contain a conducting plate or closed coil, it will oppose the magnetic flow which would tend to cross the slot. If the ends of a conductor placed through the middle slot be connected with the outer frame of the machine at each end, or if the conductor be closed around the outside of the yoke, then the secondary circuit thus formed will oppose the flow of the cross-induction which tends to pass through the section of iron back of the slots.

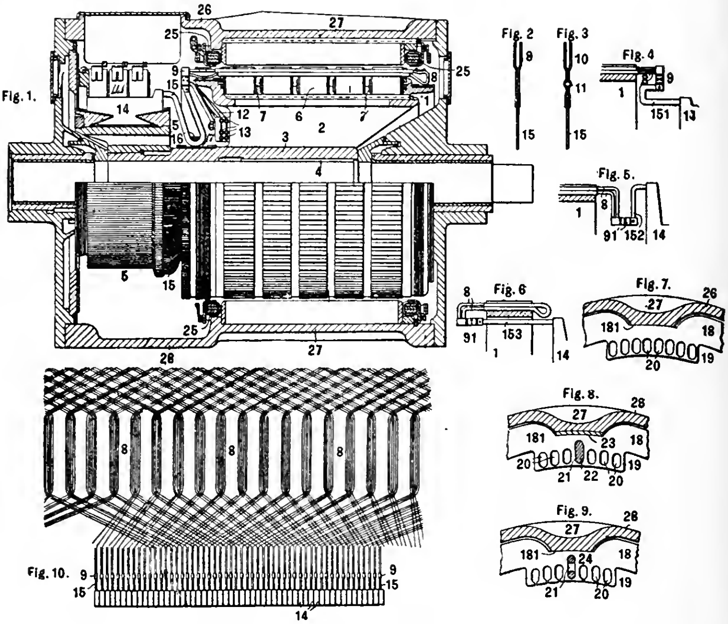
The armature winding of the motor is of the closed coil type and is closed upon itself before being connected to the commutator, relatively high resistance leads being inserted between the winding and the respective commutator bars. As the magnetic field of the motor is alternating, any short-circuited turn through which the magnetic flux from a field pole passes will have a secondary current set up in it. By the well-known laws of the transformer the ampere-turns in such short-circuited secondary will approximate the ampere-turns in the primary winding, which is, in this case, the field magnet winding. Certain coils of the armature winding are short-circuited through the brushes when the adjacent commutator bars to which the ends of the coils are connected are bridged by the brushes, and when the latter are located in neutral positions or without lead, the short-circuited turns surround the paths of the magnetic flux and are, therefore, good secondary circuits in which relatively large secondary currents are set up by induction. This is the principal cause of the excessive sparking in series motors of ordinary construction, when it is attempted to operate them upon an alternating-current circuit. In order to obviate destructive sparking, the current in the short-circuited turns of the armature coil should be limited to an amount materially less than what would normally flow. I have found that by inserting a definite amount of resistance in each of the leads between the closed winding and the commutator bars, it is possible to so limit the secondary current due to the alternating field flux as to prevent injurious sparking. The working currents in the armature winding will not pass through these resistances except at the bars in contact with the brushes, because the armature winding is closed on itself inside or beyond the resistance leads. Consequently, the loss in the winding due to the introduction of the resistance can be relatively small, and when the armature is rotating this loss is distributed successively through all the resistances, thus making the average loss per resistance lead very small. Various ways of introducing such a resistance will be described in connection with the accompanying drawings.

With a given current in the motor, the turn of each armature coil which is short-circuited by a brush will tend to have the same e.m.f. set up in it irrespective of the e.m.f. applied to the motor. Therefore, the resistance in the leads may be such that the short-circuited current developed will be limited in amount, and, generally speaking, with full-load current in the motor; the resistance should be such that the short-circuited current will not exceed, say, twice the value of the full-load current. The resistance in each short-circuit will include the resistance of the turn itself plus the resistance of two of the leads, plus also the resistance of the brush holders and brushes. As will appear from what has already been stated, the conditions for suitably low self-induction and for a proper ratio of field ampere-turns to armature ampere-turns practically determine the number of poles the motor should have with a given rate of alternation and speed. This motor will require a relatively larger number of poles as compared with direct-current motors of corresponding size. Moreover, the conditions of good commutation are that the armature circuits of the motor be connected in parallel, and that the number of turns between consecutive armature bars be small. It follows, therefore, that the voltage of the motor is definitely limited, and it is found that the actual voltage is low relative to that for which direct-current motors may be wound—such, for example, as motors employed in ordinary electric traction. While this characteristic would be a serious limitation in connection with the distribution of energy for direct-current traction motors, it is of minor consequence in connection with alternating-current motors, since transformers may be interposed between the supply circuit and the motors, which may be designed to receive practically any voltage from the line and to deliver any desired voltage to the motors. In service, a motor may require either a constant voltage or a variable voltage. For variable speed work the variable voltage is usually desired. A variable voltage may be obtained by the introduction of resistance or self-induction into the circuit or, preferably, by means of a transformer in which the rate of transformation is suitably changed. The several elements which are involved are the motor, the controller, the supply circuit and the transformer. The motor, as has been pointed out, has inherent limitations as to the voltage for which it can be wound, which are independent of the transformers, the controller and the voltage of the supply circuit. The current and the voltage which can be most advantageously handled by the controller may be entirely different from those of the motor. For example, it may be advantageous to design the controller for one-third of the current and three times the voltage which are required by the motor. The line voltage may, in turn, be entirely too high to be introduced directly into the controller or the motor. It follows, therefore, that the voltage of the motor, the voltage of the controller and the voltage of the supply circuit, and their respective currents, which may be most advantageously utilized, may be widely different. It is possible, however, by means of one or more transformers, to operate a motor adapted to any voltage by a controller adapted to any voltage from a supply circuit of any voltage. A convenient method of control consists in connecting a main transformer across the supply circuit, its secondary being included with the motor circuit but having included in series the secondary of a series transformer, the primary of which derives current either directly or indirectly from the main circuit and is capable of adding to or subtracting from the e.m.f. developed in the secondary of the main transformer.

This invention is applicable in cases where frequent starting is required, as, for instance, in electric traction systems. It is now the common practice in operating electric cars to have two or more electric motors upon each car, and for the purpose of securing varying speeds means are usually employed for connecting the motors either in series or in parallel, and for introducing more or less ohmic resistance into the circuits of the motors. With single-phase motors constructed according to my invention, it is possible to dispense with practically all ohmic resistances for regulating purposes, and it is not necessary to connect the motors successively in series and in parallel for the purposes of regulation, but the motors may be permanently connected either in parallel or in series and all the benefits of the usual series parallel control, as employed with direct-current motors, may be obtained by varying the e.m.f. applied to the alternating-current motors. In some instances it may be desired to connect the motors permanently in series—for instance, in cases where the reduced current will be more suitable for the controllers, or where the increased voltage presents advantages such as would be secured if this voltage were equal to that of the supply circuit. The method of control by means of variable ratio of transformation in the transformer is one which provides a very much higher degree of economy in starting and at lower speeds than is obtained in the usual method of operating direct-current motors where the voltage is reduced by means of rheostats, either with or without the series parallel method of control. In electric traction work, in which starting is frequent, a very large per cent. of the power delivered to the car may be lost in rheostats, thus greatly reducing the efficiency and increasing the cost of operation. It is to be understood, however, that the rheostatic method of control may be used with the form of alternating-current motors herein described, if desired, but usually the advantages of operating by means of transformers with variable e.m.f. ratio without rheostats are very great. The voltage delivered by the transformers is that required by the motor, so that there are practically no losses except those inherent in the transformers and motors, both of which are capable of being so designed as to have high efficiency. With this system full load torque or several times full load torque at starting may be developed with a very small amount of energy from the supply circuit. It also follows that with a given torque developed by the motors, the power taken from the circuit is substantially proportional to the speed of the motors, which is not the case with direct-current motors.

In the accompanying drawings, Fig. 1 is a view, partially in side elevation and partially in longitudinal section, of a motor constructed in acordance with my invention. Figs. 2 and 3 are detail sectional views of two of the combined resistance leads and connectors between the armature conductors and the commutator segments. Figs. 4, 5 and 6 are detail views illustrating modified arrangements of resistance leads for connecting the armature conductors with the commutator segments. Figs. 7, 8 and 9 are detail views of different forms of field magnet core construction. Fig. 10 is a diagrammatic development of a portion of the armature winding and connections between the same and the commutator segments. As here shown, the armature, 1, comprises a skeleton openwork frame or spider, 2, the hub, 3, of which is in the form of a sleeve mounted upon and suitably keyed to a shaft, 4, this sleeve being extended at one end to receive a commutator cylinder, 5, which is also suitably keyed to it. The core, 6, of the armature is built up in the usual manner of thin plates or laminæ, properly spaced apart at intervals by ventilating spaces, 7, and provided with slots which, in the present case, are 72 in number, in which are mounted the insulated conductors, 8, constituting the coils of the armature winding. These coils or conductors, as shown, are of strap copper, the turns of which are located side by side in the slots, forming three separate coils, which span the core from the first to the ninth slot, and so on around the core. The coils are properly joined together at one end of the armature by means of suitable connectors, 9 and 10, so as to form a closed parallel winding. The connectors, 10, are provided with sockets, 11, in which are fastened the outer ends of suitable connecting wires or strips, 12, the inner ends of which are connected to balancing rings, 13, in a well-known manner.

For the purpose of reducing the secondary currents that are generated by the alternating magnetic field in the coils which are short-circuited at the brushes to substantially non-sparking limits, I join the connectors, 9 and 10, to the several commutator bars, 14, by means of relatively high resistance leads, 15, there being in the present case



FIGS. 1—10.—SINGLE-PHASE RAILWAY MOTOR PATENT.

216 commutator bars and the same number of leads. As employed by me, these leads are in the form of strips of German silver, and their dimensions are actually determined, in view of the specific resistance of the material, so as to reduce the secondary current, above referred to, to the desired limits, and the form and arrangement of the leads are also such as to be properly accommodated by the space available and so as to be properly ventilated and securely supported independently of each other. The commutator brushes, 141, are arranged in sets in the holders or arms, and, in the present instance, the arms or holders are eight in number. The brushes and arms may be of usual material and construction and connected in the usual manner to properly co-operate with the commutator cylinder and the supply circuit. As indicated in Fig. 1, the leads, 15, are bent into substantially the form of U-shaped loops, the inner ends of which are held in place by means of a suitable winding, 16, an insulating band, 17, being interposed between the leads and the sleeve, 3, of the armature spider. As illustrated in Fig. 4, the resistance leads, 151, are shown as having a substantially U-shaped form, one arm of which extends beyond the other for connection to the commutator bar and the two arms of which are approximately parallel at the armature axis. In Fig. 5 the resistance leads, 152, are shown as having each a main

body position substantially perpendicular to the armature axis and an outer end which extends approximately at right angles to the body portion for connection to the commutator bar. In this case the end of the armature conductors project inwardly, approximately parallel to the body portions of the leads, for connection to the connectors, 91, which are also substantially at right angles to the body portions of the resistance leads. In Fig. 6 the resistance leads, 153, are connected to the ends of the armature conductors, at the end opposite the commutator, and project through the spider to the commutator and, substantially parallel to the axis of the armature. Other forms and arrangements of resistance leads may, perhaps, be devised which will be adapted for the purpose. These, I have shown, are such as I have been able to devise to most satisfactorily provide the necessary resistance and, at the same time, be economically and safely disposed in the available space in the motor.

As has already been pointed out, the number of field magnet poles of the motor must be directly proportional to the rate of current alternation in the supply circuit, and other conditions, which have been heretofore pointed out in detail, render it desirable, and, in fact, necessary, for successful operation that the rate of line alternations shall be low, and that the rate of armature alternations shall be relatively high. The motor here illustrated and described was designed for a frequency of 2,000 line alternations per minute, and the motor which is adapted to this number of alternations and the other conditions has eight field magnet poles. The field magnet core, 18, is in the form of a hollow cylinder and is built up of thin plates or laminæ, the laminated construction being necessary by reason of the fact that the magnetic flux, due to the field magnet winding, is alternating.

The polar projections or pole pieces, 19, are provided with holes or perforations, 20, extending through the same, transversely to the direction of armature rotation, and located in close proximity to the ends of the polar projections or pole pieces, and the depth of the body portion of the core is reduced at the rear of each polar projection, as shown at 181, in Figs. 7, 8 and 9, in order to aid in reducing the cross-magnetization and, consequently, the armature self-induction. The slots, 20, are made comparatively shallow in order to keep the iron loss low and at the same time to insure the desired saturation of the adjacent iron when the current materially exceeds the rated amperes of the motor. These slots may be entirely closed at the pole faces, as indicated in Figs. 7 and 8, or they may have narrow openings, as shown in Fig. 9, but in every case where open slots are employed the openings should be small. As shown in Fig. 7, there are eight of the holes, 20, which, as above stated, are of such dimensions and so spaced as to provide a cross-section of metal between them which will become quickly saturated when the current in the field magnet windings materially exceeds the rated amperes for which the motor is designed. In Fig. 8 are shown six holes, 20, and at approximately the middle of the pole piece is a hole, 21, which is of materially greater depth than the holes, 20. In this hole, 21, is located a bar or plate, 22, of copper or other good conducting material, for the purpose of serving as a closed secondary circuit to reduce the armature self-induction due to the cross-magnetization. In Fig. 8 is shown a plate, 23, of copper or other good conducting material, which also acts as a secondary closed circuit to oppose any cross-magnetizing flux which tends to pass outside of the core, 18, of the field magnet. In Fig. 9 the construction is the same as that shown in Fig. 8, except that a single turn, 24, of wire constituting a closed coil is placed in the middle slot, 21, instead of the bar or plate, 22, and the plate, 23, is omitted. Other forms of conductors suitably disposed to act as secondaries and thus oppose the cross-magnetizing flux might be employed, if desired, those shown being set forth merely as examples that I have found well adapted for the purpose. The field magnet winding, 25, is here shown as comprising eight coils of strap copper, bent edgewise and connected in series and so insulated and supported as to perform the functions desired, and, at the same time, be effectively insulated and occupy a minimum amount of space. In the present case the winding comprises 20 turns, one-half of the coils having three turns and the other half having two turns, and the coils of the two sets are alternately disposed around the core. A greater number of turns may be employed, if desired, provided they are so connected that the number of turns in series does not materially exceed that specified above.

The field magnet core and coils are mounted in a casing, 26, which is provided with extensions at its ends to enclose also the armature and commutator. As shown, this casing projects inwardly, at the backs of the pole pieces, to constitute supports for the core, 18, and is correspondingly hollowed out as regards its exterior, as indicated at 27, so as to lessen the weight of the structure. This form may be varied from what is shown, if desired, and the points of support between the core and the casing may be otherwise located. The casing may also be made of openwork skeleton construction, if desired, since its office is mainly that of a support for the field magnet.

Various methods of controlling motors, constructed in accordance with this invention, may be employed, it being preferable, as above stated, to vary the e.m.f. applied to the motors. For this purpose a transformer may be interposed between the motor and the supply mains, and the e.m.f. of the secondary may be varied by varying the number of windings of the primary or secondary, or varying their magnetic relationship in a manner well known in the art. Either a two-coil transformer or an autotransformer may be employed. Another very convenient means consists in the employment of a three-coil transformer, the third coil of which is connected with the primary coil of a second transformer, the secondary coil of which is in series with the secondary coil of the main transformer, as above described. Rheostats or similar adjusting means may obviously be employed in addition to or instead of the means for varying the voltage. It will be understood, however, that the invention is not limited to the method of control or restricted to any precise method.

The claims of the patent are as follows:

1. A single-phase, alternating-current, series-wound motor, in which the ratio of the field magnet self-induction to the armature counter e.m.f. is approximately equal to the ratio of the line alternations to armature alternations, substantially as described.

2. A single-phase, alternating-current, series-wound motor having a closed-coil, parallel-wound armature with relatively high resistance leads connecting the armature coils with the several commutator bars, and a field magnet the poles of which have slots transverse to the direction of rotation of the armature and with or without a closed conductor inserted in one of the slots and extending through approximately the central portion of the pole, substantially as described.

3. For use with single-phase alternating electric currents, a series-wound motor having the ratio of the number of its field poles to the number of current alternations per minute approximately as 1 to 250, and having a ratio of field ampere-turns to armature ampere-turns approximately as 20 to 27.

4. Electric motors for use with single-phase, alternating currents constructed substantially as described with reference to the accompanying drawings.

Extensive Train Lighting.

President Mellen, of the New York, New Haven & Hartford Railroad Company, has issued orders to the traffic department to equip a vestibuled train with an electric lighting plant, with generators on the car axles. It is stated to be President Mellen's intention to replace gas with electricity all over the line, and this progressive plan is to be put into operation at once.

A Manacled Inventor.

A most extraordinary and almost incredible yarn comes to us from New England, about Henry K. Goodwin, alleged to be held in bondage by the machinations of the Bell telephone interests. A bill is up in the legislature which, if passed, would result in the release of Henry K. Goodwin, now in Charlestown State Prison, who was convicted of the murder of Albert D. Swan, of Lawrence, in 1885. In the process of the hearing Senator Callender, of Boston, astonished the committee and the spectators by asking Lawyer Rowley, who represented Goodwin: "Haven't the electrical corporations in this State opposed Goodwin's pardon?" Mr. Rowley replied: "In my opinion the electrical corporations have done everything in their power to prevent the pardon of Goodwin. And there is in existence correspondence which will show it." "Didn't Goodwin invent a switchboard which is substantially the one now in use by the Bell Telephone and New England Telephone Companies?" demanded Senator Callender, and Mr. Rowley answered: "I understand that to be the case." It would be very interesting to know what kind of a board Goodwin invented, if he ever did invent one.

Discussion on A. I. E. E. Papers on the Single-Phase Railway Motor.

Owing to the great interest of the subject, we supplement our report last week of the January meeting of the American Institute of Electrical Engineers with the discussion in full by Messrs. Lamme, Steinmetz and Armstrong, and the non-mathematical part of the remarks of Prof. A. S. McAllister.

LAMME DISCUSSION.

In the paper presented before the American Institute in September, 1902, I called attention to the fact that there were but two types of single-phase, alternating-current motors having suitable characteristics for railway service, viz.: that called the "series type," and the "repulsion type." Both of these motors have armatures like direct-current motors with commutators and brush holders. Attention was called to the fact that both motors have suitable characteristics for railway service, as both automatically give variable speed characteristics with changes in load. That paper primarily described a single-phase railway system, and the motor formed but an element in the general system. It was a very general opinion at that time that the success of the commutator type of motor for large sizes as doubtful, and the sparking feature was considered a fundamental source of trouble. It was generally conceded that if a motor with series characteristics could be made to operate successfully, it would be a great step in advance in the railway field. Since that time single-phase railway systems have been more fully developed. Practically no departures from the general system then indicated have been furnished, and the types of motors developed have been along the lines of the two motors indicated in that paper.

Up to the present time the only suitable motors suggested for this work have been of the commutator type, and have been those having series characteristics. I have suggested that all these motors can be considered broadly under the one class of series motors, as they all have the series characteristics of the direct-current series motor. I further suggested that they can be subdivided into the "straight series" type and the "transformer series" type. The transformer series could also be arranged in two classes, viz.: one in which the armature or field is supplied by an external transformer, and one in which the transformer is placed in the motor itself; this latter is the repulsion type of motor.

Figs. 1, 2 and 3 illustrate the three classes, Fig. 1 being the straight

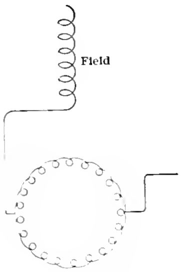


FIG. 1.

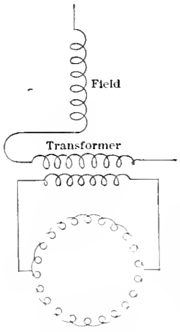

FIG. 2.

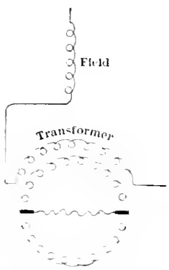

FIG. 3.

series, Fig. 2 the transformer series and Fig. 3 the repulsion motor. Fig. 2 would be considered as a true series motor, although the armature and field are not directly in series, and yet most of the characteristics described as belonging in the repulsion motor apply directly to the transformer motor shown in the figure. Comparing the relations of these motors, viz.: the straight series and the repulsion motor, we will first take up the straight series.

In this motor, if properly designed, two voltages can be considered, viz.: that across the field circuit, and that across the armature circuit. The armature voltage can be made practically non-inductive so that the input of the armature will represent practically true energy. The voltage across the field is practically at right angles to the armature voltage, and represents very closely the wattless component supplied by the motor. The resultant of these two voltages will then be the line voltage. The power factor of the motor when running is represented principally by the voltage across the armature winding being increased slightly by the losses in the field core and winding. Therefore, for high power factors it is important that the voltage across the armature circuit be made as high as possible, relative to the applied voltage, and that across the field as low as possible.

There are three ways in which to increase the voltage across the armature, viz.: by increase in speed, by increase in the number of wires in series in the armature, and increase in induction through the armature. By increase in speed and increase of the wires in series, the armature voltage will be increased without affecting the field voltage, and therefore the ratio of the armature voltage to the line voltage is increased. Increasing the induction in the armature also increases the induction in the magnetizing coil in the field, and the voltages of both are increased. Therefore, this increase does not improve the power factor of the machine.

Instead of increasing the armature voltage, the voltage across the field winding may be decreased for improving the power factor. This can be decreased in two ways, viz.: by reducing the turns in the field coil or by reducing induction through the coil. Reducing the induction through the field reduces the induction in the armature winding also, and therefore represents no gain; and, therefore, reduction in field turns is the feasible means of reducing the field voltage. Reduction in field turns can be accomplished in two ways, viz.: by decreasing the effective length of air-gap in the motor, and by increasing the cross-section of gap. By making the gap very small the voltage across the field could be made very small compared with the line voltage, and extremely high power factors could be obtained, whether the motor is of the straight series or repulsion type. Also by increasing the section of the air-gap the turns of the field can be decreased with a given total induction through the coil, and the power factor can thus be very considerably increased. The first method, viz.: decrease in gap, is limited by practical conditions, which have been determined from long experience with direct-current work. It should be borne in mind when published descriptions of such motors are given that the results, as regards power factor, generally depend upon data which is not given in the description, such as the magnetic dimensions of the armature and field, the length of gap, etc. Therefore, a machine may be described as showing an extremely high power factor, which may in practice not be a commercial machine, from the standpoint of American railway experience. Increasing the section of air-gap without decreasing the length of gap also improves the power factor, but makes a larger and heavier machine, as a rule.

Both these modifications reduce the ampere-turns in the field. The direction of the improvement in the armature was shown to be in increased armature ampere-turns with a given speed. It therefore follows that almost any result desired can be obtained as regards power factor by increasing the armature ampere-turns and decreasing the field, or exciting ampere-turns. I will refer to this point in considering the repulsion motor.

It should be noted that in all these motors there should be but little saturation in the magnetic circuit, and but few ampere-turns expended in saturation of the iron under normal conditions. This consequent low saturation in such motors leads to certain characteristics in the torque curves which have been cited this evening, as an indication of superiority of the alternating-current motors over direct-current motors, namely, a torque increasing approximately as the square of the current. In fact, this superiority of torque should be charged to the non-saturated condition of the motor rather than the alternating-current principle. If direct-current motors were worked normally at as low induction as the alternating-current motor, then the direct-current motor would show better torque characteristics, which would be comparable with the alternating motor. This claim for a better torque in the alternating motor compared with the direct seems to be a case of making a virtue of a necessity.

It is evident from what has been said that the power factor of the straight series motor can be made anything desired, it being a question of proportion between armature and field, length of air-gap, amount of material used, etc. In practice a compromise would naturally be made among the various characteristics, and a slight reduction in power factor is probably of less importance than a corresponding reduction in size and weight. Also large clearance is probably of more importance than an extremely high power factor at normal load. In practice it will be found that such motors are made with armatures with a large number of ampere-turns compared with the fields in order to obtain comparatively high power factors with large air-gaps. The number of poles need not be made such that the produce of the poles by the normal speed represents the frequency of the supply circuit. Good series motors can be made, and have been made, in which the number of poles were very much larger or much smaller than represented by this relation.

Taking up next the transformer type of motors, Fig. 2 represents one type of these. In this the field is in series with the primary of the transformer, the secondary of which is connected to the terminals of the motor. I would call this a true series motor, although it is not a straight series motor. In this motor the voltage across the armature can be made practically non-inductive and the voltage across the primary of the transformer will be practically non-inductive. The voltage across the field winding will have practically 90° phase relation to that across the primary of the transformer, and the magnetic field set up by the field winding will have a 90° relation in time, to the magnetic field in the transformer, as in the repulsion motor. In this motor the voltage across the transformer will be highest at light loads and will decrease with load until zero speed is reached. At start there is lowest induction in the transformer and highest induction in the field winding. Such a motor will have speed torque characteristics very similar to those of a straight series motor, except as affected by the actions taking place in the transformer itself. If the transformer possesses no reactance, then at start the current in the armature should be the same as if connected as straight series motor, and the conditions of torque at start should be the same. If the transformer possesses reactance, then at start the current in the armature will not be quite equal to the current which the armature will receive if coupled as a straight series motor, assuming the transformer to have a 1 to 1 ratio. Neither will the armature current be exactly in phase with the field current; therefore, the starting torque of a motor connected in this way will be slightly less than the torque of the same motor if connected in straight series. This is on the assumption that the transformer is one proportioned for small reactance; but if the primary and secondary windings of the transformer should be on separate cores with air-gap between, then the reactances of the windings are considerably greater than in the above case. Therefore, we should expect a motor with such a transfer would give still lower torque than the straight series with the same current supplied from the line.

In a repulsion motor the transformer is combined with the motor itself and the primary and secondary windings are upon different cores with an air-gap between. The starting conditions of such a motor as indicated above should be poorer than the straight series motor, or for the same starting torque somewhat greater apparent energy should be required. It stands to reason that applying the current directly to the armature winding should give greater ampere-turns and better phase relations than generating this current in a secondary circuit, and not under ideal transformer conditions. The tests which I have made, as well as the results shown in the curves of the papers given to-night, indicate this. It is to be noted that the torque curve is not the same shape near the zero speed point as the torque curve of the series motor.

Series motors and repulsion motors may be indicated in the simple form shown in Figs. 4 and 5. In the diagrams of the repulsion motor (Fig. 5), two field poles, *F F*, are shown, and two transformer poles, *T T*. To obtain high power factors on such a motor the ampere-

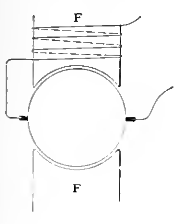

FIG. 4.

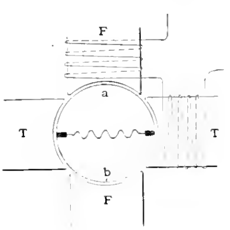

FIG. 5.

turns in *T* must be much greater than in *F*, which means that the ampere-turns in the secondary or armature are much greater than in the exciting field, as in the series motor. The high power factor obtained with these motors is, therefore, due principally to the small ampere-turns in the field and the small voltage across the field.

With brushes set at an angle of 16°, for instance, from the primary or resultant field, the ratio of armature to exciting field turns would be almost 5 to 1, a ratio which will also permit of extremely high power factors in well designed straight series motors over wide ranges of speed. To this feature should be credited the good power factors claimed for the repulsion motor. In either the series or repulsion type of motor, high power factors, especially at low speeds, are directly dependent upon this fact of high ratio of armature to field, and with a high ratio, high power factors should be obtained without crediting the result to leading currents in the armature. In the diagram of the repulsion motor the line current indicated flows through to the field winding and the transformer winding. The primary current sets up a magnetic field in the exciting windings in phase with the line current. If it also set up a field in the transformer in phase with the line current, then the e.m.f. generated in the armature winding due to rotation would have a 90° relation to the e.m.f. set up by the transformer, and a correcting or magnetizing current would flow. This flow is in such direction that it corrects the relation between the two voltages in the armature by shifting the transformer magnetism one-quarter phase later than the exciting field magnetism. This armature corrective current thus may be considered as magnetizing the transformer, making the primary input to the transformer practically non-inductive, but this magnetizing or correcting current may be considered as flowing in a circuit at right angles to the field magnetic circuit, and having practically no effect on the field circuit. Therefore, as a rough approximation, the exciting field may be considered to represent the wattless component of the input, and the transformer field the energy component, as in the series motor.

As to the statement that the magnetizing current in the armature reduces the wattless component of the exciting field, I do not accept it broadly. If this component is reduced, then another component of practically equal value is introduced somewhere else, for the power factors obtained with such motors can be accounted for by the high ampere-turns in the armature winding, compared with the field or exciting ampere-turns. If the armature current improves the power factor by diminishing the magnetizing or exciting field, then the curves in curve sheets 1 and 4 of Mr. Slichter's paper should show it. I have gone over both sets of curves calculating

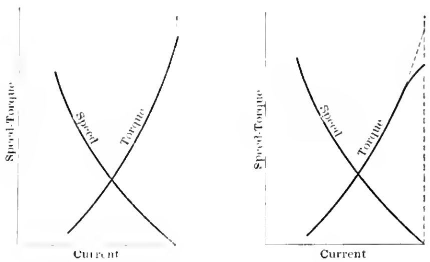

FIG. 6.—SPEED-TORQUE CURVES.

the wattless components from the power factors. From this and other data in these curves I find that beginning near synchronous speed the wattless component in the motor goes up slightly faster than would be represented by the field excitation, assuming it to be entirely wattless. Therefore, according to these curves, the power factor at lower speeds are not quite as good as would be obtained by a field entirely inductive and the armature entirely non-inductive, in a straight series motor. These calculations are rather approximate, as the curves do not check at all well with each other. For instance, the output of the motors is represented by the input multiplied by the power factor and the efficiency. The output is also represented by the product of speed by torque. These two results do not check at all well in either set of curves, there being discrepancies as high as 10 per cent. In curve sheet No. 4, for instance, either the torque or the speed is too high for the lower speeds. Checking back on this curve, using either the speed and torque or the power factor and efficiency for determining the output, I find that the wattless component in the motor at 190 revolutions is approximately 20 per cent. higher than it would be if the field excitation alone were wattless, assuming at 440 revolutions the wattless component is represented purely by field excitation; that is, from 440 to 190 revolutions the wattless component is increased 20 per cent. over that which would be represented by field excitation alone. This indicates that not only should the field excitation be considered as practically wattless, but that in addition there is a wattless component due to reactance in the armature widings, etc.

The armature current can be split into two components, one of which is partly magnetizing and represents no torque. The other component is in phase with the field magnetism and, therefore, represents torque. The magnetizing or wattless element may be comparatively small, as the number of turns in the armature is relatively large, but the armature thus carries at times a slightly larger current than the straight series motor.

A further inspection of the diagram (Fig. 5) indicates how the power factor of the motor can be made very high at synchronous speed. At all speeds the voltage generated in the armature due to rotation in the field *F*, is practically equal to the voltage generated by the transformer *T*, thus making zero voltage across the terminals. But also at synchronous speed the voltage generated by the exciting field acting as a transformer, between the points *a b* will be practically equal to the voltage generated in the winding by rotation of the winding in the transformer field. Therefore, across *a b* the voltage is practically zero with these conditions, but the frequency remains the same as that in the field. If now the magnetizing current be supplied across the points *a b*, then the required ampere-turns for magnetizing the motor can be supplied at practically zero voltage, and the turns of the external magnetizing field can be omitted. Therefore, under this condition the wattless component is practically zero and the power factor becomes practically 100 per cent. This is the method of excitation used on certain European single-phase motors in which high power factors are claimed for full-load running. But this method of excitation does not improve conditions at start as the same excitation will be required at standstill, whether the excitation be supplied to the armature or to the field. Therefore, this method of excitation does not help the motor at that condition of load which is the severest on the generating and transmission system. It has the advantage of omitting the field exciting winding, but has the great disadvantage of requiring a double set of brushes on the commutator with but half the distance between the brushes found in the straight series or the ordinary repulsion motor. I do not believe that such methods of compensation are of sufficient advantage to overcome the complications attendant upon them.

At zero speed both the straight series and the repulsion motors will show low power factors and with equal losses in the motors the repulsion should have slightly lower power factor than the series. This question of power factor at start is largely a question of internal losses in the motor at rest, and the repulsion motor in individual cases may show higher than the series motor, because it may be designed with higher internal losses. The real measure of effectiveness is not the power factor at start, but the apparent input or kilovolt amperes at start required for a given starting torque. With equally good designs of motors, my experience is that the kilovolt amperes will be found to be considerably less with the straight series than with the repulsion motor, due to the fact that the current is fed directly into the armature and not by transformer action, and, therefore, the conditions of phase relation and amount of current in the armature winding are more favorable. Therefore, it follows that in order to have the same kilovolt ampere input for the same starting torque, the repulsion motor should have a smaller length of air-gap than the corresponding straight series motor, or should have a greater section of air-gap, which means greater weight of motor. This is one of the conditions which has led me to the advocacy of the series motor rather than the repulsion motor, as I have considered this condition of starting of more importance than running, although I am satisfied that many of the running conditions of a well-designed series motor will be found in practice to be superior to those of an equally well designed repulsion motor.

Referring again to Fig. 5, it will be noted that two fields are set up in such a motor, and that at synchronous speed these two fields are equal. In the straight series motor there is but one field set up, the other being omitted. It is evident that the straight series motor with the current supplied directly to the brushes can have a smaller section in certain parts of the magnetic circuit than is required for the repulsion motor, and that, therefore, the weight of material would be less, and the external dimensions can be less. Therefore, it follows that for equally good designs and same frequency, the straight series motor should be more compact and should weigh less than the repulsion motor. It is reasonable to expect this, as the repulsion motor contains a transformer in addition to the other parts found in the straight series motor. Furthermore, the transformer found in such a motor is one with an air-gap and with the windings on two separate elements, and, therefore, cannot be as well proportioned as a separate transformer could be. Also, there is a transformer for each motor, and in a four-motor railway equipment, for instance, there would be four transformers of smaller size against one larger transformer used with the series motor, this larger transformer having a closed magnetic circuit, and of a highly efficient design compared with the transformers in the motors themselves.

A further point should be taken up in the comparison of these motors, viz.: the current in the coil short-circuited by the brushes. This coil is a secondary to the field and the current in it is necessarily greatest at the period of strongest field. Therefore, this current will be greatest at the time of starting. If the repulsion motor and the straight series motor have the same field strength at start, then the short-circuited current should be the same in each. But as the current is fed into the armature in the repulsion motor through transformer action, it will be found as a rule that the starting field strength of such a motor is slightly greater and the starting armature strength slightly less for a given torque than is found in the straight series motor having same ratio of armature to field windings. Therefore, the short-circuit current at start will be somewhat larger for the repulsion motor than the corresponding staight series motor. This short-circuit current may be somewhat less near full speed than in the straight series motor, but it is not the full speed condition which is the serious one. The short-circuit current at start is one of the most serious conditions which confronts us in alternating-current motors, and is also of great importance where there is any considerable operation on low speeds, and I have advocated a type which I consider gives the easiest condition in this regard. This short-circuiting cannot be entirely

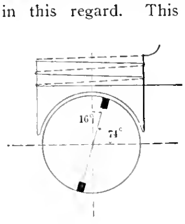

FIG. 7.

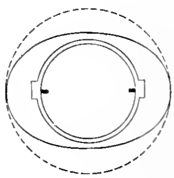

FIG. 8.

avoided in any of the motors brought out without adopting abnormal and questionable constructions, although devices like narrow brushes, sandwich windings, etc., have been proposed. In certain foreign motors the brushes used are so narrow that they cover practically the width of one commutator bar. As such motors are generally built with a very large number of bars, the brushes used are extremely narrow, being approximately 0.2 in. thick at the tip. This will undoubtedly lessen the short-circuiting, but I consider that it is simply transferring trouble to another point, and not avoiding it. A brush 0.2 in. thick is not a practicable one for commercial railway service. At higher speeds, with only a moderately rough commutator, such brushes will be liable to chip and break. I have had experience with ¼-in. brushes on such high-speed commutators and speak from experience. Further, I do not believe that the brush on a street car motor should be so narrow that it bridges but one commutator bar. A brush should bridge at least two bars to give good smooth brush operation. I have made a practice of using ½-in. brushes on motors of say 100 hp.

The sandwich winding, which consists of two or more windings side by side, will prevent short-circuiting at the brushes, but is another case of transferring trouble to another point. It has been found in practice that it is difficult to run a sandwich winding without trouble at the commutator with direct current without a tendency to blackening and pitting of the commutator and I consider that with alternating current this tendency to pitting and burning of the bars would be equally great.

As a rule, I have found little difference between the operation of repulsion and straight series motors as regards sparking, except that the repulsion motors generally have greater current in the short-circuited coil near zero speed, and, therefore, show greater tendency to heat and spark. At or near synchronous speed there appears to be very little difference in the commutation, although I have never given the repulsion motor the test of long-continued service that I have given the series motor. The series motors with which I have worked have never shown any tendency to give trouble on the commutator, and on the exhibition car equipped with four 100-hp motors, the commutators have never been sandpapered since the equipment has been put into service. This exhibition car is used principally for showing the accelerating properties of the motors. I have, therefore, no hesitancy in saying that the straight series motor will prove to be equal to the direct-current motor as regards action at the commutator. Wide brushes are used, such as have been used in street railway motors.

It is well known that with large direct-current motors, especially where operated at very high speeds, there is a tendency to flash across the commutator, or to the frame of the motor if the field circuit be opened for a period long enough to allow magnetism to drop to zero, and then the field be closed again. In this case there is a rush of current before the field has had time to build up, and this rush of current, together with field distortion, may cause serious flashing. In the alternating-current motor, whether of the straight series or the repulsion type, this tendency should be entirely absent. In the straight series motor the magnetism falls to zero once in each alternation, and, therefore, if this tendency to flash existed it would occur continually. The lamination of the magnetic structure and the proportions of the machines which permits it to operate successfully on alternating current tend at once to cure this trouble from flashing found in direct-current motors. Furthermore, a properly designed straight series motor can be short-circuited across the brushes without injury to the motor, and can continue to operate in this way. Therefore, if the machine can be short-circuited in this way, there is no tendency to maintain an arc if suddenly short-circuited.

Returning to the subject of power factors, it should be noted that high power factors are very frequently found in motors of low or only mderately good efficiency. This low efficiency, to a slight extent, explains the high power factor in some motors, both polyphase and single-phase. Low efficiency means higher true energy expended, and with a given wattless component it means higher power factor. It is the old problem of increasing the power factor by wasting energy in a circuit instead of reducing the wattless component. The power factor of any alternating motor can be very considerably increased by putting resistance in series with it. Instead of this resistance the internal losses of the motor may be made higher, which will accomplish the same results. The motor will, therefore, appear to have a higher power factor than it really deserves, if efficiency of the motor is taken into account. If, for instance, the efficiency at 300 revolutions shown in Mr. Slichter's curve sheet 4 would be made as high as on direct-current motors, then the power factors with the same magnetizing and other conditions would have been approximately 4 per cent. lower. This lower power factor would not have made any harder condition on the supply circuit, but actually would have made a somewhat easier condition, as the supply system would have furnished about 8 per cent. less kilovolt amperes. For lower speeds this difference in power factor will be greater, and less for higher speeds. A high power factor at start, obtained by the use of resistance in series with the motor by high internal losses which do not represent torque, is, therefore, a detrimental condition rather than a good one, as it means increased kilovolt ampere expenditure for a given torque. This is merely given as an illustration showing that power factor in itself is not a true indication of conditions, but must be accompanied by other data. I do not give this as a criticism of these motors, but as a general condition found to a greater or less extent in all alternating motors.

STEINMETZ DISCUSSION.

In opening his discussion Mr. C. P. Steinmetz said he was pleased to agree with Mr. Lamme in considering the relative position of the repulsion motor, the plain alternating-current series motor, and the alternating-series motor fed by a transformer; and that he was pleased to see that Mr. Lamme has come to the same conclusion to which he and Mr. Eickemeyer had come in this early work; that is, that the only way to make an alternating-current series motor to operate at reasonably satisfactory power factor was to combine as high armature reaction as possible with as low field excitation as possible, then increasing the ratio of armature magnetism to the field, thus eliminating the current you cannot use; otherwise one will strike a standstill. As to assuming that the alternating current is non-inductive, no electrical engineer has yet designed a circuit traversed by alternating current which is really non-inductive. In the early work of Mr. Eickemeyer careful investigation was made on this subject by having the motor designed so that the relationship between the armature magnetic force and the field magnetic force could be varied, and it was found with that particular motor, using ratios somewhere between 3½ and 4, that is, where the armature reaction was between 3½ and 4 times greater than the field action, the best condition was reached. That is to say, if the total induction increases the armature reaction beyond that we lose more by increasing the induction of the field. With a short-circuit surrounding the armature, this point was reached at the lower value of armature reaction. However, that work was done at very high frequencies; that is, with motors where the polarity pitch was much less than they must be with the present frequencies, and undoubtedly with a change from these high frequencies of the early days to the frequencies considered here, which are about a quarter or less than those old frequencies, we can go to a further extent in this direction. However, attention is called to the fact that there is an ultimate limit between the ratio of armature reaction and the field excitation; otherwise you could say you could, by making the armatures 100 times as strong as the field, get any unit of power factor practicable; but you reach a maximum point and you cannot go beyond that without losing again.

The fact is that the repulsion motor has inherently such a high power factor that even with a considerable air-gap an air-gap which is impossible with the ordinary induction motor we can run to magnetic saturation and with large starting current; this magnetic saturation is approached and passed in part of the magnetic structures, in the base of the field and armature, and that causes the falling off, as we observe in the direct-current motor. It is not feasible to go to anywhere near such saturation as in the direct-current motor, but while we approach saturation, it is not necessary, but means a small motor.

Regarding the relative proportions and material of the repulsion motor and the alternating-current series motor, Mr. Steinmetz agreed with Mr. Lamme as far as his conclusion goes; that is, by using one and the same motor, the alternating-current series motor, first as a series motor and then as a repulsion motor—and experimental investigations have been made in that direction—by using a repulsion motor and running it as an alternating-current series motor led to exactly the opposite result, that the series motor is decidedly larger in weight and lower in efficiency. The explanation is simple. One reason why that the armature is not absolutely non-inductive, and the result is that if you calculate the power factor from the inductance of the field, assuming the armature is non-inductive, you get a higher power factor than exists in reality, because there is a self-inductance in the current of the primary and secondary, and self-inductance in the armature. While small, it is still there. You will find it in all alternating-current systems. Both observations are, no doubt, right, but in the repulsion motor by using this transformer we derive a high power factor at relatively low speeds and thereby are permitted to apply the standard induction motor design; that is, the distributed winding—the primary winding or field winding being distributed around a circumference—the secondary winding meaning low inductance winding. The induction motor has been made a commercial apparatus only by going to the distributed winding, but induction motors are still built and operated with definite polar projections, but they are inherently lower in power factor than motors with the distributed winding. By applying the same principle to the repulsion motor, we get thereby a considerable decrease in the self-inductance of the circuits and thereby are permitted to get close to saturation, in turn reducing the size and weight. Such a winding, however, for a plain series motor is not satisfactory, because in the series motor, as the original investigations of ten years ago showed, it is essential to have a definite polar projection to get good power factor, so that the motors considered, while they are a development of the same type, are of an entirely different mechanical structure. A motor which is a good series motor will make a very poor repulsion motor; the repulsion motor is larger, heavier, and more efficient. You cannot take one and the same motor and run it first as one and then as the other and draw general conclusions, because the transformer feature introduced requires redesigning and nullifies comparisons based on one particular design.

Mr. Steinmetz said that comparing the present alternating-current motor of the plain series or repulsion type with the highly developed direct-current motor, we find a somewhat lower efficiency in the alternating-current motor, and it has somewhat larger weight. His personal opinion is that the difference is altogether less than should be anticipated, considering the short time of the development of the one and the longer time of the development of the other. The two types are not directly comparable. Take, for instance, the question of weight. In the direct-current motor we must have definite polarity, which requires a larger radial depth and a distributing winding of the repulsion motor, hence the outer turn of the field structure would be impossible in the repulsion motor and with the same external diameter there must be larger diameter in the repulsion motor. This throws out a direct comparison. As to the question regarding the relative efficiency, the internal proportioning of the motor is different. In the modern direct-current series motor the field is much stronger than the armature; in the repulsion motor we have realized a condition where the armature is stronger than the field. That would mean to correspond to the direct-current series motor in which we quadrupled the output of the armature, having four times as many turns. That would throw out of proportion any comparison to give the relative efficiencies; so, while the alternating-current motor has the additional losses of the hystereses and eddy currents, the proportions are changed and we cannot say that it means inherently low efficiency any more than we can say that the polyphase induction motor means a lower efficiency than the direct-shunt motor. We know that this is not the case, but that the polyphase induction motor has the same efficiency as the direct-current shunt motor on a general average. While at present for some years to come the alternating-current railway motor, as a new type of apparatus, will be handicapped by somewhat lower efficiency and somewhat greater weight, he does not consider this as inherent to the motor, but rather as more or less the result of a shorter development and does not consider it impossible that they should come to equality with, or even in some cases superiority to, the direct-current motor; but that is merely guessing at the future. All that he can say is that he does not see any inherent reason why the alternating-current motor should be heavier or less efficient than the direct-current motor. As to reversing, there are different ways of doing the same thing. We can change the point of entrance of the current in the primary wire without changing the brushes. We can feed into the primary winding at several different points in the repulsion motor and get the advantage of not shifting the brushes. As to whether it takes more copper in the repulsion than in the series motor, the repulsion motor takes more copper and less iron than the direct-current series motor takes, because the proportion of armature to fields are reversed as to the alternating-current series motor. He did not want to state positively, because he had not gone over the fields of the alternating-current series motor with sufficient care, or tested the ordinary current series motor with modern frequency; but his impression is it would be about the same as the direct-current motor. The plain series motor will have a smaller armature diameter than the repulsion motor, probably larger external diameter, more iron and less copper, but in general he does not expect there will be any inherent difference between the two types.

ARMSTRONG DISCUSSION.

In reply to questions by Mr. Ralph D. Mershon, Mr. A. H. Armstrong said that as to designing a repulsion motor that at the same time will operate as a good direct-current motor, one can make a repulsion motor to operate on direct current good enough to help through a town along right of way, but cannot make a good repulsion motor and a good direct-current motor in the same structure, any more than one can make a good series motor both alternating and direct. One feature or the other has to be sacrificed, and the preponderance of interest will determine which. As to the potential of the motors, a good repulsion motor can be wound for two or three thousand volts on the field without the use of transformers; the exact voltage is open to experimenting. Nothing is known about the effect of constant jarring and crystallization of insulation at high potentials on a railway car. Control can be either by a compensator or resistance or some method like that, with a good potential in starting—there are a number of methods. Such control would hardly be used at high potentials in service calling for frequent stops. If you stop once in five miles the slight difference in efficiency in starting would have no effect on the general efficiency of the system as a whole. You would gain one or two per cent. in the average of the car or train, which would not compensate for the complication. One can consider two or three thousand volts entirely feasible on the field of the motor without any intervening machinery. That, however, is open to experimentation and development. So far as the motor goes, it can be wound to that potential, but whether that motor would successfully withstand the shocks of railway service is a matter to be found out.

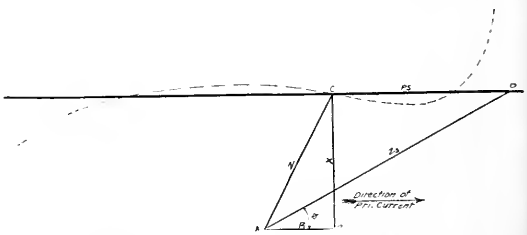
As to the weight of alternating-current motors and direct-current motors, that is an open question. The question of the capacity of direct-current motors has been very carefully worked out by the different engineering companies during the last two or three years, much time and labor has been spent in determining their exact capacities for a given piece of work, standards have been adopted and the matter has been worked down to a fine point with relation to direct-current motors; and to attempt to compare a piece of apparatus not yet in commercial service with a standard piece of apparatus developed for fourteen years, is hardly fair, and it is almost impossible to give a definite answer to the question. It can be said roughly that the motor will weigh somewhat more than the direct-current motor, but just how much added weight there will be we do not know. As to the weight of the rest of the equipment, that would depend on the method of control. If you use a high-potential motor, 3,000 volts direct on the field, your control should not weigh very much more. If you use a low potential and install a transformer of 100-kw capacity in the car, you have the added weight of the transformer in addition to the translating apparatus.

In reply to a question as to how large an alternating-current motor we can get for a 33 or 36-in. wheel, Mr. Slichter said that a 100-hp motor could be placed there, but he could not say a larger motor could not be. Mr. Lamme said his company was building 150-hp motors which will go in on 33-in. wheels closely, easily on 36-in. wheels. They have determined that they cannot put 200-hp motors on 36-in. wheels. That is one limit.

MCALLISTER DISCUSSION.

In introducing his remarks Prof. A. S. McAllister, of Cornell University, said that in the papers presented mention is made of the fact that the repulsion motor, when driven against its torque, acts as a generator, and that when the negative speed becomes of a value such that its product with the torque exceeds the internal losses of the motor, the machine will feed energy back to the line. The analytical equations given by Mr. Steinmetz furnish an explanation of the cause for this action on the part of the machine. The equations used may be represented graphically by a simple diagram, which allows of a more ready interpretation than do the equations.

The diagram referred to is given in Fig. 1, where X (the distance BC) represents the combined local (stationary) reaction of both the primary and secondary circuits, the latter being reduced to primary terms. The scale is ohms or volts for one ampere. The heavy line is the assumed locus and the broken line the observed locus. R (the distance AB) is the equivalent stationary resistance effect of both circuits of the motor. Then Z (AC) represents the stationary impedance of the motor, and the cosine of the angle CAB



IMPEDANCE (E. M. F.) LOCUS OF REPULSION MOTOR.

is the power factor at starting. When the motor operates at a speed S, the power component of the apparent motor impedance is increased by a certain value PS $(CD$ in Fig. 1$)$: P being a coefficient depending upon the relative strength of the field which causes the generation of e.m.f. in the armature conductors at speed S, and hence depends upon the position of the brushes. P is here, as in the equations, assumed constant and the e.m.f. for each primary ampere due to PS is assumed to be in phase with the current supplied.

Fig. 1 shows: $PS = R$, the apparent impedance of the motor becomes X; the current is $\frac{E}{X}$ and represents no energy flowing either to or from the motor; that is, the machine is operating as a generator and supplying its own losses. A further increase of negative speed causes the power component of the apparent motor impedance to become negative, indicating that energy is flowing from the machine. This action of the machine was illustrated by curves which were the results of tests of a certain repulsion motor, while other curves gave the calculated performance of the same motor, proper substitution having been made in the equations. Referring to the theory of the repulsion motor, Mr. Steinmetz states that the current which flows locally in the circuit formed by the brush and an active coil tends to a reduction of the power factor at high speeds; which statement Prof. McAllister said may be taken as an explanation of the fact that the power factor observed in the case of high speeds is much below that calculated, as shown by the curves just referred to. The neglect of the counter torque due to the local current flowing in the coil under the brush leads also to error in assuming that the repulsion motor tends to increase indefinitely the speed of its rotor as the applied e.m.f. is increased or as the load is decreased, since in reality experiment shows that the rotor tends to reach a certain speed above which, if it be driven mechanically, it acts as a brake.

Prof. McAllister then deduced certain equations, and said that the discrepancies between the assumptions made and the physical facts involved will be evident from a study of the formation of these equations, which become identical with the approximate equations of Mr. Steinmetz if for each value used above there be substituted given equivalents.

Modern Methods of Operating Machine Tools Electrically.

Before the Engineering Society of Columbia University on Tuesday, February 2, Mr. Putnam A. Bates, an engineering graduate of the University, and well known as connected prominently with the management of the Crocker-Wheeler Company, gave an interesting lecture on "Modern Methods of Operating Machine Tools Electrically." The lecturer was appropriately introduced by the president of the Society, Mr. Gustav Wittig, and at the close the members expressed themselves as greatly pleased, passing a vote of thanks to Mr. Bates. The general text of the lecture follows:

It is particularly gratifying to the electrical engineer of to-day to note the fact that through the handiwork of his profession in making the use of electricity possible in commercial arts, its adoption has not only become very general, but is looked upon practically as a necessity. The great flexibility, comparatively low cost of installation and economical distribution of electric power, have given it a firm standing in general machine shop equipment. The question, therefore, of whether or not in machine shops power shall be distributed by means of electricity, is to-day hardly considered, as the advantages obtained by this method have been so successfully proven that there is little room left for doubt. Hence, the subject which is given attention is what method of electric distribution shall be adopted and in what manner shall the electric motors be arranged with respect to the work which they have to accomplish.

In considering the subject of individual drive, some have said "that while considered alone and for the individual tool, this method is ideal, yet the objection will occur that the enormous multiplication of small motors means increased complication and greatly increased cost, and that if this method is employed it should be limited to tools requiring from 5 to 10 hp and upwards, and that group drive should be used where the tools require less than these amounts."

If the saving in the coal bill due to the decreased losses in transmission obtained by individual drive throughout a machine shop or factory, only is to be considered, the objection above referred to might in a measure be correct, but as a matter of fact the coal bill in a year amounts to such a small percentage of the total operating expenses of any manufacturing establishment that a small variation in this one way or the other hardly merits more than passing consideration.

The element in our factory costs which requires our most careful consideration is that of the labor cost involved in turning out a given piece of work. A very small percentage of decrease in our total labor bill will, as a rule, justify a greatly increased first cost, provided that cost will directly bring about the reduction of labor. Besides eliminating the disadvantages of line shafting, belting and the inflexibility of location, the individual drive of machine tools by electric motors increases the efficiency and output of machine shops. It is not necessary, therefore, to lay down any specific line of demarkation as to the size of the tool on which it would be advisable to apply an individual motor, but rather to consider in the case of each particular tool the class of work which is to be done and the character of the shop in which the system is to be installed. It can then be determined as to whether the increased facilities which the individual motor-driven tool affords, will not offset the objection claimed against the individual method of tool drive, which is "greater first cost." These increased facilities lie in the direction of variable speeds, under instant control, over any range, with every speed constant regardless of the load, the ability to maintain high cutting speeds due to superior facilities for manipulation and the absence of shut-downs from belt troubles.

If we fail to find that the advantages just mentioned offset the only objection claimed, before dismissing the problem there must be credited against the first cost of the individually-driven tool the cost of countershafts, hangers and belts, also the cost of the increased power to overcome friction losses due to the shafts getting out of line and the tool operator's time lost in lacing and repairing the belts, to say nothing of the unhandy methods which are required for the starting and stopping, and shifting from one speed to another. Upon giving all of these points careful consideration, we will find that the first cost of the individually equipped shop is not much if any greater than one arranged for group drive. Particularly is this so in the face of the advantages obtained by the former method of drive.

The practice of using portable tools and bringing the tools to the work rather than the work to the tools, which is becoming so popular to-day is only a further development of the individually-driven motor tool idea. The portable tool, which cannot be operated unless it is driven by an individual electric motor, serves as an excellent example of what we should endeavor to accomplish in our efforts to make all our machine tools as simple and useful as possible. They should not be so arranged that they must always be in one particular location in a shop, for it may be desirable to use this portion of the shop, as time goes on, for other purposes, or possibly it will become necessary to crowd in additional machines of the same type as those already in use, and it is not every shop that is so arranged as to permit of the installation of additional tools without necessitating very awkward connections to the line shafting.

If the tools are all individually driven, this difficulty does not exist. While the individual method of electric drive provides a material reduction in the cost of power, this factor is not its greatest recommendation, the greatest benefit being derived from the elasticity which is obtained only by the adoption of this method. With individually-driven tools there is no longer any necessity for the rigidity of arrangement which obtains with shafting and belting, so that if it becomes necessary to rearrange the plant at any time, the expense is reduced to a minimum.

The valuable light which possibly the shop or factory building has been constructed especially to provide, can only be maintained by avoiding the adoption of any equipment requiring overhead construction which must necessarily prove a hindrance in this regard. A study of the evolution of the introduction of electricity into industrial plants, first for lights, second for cranes and elevators, third for constant-speed motors for group drive and lastly variable-speed motors individually connected to the tools, indicates clearly that the group method can hardly be compared with individual drive so far as advantages are concerned, or it would not have been necessary for manufacturers to spend their energies in developing the ingenious applications of individual motor-driven tool equipments, which have been offered to the market during, we may say, the past year or so.

While the driving of groups of tools by means of constant-speed belted motors permits of the elimination of very heavy belting and long line shafts, and in this regard is an advance towards the ultimate end—electric drive of individual machines—it does not and cannot offer that which is by far the most important feature of electric drive; i. e., the possibility of placing the speed control of the driven tool at the immediate will of the operator.

With these preliminary remarks as to general problems governing questions which have to be determined before a purchaser can properly select the electric system which is best suited for his own plant, I will pass now to a description of a particular system of electric drive which gives certain positive advantages due to its methods of variable-speed control. The system described is one designed and perfected by the Crocker-Wheeler Company, of Ampere, N. J.

The ordinary belt-driven tool usually has a speed range obtained by mechanical means, of from 20:1 to 50:1, with increased speed steps of about 30 to 50 per cent. The Crocker-Wheeler system for the multiple voltage operation of machine shops not only extends the speed range, but also reduces the speed increment per step to about 10 per cent., which has been found by experience to be as small an amount as would be desirable to use. This system is a method of electric power distribution at different voltages, which enables standard motors to be operated at various speeds by changing the potential of the current at the motor terminals. The generating plant supplies the highest voltage of the system. This voltage may be termed the primary and is divided by a three-unit balancing transformer into three unvarying voltages of unequal value, which are maintained between the wires of a four-wire circuit, various connections of which offer six different and distinct voltages.

The principle of which this system of speed control is based is that in a separately excited shunt motor the speed of the armature is proportional to the voltage supplied to its terminals. If this voltage remains constant the speed will remain constant even with varying load. It is the function of the balancer to maintain these voltages constant and to accommodate the unbalance of currents between the four wires of the distribution circuit. As the conditions of machine tool operation will result in the various motors of the system being nearly equally distributed on the circuits, the unbalanced currents will be but a small percentage of the total current taken by all the motors. The intermediate wires of the system are extended to the variable-speed motors only, the constant-speed and crane motors and the lighting being supplied in the usual manner from the outside wires at the generator voltage.

Those motors requiring variable speed are connected to the four-wire circuit by means of a controller of the drum type adapted for mounting on the tool in a place convenient to the operator. The action of this controller is such that as the drum revolves the armature terminals of the motor are connected in the proper sequence to the six circuits afforded by this system, and the travel of the drum from one position to the next is so quickened by the action of a spring that contacts are made and broken at a high rate of speed, preventing the formation of arcs and eliminating the possibility of the drum stopping between contacts. This gives six fundamental motor speeds, which are subjected to a further refinement by varying the motor's field strength sufficiently to cover the gaps between them.

The speed range obtained on the voltage points alone is 6:1, being proportional to the ratio of maximum to minimum voltages. The addition of field resistance points above the highest voltage points extends the total range of the controller to a value of 10:1. For exceptional cases the range may be increased to a maximum of 12:1, the proper range in any case being determined by the character of the machine and the work which it performs. The Crocker-Wheeler system as outlined has certain positive advantages of which the most important are the following: 1, variable speed, under instant control, over any range; 2, every speed constant regardless of the load; 3, controllers simple and convenient of attachment; 4, the horse-power of the motor but slightly in excess of that required by the tool; 5, output of machine tools much greater than when they are belt-driven; 6, easy of adaptation to existing shops with a two-wire system of electric power distribution; 7, employment of standard motors; 8, ability to maintain high cutting speeds due to superior facilities for manipulation.

Motors used in an ordinary shop equipment may be divided into Classes A, B, C or D, according to the nature of their duty. Class A is the constant-speed motors such as drive groups of small tools by shafting, this class being kept as small as possible consistent with best judgment based on a careful study of all of the advantages which should be credited to the individual drive idea in comparison with the one disadvantage which may or may not exist, that of a possible slight increase in first cost. In many cases, however, even this one disadvantage may be lost sight of in the face of the advantages which are to be obtained through flexibility of location and ease of manipulation. Class B, controllable-speed motors, generally of the series-wound type, as used on cranes. The duties which the motors in both of these classes have to perform is such that their demand for current is intermittent and often excessive, consequently they are best suited for connection to the outside mains and such speed regulation as they may require can be obtained by rheostatic control.

The other two classes, C and D, are controllable-speed motors for the drive of individual tools where the speed should be maintained constant at any one of a number of fixed values. Class C covers driving pressure blowers, punch presses, planers, etc., which demand approximately constant torque at all speeds, the horse-power diminishing with the speed. This characteristic of the tool being identical with the power characteristic of the motor on this system, the normal horse-power of the motor need not be greater than the maximum demanded by the tool.

Class D covers those motors operating lathes, boring mills, etc., where the torque increases as the speed diminishes. If the range required by these tools is to be obtained by using a motor through its maximum range, the motor would be very large and unnecessarily expensive. For this class a speed range of approximately 3:1 has been selected as a basis for the determination of the most suitable sizes of motors with respect to the duty which they have to perform. A motor, therefore, to give a constant horse-power throughout this range, must have a normal rating of about twice the horse-power required by the tool. This range, however, may be extended to cover the entire range required by the tool by using one or more additional gear runs. The method is an advantageous compromise between the use of an excessively large motor with no gears and a constant-speed motor with many gears.

The extreme facility of manipulation which this system affords enables the machinist to push his tool to the highest limit of cutting speed, thereby giving large increases in output. Results show that as much as 20 per cent. increase in output over a belt-driven tool may be obtained by this system of motor drive. As by actual test in commercial plants, it has been demonstrated that 2¼ per cent. increase is sufficient to warrant the outlay necessary for individual drive, the possibility of large saving in operating expenses through the adoption of this system is at once apparent.

Local Meetings of the American Electrochemical Society.

The first meeting of the New York Section of the American Electrochemical Society was held on January 26 in the Chemists' Club, New York City, the attendance being nearly 60 in spite of most disagreeable weather. The first meeting of the Philadelphia Section was held on February 5 in the Engineers' Club, of Philadelphia, the attendance being 11. As far as the papers presented were concerned, both meetings were a full success and the discussion which followed the reading of the papers was in both cases animated.

The meeting of the New York Section was opened by the chairman, Prof. Charles A. Doremus, who dealt with the success of the Society and explained why New York City should have a local section. Mr. A. von Isakovics acted as secretary.

In a paper on "The Commercial Electrolysis of Water," Prof. J. W. Richards gave a review of the various commercial systems for producing hydrogen and oxygen by the electrolysis of water. A solution of caustic soda, with iron electrodes, seems now to be generally used. To keep the products of electrolysis—oxygen and hydrogen—separate from each other is the main technical problem in the design of the cell. This is universally done by means of a diaphragm, but according to the nature of the diaphragm the following three classes may be distinguished: First, non-conducting porous diaphragms filling the whole cross-section of the cell, as in the cell of Schmidt; second, solid partial partitions of a non-conducting material, as in the cell of Schoop; third, metallic partial partitions, as in the cell of Schuckert. In the latter case the metallic partition does not conduct the current, since otherwise hydrogen and oxygen would be evolved at its two sides. This is at least the case as long as the e.m.f. at the terminals of the cell is kept low. Such partial metallic diaphragms are, of course, preferable to glass on account of durability.

In a paper entitled "Thermochemistry of Electrolytic Dissociation," Mr. C. J. Reed attacked a previous paper of Dr. J. W. Richards on the same subject and claimed that his calculation of the neutralization heat was essentially based on the assumption of complete dissociation, which contradicts his other views. Dr. Richards' method of calculating the formation heats, on the principle that it is an additive property, is claimed by Mr. Reed to be incorect in many cases. In the discussion which followed, Dr. Richards maintained his original position concerning the calculation of the neutralization heat and stated that the rule of Hess for calculating formation heats applies essentially to very dilute solutions. It is, of course, well known that this consideration does not apply to the case of insoluble salts.

In a paper on "Ferro Alloys," Mr. A. J. Rossi gave an account of his researches on the manufacture of ferro alloys in the electric furnace and discussed especially his method of reduction by means of aluminum. It is in principle similar to Goldschmidt's aluminothermic method, but while the latter uses aluminum in powdered form, Rossi applies the aluminum in waffles, ingots, scrap or the like, which are charged in the electric furnace. When the current is started, the aluminum melts in a very few minutes, and into this molten bath he then shovels the metallic oxides to be reduced. As applied to ferro-titanium, for instance, the method consists in charging in the bath of aluminum titaniferous iron ores, i. e., titanic oxide associated with iron oxide. Iron is reduced first, forming a bath in which the titanium reduced by the aluminum in its turn dissolves, yielding the ferro-titanium. Mr. Rossi exhibited a very interesting collection of ferro metals, which he had produced in the electric furnace, including ferro-titanium, ferro-tungsten, ferro-molybdenum, ferro-chrome, ferro-silicon, ferro-manganese, copper-titanium with accompanying slags.

A note by Mr. I. J. Moltkehansen referred to an observation which he had made in electrolyzing a concentrated silver nitrate solution with two platinum wires as electrodes. He obtained two deposits of similar appearance at both electrodes. Mr. Reed suggested that the anodic deposit might have been silver peroxide.

The meeting of the Philadelphia Section was called to order by Mr. Carl Hering as chairman, Dr. S. S. Sadtler acting as secretary. A paper on "Composition and Reduction of Voltages" was presented by Dr. J. W. Richards. It relates to the calculation of the e.m.f. in the case when two or more different chemical actions are simultaneously going on. For instance, if a solution of a mixture of copper sulphate and sulphuric acid is electrolyzed between copper electrodes, the question is what must be the voltages at the terminals of the cell. If a certain number of coulombs is consumed in depositing copper, while the balance of the coulombs evolves hydrogen, the energy of both reactions can easily be calculated. (The energy required for depositing copper is, of course, zero as long as the Joulean heat is neglected.) By dividing the total energy required for all the different reactions which go on by the total number of coulombs passing through the cell one gets what Dr. Richards calls the composite voltage. Some numerical examples were given by the author.

In a paper entitled "Formation of Hypochlorites," Dr. S. S. Sadtler discussed some experiments concerning the influence of the composition of a solution and the material of the electrodes on the formation of hypochlorite. The electrolyte was a salt solution containing an alkali and the results were given for different concentrations. He found peroxide of lead electrodes to be the best for his purpose.

In a paper entitled "Theory of Electromotive Forces," Dr. R. Gahl applied in an interesting manner the theory of electrons to the calculation of e.m.f's. The result which he finally reaches is the well-known formula of Nernst for the e.m.f. of a galvanic cell, but Gahl's method is novel in so far as he bases his considerations on the chemical equilibrium between charged ions, discharged atoms and electrons. For instance, in the case of the monovalent sodium ions he considers the chemical equilibrium between the charged sodium ion, the discharged sodium atom and the positive electron.

A brief note by Mr. E. W. Smith maintained that what is generally called overvoltage must be assumed to be contained in the second term of the Gibbs-Helmholtz equation which contains the temperature coefficient. Dr. Gahl doubted the correctness of this assumption since the Gibbs-Helmholtz equation assumes the discharge of the cell to be absolutely reversible, and the reversibility is doubtful for those processes which are concerned in what is generally called overvoltage.

Canadian Niagara Falls Power Development

In a report to the stock and bondholders of the Electrical Development Company, of Ontario, Limited, which has been printed in pamphlet form with a number of illustrations, an account is given of the present status of the work on the power plant being erected on the Canadian side of Niagara Falls, and which, when completed, will generate power for transmission to Toronto.

Vice-President and General Manager Frederic Nicholls gives an account of the organization of the enterprise and the general progress of the work. From this we learn that on January 29, 1903, an agreement was entered into between the Queen Victoria Niagara Falls Park Commissioners and Messrs. Mackenzie, Pellatt and Nicholls, granting rights to take water from the Niagara River at Tempest Point, for the purpose of generating electricity to the extent of 125,000 electrical hp. On the 18th of February, 1903, the Electrical Development Company, of Ontario, Limited, was incorporated under the authority of the Legislature of Ontario, with a capital stock of $6,000,000. At a meeting of shareholders of the company, held on March 21, 1903, the agreement made between Messrs. Mackenzie, Pellatt and Nicholls and the Queen Victoria Niagara Falls Park Commissioners, was acquired by the company.

Since that date no time has been lost in expediting operations in order that the enterprise may be income-producing at the earliest possible period. Contracts have been awarded for cofferdam, tail-race tunnel, wheel pits and electric generators, and preliminary plans have been completed for the construction of the power house. Contracts for the water wheels and head gates have yet to be let, but the engineering data for all of this work is about completed, and tenders will be called for at an early date.

The Toronto & Niagara Power Company, having the charter right to expropriate lands, has been equally active in securing a private right of way between Toronto and Niagara Falls, on which the pole line for the transmission of energy will be constructed. About 85 per cent. of the right of way, having a minimum width of 80 feet, has been purchased to date. The right of way has been located in such manner that in addition to the pole line provision is made for a double-track railway, should future developments warrant its use for such an enterprise.

With a view to providing manufacturing sites for those who may become purchasers from the company of power for industrial or electrochemical uses, some 530 acres of land have been purchased fronting on the Chippewa River, situate about two miles from the town of Niagara Falls, three miles from the confluence of the Chippewa and Niagara Rivers, and about 3½ miles from the point at which the Chippewa River has entrance into the Welland Canal. These lands have a river frontage of over 1½ miles. The purchase price averaged about $70,000 per acre. It is stated that the wisdom of this early purchase is evidenced by the fact that similar lands in the vicinity are now held at a great advance over this figure, caused no doubt by activity due to the development at Niagara Falls now under way.

Installment payments on the company's bonds have been promptly met and receipts have, up to the present, been in advance of expenditures. The cash balance at the credit of the company, in the hands of the National Trust Company, trustees for the bondholders, amounts at present to about $1,000,000. As all the works of the company are being pressed forward to completion simultaneously, progress payments will be required more rapidly in the future, but calls have been so arranged that ample funds will be available to meet all expenditures as the work progresses.

Mr. F. S. Pearson, consulting engineer to the company, gives a report of progress on the construction of your power plant at Niagara Falls.

At the time this work was commenced it was recognized by all those conversant with the plans that the greatest difficulties the company would have to encounter would be in the installation of the cofferdam and the commencement of the work on the main tail-race tunnels. It was considered by many that it would be impossible to carry out the work as outlined on the original plans. Both of these serious problems have been solved in a very satisfactory manner and without serious expense or delay.

It was assumed in the original estimates that the depth of the water would be about 8 ft. as a maximum on the line of the cofferdam, and in view of the fact that this dam was to be located in the midst of the rapids of the Niagara River it was expected that it would be a difficult operation to build a structure that would withstand the excessively rapid current. As the work on the cofferdam proceeded and it became possible to ascertain the depth of the river, it was found that there was 26 ft. of water, but even with this extraordinary depth and the rapid current, the work on the dam has proceeded continuously and at a rapid rate when the difficulties of construction are considered. The most serious part of this work is now completed and there remains only a short spur to connect with the shore in shallow and still water. The dam as constructed is thoroughly stable and secure, as one cannot feel a tremor in any portion of the work and it is evident that the dam is well designed for the purpose intended.

A long section of this dam was constructed over a portion of the river bed covered with very large boulders, on which it was necessary to place the cofferdam, fitted to the boulders as well as was possible under the conditions. Naturally a cofferdam built on such a sub-stratum would show great leakage, and it will require considerable work and time to stop the flow of water under the dam. An inspection of the work at the present time shows that very little water is leaking under the dam, even between these boulders, and there is no reason why the greater portion of these leaks should not be stopped. At the present time the amount of water coming through under the dam is not sufficient to seriously interfere with the construction of the work, as it could be handled by flumes and canals, if necessary. The larger portion of these leaks, however, will be stopped in the next few months, and before the forebay construction is commenced. It can be safely stated that this cofferdam represents as great an undertaking in this line of work as has probably ever been designed or constructed.

The plan for the tail-race tunnel requires a portal under the falls. There have been various theories regarding the condition under the falls, as there are, at times, noticeable explosions, apparently due to compressed air, and it was confidently predicted by engineers conversant with Niagara Falls and the work thereabout that it would be impossible to open a tunnel portal at the point selected on the plan. In order to reach the line of the main tunnel a subsidiary tunnel of about 650 ft. in length was required, and to ascertain the conditions under the falls, as well as to provide for dumping the debris of excavation, an opening was planned about midway of this tunnel. It was anticipated that some trouble might be caused by the water when this opening was made, and the anticipations were more than borne out by the facts, as long before an opening was effected the subsidiary tunnel was flooded with water, which leaked through cracks at the face of the cliff. For several weeks the contractor had a great deal of trouble in overcoming this difficulty, but finally, after persistent and very creditable work, an opening was effected, which has completely drained the tunnel, and also proven that it is perfectly feasible to place the terminal of the main tail-race tunnel at any point desired.

The character of the rock encountered in the subsidiary tunnel is a solid shale, thoroughly tight, and there is not water enough in the tunnel to supply the air drills. In most places the rock is absolutely dry. This is an indication that there will be no trouble in driving the main tail-race tunnel, especially in view of the fact that there is now an opening from the subsidiary tunnel which would drain any volume of water which might come in through a fissure in the rock.

With this opening under the falls assured, and the cofferdam practically completed, the two greatest difficulties in connection with this work have been surmounted. The progress of the subsidiary tunnel (something like 14 ft. per day) is an indication of the progress the contractor should make on the main tunnel. The contractor for the wheel pit is erecting a large and efficient plant for the construction of this pit, and it is evident that he proposes to push this work in every possible way.

On account of the magnitude of the installation and the immense volume of water required for its operation under maximum conditions of load, there has been a question in the minds of the engineers as to the volume of water readily available for the work. This question arose from the assumption that the maximum depth of the water in front of the forebay was only about 8 ft. Plans were under consideration contemplating the excavation of a deep channel in the river beyond the cofferdam limits to provide for a sufficient volume of water. Now that the cofferdam is installed, and the great depth of 26 ft. of water has been found, all questions regarding the supply of water have been set at rest, as it is evident that the amount of water available is several times in excess of that required. While the great depth of the channel has made the construction of the cofferdam much more expensive, it avoids a large expenditure in excavation and absolutely assures the company as regards its water supply, thus compensating for the greater cost.

The plans for the work in general are being completed and contracts have already been placed for the wheel pit, tail-race tunnel and generators. The plans and specifications for the water wheels and iron work about the power station and pole line will soon be ready, so that the contracts for these can be placed within a short time.

The location of this plant is very advantageous and when completed it will be equal in all respects to any that have been proposed or constructed at Niagara Falls. On account of its advantageous location the cost per horse-power will be exceptionally low. With a transmission line to Toronto of capacity sufficient to deliver 30,000 hp, the total cost per delivered horse-power at Toronto will be as low, if not lower, than that for any other plant of a similar nature that has been constructed. The company should also build up a large business in the vicinity of Niagara Falls and along its transmission line, and with the low initial cost the financial success of the company seems assured, as on account of the low cost of its power it should be in a position at all times to meet competition with other concerns and at prices which will realize a good net income.

Mr. W. T. Jennings, chief engineer of right of way, reports that the total distance between the generating station and Toronto is 75½ miles. The location has been selected with a view to the utilization of the right of way lands not only for electric power transmission lines, but for railway purposes, and in this respect it may be noted that the country traversed does not present serious engineering difficulties. Considering the advantages which may thus be obtained for very rapid rail transit, by electric power, between the Niagara River frontier and Toronto, the small additional distance over air lines between fixed points is inappreciable from an electrical transmission point of view, while for the railway of the future, with a train service rated at 100 miles per hour or more, it is obvious that the best alignment and gradients the country can economically afford are necessary.

A private right of way has been largely secured through the districts traversed, on a minimum basis of 80 ft. in width (with enlargements where necessary), to provide for pole transmission lines and for a double-track railway, while where forest land is passed through the right to cut down trees, etc., has been secured for such extra distances as may be advisable to insure freedom from accident, interruption to electric transmission or to train service. Tenders for fencing the entire right of way have been invited.

Electrical Engineering at Union University

During the winter term of 1904, non-students of Union University are admitted as special students in the following courses of lectures given by or under the auspices of the Department of Electrical Engineering: Post-graduate lectures in electrical engineering, by Chas. P. Steinmetz, professor of electrical engineering; general lectures in electrical engineering, by specialists of the General Electric Company and Dr. Steinmetz; engineering mathematics, by Dr. C. P. Steinmetz; electrochemistry, by C. A. Ernst, Ph.D., assistant director of Electrochemical Research Laboratory of the General Electric Company.

An indication of the excellent work being done at Union is given by the following list of lectures by specialists delivered during the fall term: "Introductory," by C. P. Steinmetz; "Magnetism and Induced Electricity," by R. Neil Williams; "Historical Development," by W. S. Andrews; "Direct-Current Machine Action and Application," by H. F. T. Erben; "Direct-Current Machine Calculation and Design," by W. F. Dawson; "Boosters and Variable-Speed Motors," by H. Bickerstaff; "Electrical Calculation of Alternating-Current Generators and Synchronous Motors," by W. J. Foster; "Electrical Calculation of Induction Motors," by A. E. Averett; "Mechanical Design of Generators and Synchronous Motors," by H. G. Reist; "Mechanical Design of Induction Motors," by H. G. Reist; "General Transformer, Boosters, Frequency Converters, etc.", by C. P. Steinmetz; "Alternating-Current Transformer," by W. S. Moody; "Potential Regulators," by E. F. Gehrkens; "Constant-Current Transformers," by M. O. Troy; "Reactors," by J. J. Frank; "Technical German," by R. Neil Williams.

New Telephone Patents.

THE MERCURY VAPOR COLUMN AS A TELEPHONE REPEATER.

Probably almost every electrical man is aware of the multitudinous attempts to solve the problem of the telephone repeater and many will recall the Glidden offer of several years ago of one million dollars for a practical apparatus of this type. The earlier suggested repeaters were all of the same kind, being a mechanical combination of telephone and microphone, with either the same or interconnected diaphragms. Such instruments appear all right in principle and in the laboratory they will repeat with more or less success. When, however, the current undulations to be repeated are received over a reasonably long line, approaching the requirements of practice, the received energy is so small, having been dissipated and attenuated from many causes, that its value on the far side of the repeater is almost always less than were the repeater entirely removed from the circuit. This result may be traced to the large mass of microphone parts which must be set into instantaneous motion, coupled with the fact that any sluggishness in their response means almost an entire loss of clearness.

The first step in the right direction and a very promising one was made some few years since in the repeater of Mr. Erdman, which abandoned any solid connection between the receiving and transmitting parts, substituting therefor a pneumatic connection. In brief, the receiving magnet was made to control the outlet of a

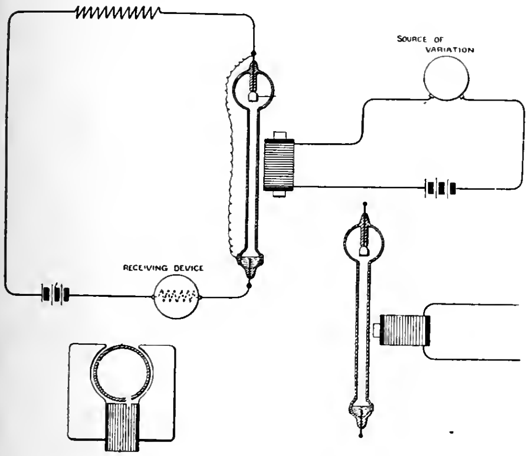


FIG. 1.—HEWITT VAPOR TUBE TELEPHONE REPEATER.

fine tube through which air was flowing at high velocity supplied from a receiver. Near the valve end the tube communicated with a chamber closed by a diaphragm which was connected to the microphone. By carefully balancing the valve of the receiving part and properly designing it, a very small received energy could be made to produce an enormous effect upon the repeating microphone; but this speed of response was too low and this repeater failed, because it muffled the speech. It therefore becomes apparent that some electrical or equally instantaneous means of associating the receiving and transmitter circuits must be found and this an association by which the energy of transmission is increased if a successful repeater is to be devised. Such means form the subject of a patent granted to Peter Cooper Hewitt and noticed briefly last week. According to the specifications, a mercury vapor column which seems to be lending itself to so many useful ends, is found to be very sensitive to a magnetic flux intersecting it, any variation in such flux causing its apparent resistance to change considerably. Now, it may be readily understood that if such a column can be made to maintain a constant resistance when supplied from a constant source of potential, then if it be placed in series with a telephone, no sound will be heard. Let, however, a receiver magnet, through the coils of which an undulatory voice current is flowing, be brought up to the column, and there will at once occur a disturbance in the first telephone due to direct resistance variations of the column. The patent drawings referred to in describing this combination are given in Fig. 1, which shows three possible arrangements of the receiving magnet; the first with the axes of the core and vapor tubes parallel; the second, with these perpendicular, and the third with the body of the vapor tube completely filling the interpolar space, probably the most efficient arrangement. Pactical trial only can probe whether or not this apparatus solves the troublesome problem of repeating on long lines; but, nevertheless, the possibility of a solution is made more evident thereby.

A NEW RECEIVER.

Now that the principles of good receiver design are quite generally known, very few radical departures are to be looked for, such improvements as are made being chiefly along the line of improvements in detail construction to slightly facilitate manufacture or repair. Such improvements are those described in a patent for a receiver just granted to Messrs. S. Sands and C. Cadden, of Cleveland, Ohio, and assigned to the Williams-Abbot Company. The novelty lies in two features. The first is the device for absorbing the mechanical stresses between the receiver and its cord. This is a stirrup attached to the magnet to which the cord braiding may be secured. The second is the provision of a threaded rubber annulus between the cap piece and casing proper. This annulus screws down upon the diaphragm, its external threads engaging threads upon the inside of the flange of the diaphragm cap of the casing proper. The cap is then mounted by engaging with threads upon the internal surface of the annulus.

DOUBLE-DIAPHRAGM TRANSMITTER.

Mr. E. B. Fahnestock, of New York City, has now made farther developments of the double-diaphragm transmitter, the details of the construction of this novel instrument being given in a patent recently issued. Probably a sectional view will be of best service for showing the arrangement of its parts, such as that given in Fig 2. This section is taken in a plane parallel to that of the mouthpiece. The outer cross-hatched portion is the casing into which the transmitter slides. This is so shaped as to form a shallow sound chamber for each of the two diaphragms. The part marked *C* is an internally-flanged ring, which serves as the foundation upon which the microphonic button is built. Secured to this on either side of the flange are the auxiliary diaphragm of mica, *N N*, which are pierced at the middle by the studs of the two metal-mounted carbon electrodes, *O*. Secured to the outer ends of these studs between a nut and spacing blocks are the diaphragm proper, *K K*. These are free at their peripheries, but are placed in recesses designed to prevent the direct access of the sound waves to the rear of them, a condition which the inventor states is conducive to clearness.

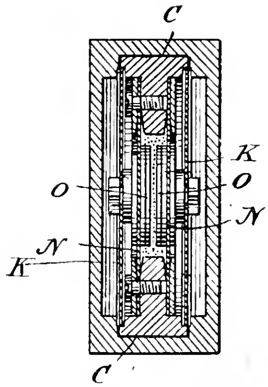

FIG. 2.—FAHNESTOCK TRANSMITTER.

CALL APPARATUS.

One would scarcely think that a telephone switch hook could do service as an automatic telegraphic sender, but nevertheless such a function has been assigned to it in an invention of J. D. Peachey, of East Orange, N. J. This invention provides that the starting of any call by a subscriber, denoted by his removing his receiver from the hook, will be followed at once by the registration by automatic telegraphic means of his number, in dot-and-dash code, upon a Morse register. To accomplish this signal the switch hook is given a long throw and moves under the influence of a heavy spring, the speed being controlled by a dash-pot. In its upward motion a contact piece attached to the hook trails over a series of properly spaced contacts through which the code signal is sent in. On the downward motion no contacts are made, as a deflecting spring throws the moving contact out of position. This particular type of signal would at first thought seem to be of no value; but it is probably designed to co-operate with its inventor's telephone fire alarm scheme, which has been already described in these columns.

PLUG EJECTING JACK.

A switchboard jack designed to automatically eject a plug inserted in it upon the sending in of a clearing-out signal has been patented by R. G. Dunfee, of Fostoria, Ohio. The ejection of the plug is accomplished by a spring which becomes compressed by its insertion, being latched until the current from the ring-off releases its trigger through the agency of the clearing-out coil. The apparatus is probably of far greater value in theory than in practice.

SELECTIVE SIGNAL SYSTEM.

Another step-by-step selective signalling system has appeared, this time in a patent granted to G. Babcock, of Chicago, and assigned to the Stromberg-Carlson Company. This system has some features not usually included in such systems, the most notable of which is an indicator to show the central office operator on disconnection whether or not she has restored the line to normal. Unfortunately, this signal is associated with the connecting cords and not with the abnormal line, and the operator in order to correct any indicated error, must remember which line the particular cord in question was last used with. In some cases the locating of the desired line would be very easy, but where the operator's load was heavy, the very condition conducive to the failure to restore lines, the task of remembering which line was forgotten would be a most difficult one.

American Lighting Development in Venezuela.

Some interesting contracts have just been placed here for various lighting equipments for Venezuela. A number of others have been decided upon and several orders are expected to be closed shortly for more American machinery to be installed in hydraulic and steam power plants in the same South American country.

Carlos G. Palacios, the chief engineer of the electrical end of the Caracas Gas & Electric Light Company, is now in New York on behalf of his company, and also for the Electric Light Company, of La Guayra, both of which concerns will be furnished with considerable American apparatus. Mr. Palacios was the introducer of American electrical machinery into Venezuela, where he has installed the majority of the leading plants—both water and steam power. Some twenty years ago he was connected with the old United States Electric Light Company, of Newark, N. J. The Caracas Company at present draws the bulk of its power—800 hp—from a 2,000-hp hydraulic plant, which is located at El Juaire, about 12 miles distant from the Venezuelan capital. In the city it operates a steam plant capable of developing 500 hp, and equipped with McIntosh-Seymour engines, General Electric generators, and Babcock & Wilcox boilers. This steam plant is to be considerably enlarged and an outfit of 1,000-hp capacity will be put in. Crossley gas engines—four of 250 hp each—will be employed to operate Stanley alternating-current generators of 200-kw capacity each. The lighting plant to be installed at La Guayra—the port of Caracas—will have an initial capacity of 3,000 incandescent and 250 arc lamps. The power house equipment will comprise a 14-in. x 36-in. Hamilton Corliss engine, direct-connected to an 80-kw generator of Stanley manufacture. The boiler will be of Robb-Mumford type, 125 hp. It is anticipated that this plant will be doubled in capacity within six months.

Cuidad Bolivar, an important commercial city of some 15,000 inhabitants, located in the extreme end of Venezuela, on the Orinoco River, is to have an up-to-date American lighting and power plant, whose capacity in the first instance will be 800 hp. Mr. Palacios will act in an advisory capacity to the promoters of the new enterprise, who are wholly Venezuelans. Power will be generated by steam.

Projects are also under way to utilize two important water powers in North Venezuela. In the vicinity of Macuto a town of some 3,000 population, there is located a water fall no less than 2,000 ft. high and calculated to be able to develop 5,000 hp. At Juan Diaz about the same head and capacity are available. It is also contemplated to take advantage of a large water power named the Mamo Falls, capable of developing more power than either of the other two, but with less head.

The lighting plant at Valencia, which is a steam one of 300 hp, having a McIntosh-Seymour engine and a generator of General Electric manufacture, is to be nearly doubled in capacity. At Maracaibo the lighting plant, whose capacity is 1,200 hp, is to be extended. The present equipment comprises McIntosh-Seymour engines, Root boilers and General Electric generators. The water power plant which lights Merida is to be doubled in capacity. The existing machinery develops 400 hp. The water wheels are of Pelton built, direct-connected to Stanley generators. At Tachira the 300-hp hydraulic plant—Pelton wheels and Stanley generators—is to have 500 hp additional equipment.

CURRENT NEWS AND NOTES.

NEW YORK ELECTRICAL SOCIETY.—The 241st meeting of the New York Electrical Society will be held at the American Institute, 19 West Forty-fourth Street, at 8 P. M., February 17. Mr. Ralph D. Mershon will lecture on "The Gas Engine for Central Station Service."

RADIOACTIVE DINNER.—The Technology Club, which is the New York Alumni Association of the Massachusetts Institute of Technology, had a "radium" banquet on the night of February 5. President Pritchett, of the Institute, made an address in which he expressed the hope that the day might come when the nation would draw on "Tech." for its administrators and leaders. The feature of the evening was a radium demonstration, the chief item being cocktails of fluorescent liquids rendered radioactive and glowing in the dark when lifted to the lips.

ITALIAN POSTAGE STAMPS.—As to the new Italian postage stamps noted in these columns last week, it is stated that the painter Michetti, who designed the new Italian postage stamps, has devised an ingenious detail for the two-centesimi stamps, which are in honor of Marconi—a telegraph pole from which the wires hang down useless. All the stamps were made at the desire of the King, who had come to the conclusion that Italy's stamps were no better than those of France, England and Germany, and did not reflect honor on a country known as the home of classical art. The other electrical stamp does honor to Volta.

PURIFYING JUICES.—A patent granted to Messrs. Alexander Kollrepp and Alfred Wohl, of Berlin, Germany, refers to some improvements in the electrolytic treatment of sacchariferous solutions of any kind, as juices of beet root, sugar cane or refinery juices. Essentially, the process of the inventors consists in the separation of the alkali by "electrodialysis," or by amalgamation on a mercury cathode, and in the binding of the acids, liberated at the anode, by basic compounds of lead oxide or zinc oxide or hydroxides of thin metals, suspended in the juice. The employment of saccharate of lead for the latter purpose is especially recommended.

CHICAGO INSTITUTE MEETING.—The Chicago branch of the American Institute of Electrical Engineers announces a "Telephone" meeting for February 16, 1904, at the usual time and place, 1741 Monadnock Block, at 8 P. M. This meeting was postponed from February 2, the date first announced. The general subject of the meeting will be the "Automatic Telephone Exchange." Two papers will be read and discussed at that time. The "Economics of the Automatic Telephone Exchange," by F. J. Dommerque, and "Two Methods of Giving Toll Service with Automatic Exchanges," by Charles S. Winston.

GREAT FIRE AT BALTIMORE.—On Sunday, February 7, the city of Baltimore was devastated by a fire which continued burning 48 hours and destroyed property to the estimated value of $150,000,000 to $200,000,000. The fire began in a wholesale dry goods store and is reported to be due to the explosion of gasoline kept in a tank and employed to run an engine. Very few details are obtainable as we go to press, but it would appear that the Western Union, Bell Telephone, Postal Telegraph and United Light & Power and Railway systems have suffered very severely. Some of the plants have been wiped out or wholly destroyed, and there has been an urgent call for new apparatus.

CONSTRUCTION OF PLANTÉ PLATES.—A patent granted on February 2 to Mr. Joseph Bijur, of New York City, who has been active in recent years in developing a new form of storage battery, relates to the mechanical construction of the plates. His battery is of the Planté type, very minutely divided strips, shelves or shreds of lead (afterwards to undergo a process of formation) being autogenously united with lead or lead-antimony supports. His present patent relates to the arrangement of the strips in such a way as to insure that the crowding effect of the layer of active material produced afterwards during formation does not lessen the strength of the plate.

TRAMPS AND TELEPHONES.—One of the many benefits of the use of the telephone in rural districts is the check upon the lawless tramp. In one county in Indiana the tramp nuisance has been largely mitigated by the prompt enlistment of the Sheriff's aid by telephone. Out there it is the belief that where there are telephones tramps cannot abide.

RADIUM IN MONOPOLY.—The *Matin* and other Paris newspapers are loud in demanding that radium remain a specific French article, which all the world shall buy here. "Radium," say the papers, "is a French discovery, and we would be foolish to allow other nations to profit by the genius of our scientific men." At the same time Austria is being savagely attacked "for keeping up the price of the raw material"—in order to protect her Bohemian glass industry.

N. E. L. A. ANNUAL VOLUME.—The National Electric Light Association has just issued its volume of transactions containing the full report of the Chicago convention of 1903. It is a superb record in every way and reflects great credit upon all concerned. It embodies, moreover, a great deal of valuable matter in the shape of papers, discussions, reports, answers to questions, etc. The main part of the volume embracing the report proper runs a length of 538 pages, but there is a huge appendix inclusive of two or three appendices making at least another 300 pages. The members of the Association, if they got nothing else, might well rest satisfied with this evidence of the Association's activity and influence.

NATIONAL ELECTRICAL CONTRACTORS.—The National Electrical Contractors of the United States held their quarterly meeting at the New Willard Hotel in Washington, D. C., on February 1. After the morning session the delegates were entertained at luncheon by the local members of the Association. During the day they visited the White House and were presented to President Roosevelt. Mr. E. McCleary, of Detroit, president of the Association, made a short address, which was responded to by President Roosevelt in a very happy speech. The members expressed themselves as highly pleased with their reception. There was a good attendance at the meeting. The annual meeting will be held at St. Louis on September 13, 14, 15 and 16 next.

HARDENING ALUMINUM.—Since the commercial introduction of aluminum an important problem has been the discovery of means for hardening the material so that it might enter into uses which the softness of the pure metal precludes. It is claimed that a discovery of such a means has recently been made by W. Rubel, of Germany, the process of hardening being a chemical one. The new metal is called "meteorit" and is claimed to retain all the good qualities of pure aluminum and possess important new ones. The specific gravity is practically equal to that of aluminum; the metal is not affected by acids, the atmosphere or sea water; it can be cast like iron, has 8 per cent. greater tensile strength than cast iron, and can be recast without losing its qualities. It can be rolled cold and does not become brittle when hot; it has nearly the conductivity of copper, will keep a high polish, and can be plated. We understand that the American patents for this new metal are now being offered for sale.

TROUBLE IN KOREA.—On January 24 the United States State Department at Washington received official information of an attack by a mob of native Koreans on an electric car because it had killed a Korean. The news came in the following cablegram received from Minister Allen at Seoul: "This morning on the electric railway, which is the property of American citizens, a Korean was accidentally and unavoidably killed. Thereupon a mob of natives attacked and partially destroyed the car. The operators of the car would have been injured had it not been for the presence of mind and action of our guard, and a serious riot would have occurred." Although there have been previous reports of disturbances in Korea, this is the first mob attack made on the property of Americans. The railroad is owned and operated by Americans, H. R. Bostwick, of San Francisco, and H. Collbran being its principal officers. It runs through the heart of Seoul. The United States Legation guard now consists of 100 marines. The reinforcement of this guard has been urged, and could be effected in a week's time by details of marines from the Philippines.

LETTERS TO THE EDITORS.

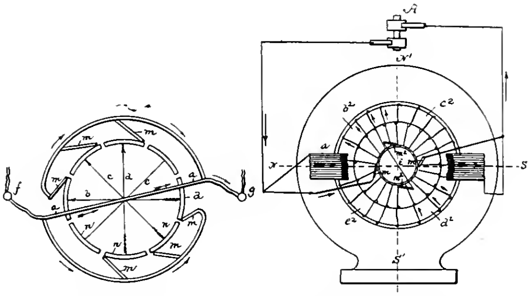
Invention of the Alternating Current Commutating Motor.

To the Editors of Electrical World and Engineer:

SIRS:—I have read with much interest in your issue of January 16 the note in the Digest (page 143) in regard to the controversy between Mr. Latour and Messrs. Eichberg and Winter regarding the priority of invention of the motor in question. The interest aroused in this subject will perhaps justify a suggestion from me as to the solution of the puzzle, "who is the original inventor?"

As there has been much work done in alternating-current commutating motors in the past decade, I had the suspicion that the fundamental principle of compensation applied in different ways in the Latour and Eichberg-Winter motors, was embodied in some other machine before. My suspicions were confirmed by finding United States Patent No. 476,346, filed on November 14, 1888, by Mr. M. J. Wightman and granted in June, 1892, which describes and illustrates fully the actual Latour compensated motor, not only in principle, but in construction.

The drawing and the principal points of this patent are sufficient to demonstrate that the inventor in 1888 was guided to study and



WIGHTMAN ALTERNATING-CURRENT COMMUTATING MOTOR.

propose his motor by the same motive that guided M. Latour in 1902. To quote from the specifications: " . . . . a successful alternating-current motor must have very little self-induction. The difficulty in using an ordinary series or shunt motor for alternating current comes from this cause. . . . . . . An alternating-current motor consisting of a closed circuit armature having opposite commutator brushes maintained in position approximately ninety degrees from the main brushes and connected directly with one another, said main brushes being connected to a source of alternating current, etc. . . . . "

Further comments are unnecessary, but it may be added that for the second time in recent years an old compensated alternating-current motor (or motor provided with means for diminishing the self-induction of the armature) is successfully resuscitated by virtue of the improved construction of electrical machinery. This was the case with the George-Heyland and now with the Wightman-Latour-Winter-Eichberg motors. The conclusion is that a study of the patents records is to be recommended to inventors in place of text-books.

CHICAGO, ILL. VICTOR MARTINETTO.

[The specifications of the Wightman motor refers to the patent of Elihu Thomson of May 17, 1887, on the repulsion motor, and state that, while the principle of the repulsion motor is utilized, "the alternating current in both field magnet coil and armature are both directly derived from an external source of current, which current is led through the two members in such direction that the synchronous alternations will each cause repulsion between them. The source may be of any desired nature—as, for instance, an alternating dynamo or a transformer. In practice, the best results are obtained by connecting the field magnet coil and armature in multiple to the alternating-current wire leading from the source. A simple form of motor embodying the invention would consist of an armature and field magnet such as shown in the [Thomson] patent before referred to, the connections to the open-circuited coils of the armature being made such that as they successively come into circuit with the source they will carry alternating currents from the same, each of which will be in opposite direction to the simultaneously-flowing alternating current in the field magnet coil. . . . The principle of my motor is to cut out of action those portions of the motor which have great self-inducion. This can only be done by utilizing the repulsive effect and throwing away the attraction or using its self-inductive effect to take coils out of circuit." The essential point of the four claims of the patent is, as stated in claim 3, "a commutator by which the armature coils in one-half of the magnetic field or fields are cut out of circuit, the coils in the remaining half being alone used for producing the motive power."—Eds.]

Distribution of Gas Power.

To the Editors of Electrical World and Engineer:

Sirs:—In view of the fact that large gas engines are now practical as prime-movers, the thought suggests itself that gas could be used to distribute power over large areas.

Take, for instance, a large urban railway system, it seems possible that instead of having one or more large central stations delivering high-tension alternating currents to rotary sub-stations, that a large gas plant could be used which could be connected by pipe lines to sub-stations, these sub-stations to contain gas engines running generators feeding the lines as at present.

It seems that a plant of this description would have advantages over the present system, namely, immunity from break-down, to which the present high-voltage distribution systems are liable, since the primary distribution of energy would be made by pipes laid underground. The gas plant would also produce by-products which could be disposed of at a profit, and there would be a saving in fuel costs on account of the higher efficiency of energy transformation in the prime-movers, etc.

St. Louis, Mo. J. D. Edwards, Jr.

[A number of patents have been issued to Mr. George Westinghouse on systems of gas distribution in connection with electrical generation. Among the patents are one or more relating to electric traction work which cover the automatic starting and stopping of gas engine sub-station plants through contacts made by an electric car approaching or receding from the block served by the plant.—Eds.]

DIGEST OF CURRENT ELECTRICAL LITERATURE.

Dynamos, Motors and Transformers.

Tandem Connection of Induction Motors.—Danielson.—An illustrated article on the use of induction motors in rolling mills and in iron works in general. In a large Swedish iron works induction motors are used throughout, most of them being of the ordinary type, so that their speed cannot be easily varied. One motor, however, is used which, without losses in a rheostat, can be operated at the nearly synchronous speeds of 428, 375 and 333 r.p.m. The machine consists of a combination of two motors; the main motor, which is an ordinary 14-pole induction motor, and an auxiliary

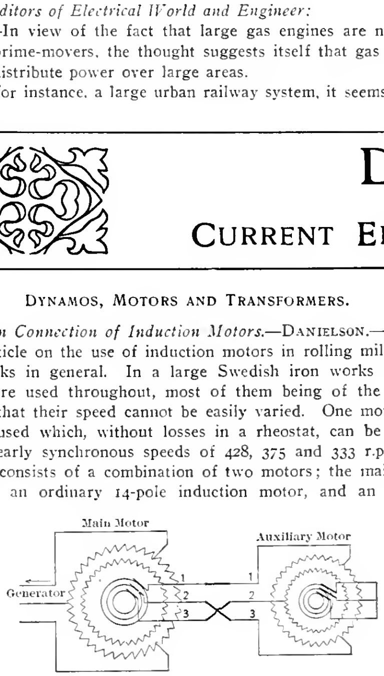


FIG. 1.—TANDEM CONNECTION OF INDUCTION MOTORS.

motor, which can be operated as well as a two-pole or as a four-pole motor. To get a speed of 428 revolutions the main motor is operated alone, while the auxiliary motor is without current. To get 375 revolutions, the auxiliary motor is connected so as to act as a two-pole motor and is connected in tandem with the main motor. To get 333 revolutions, the auxiliary motor is connected so as to act as a four-pole motor and is connected in tandem with the main motor. The power is always 150 hp. At 333, 375 and 428 revolutions and full load the efficiency is 87, 88 and 89 per cent. and the power factor 81, 83 and 92 per cent. It is necessary to design the

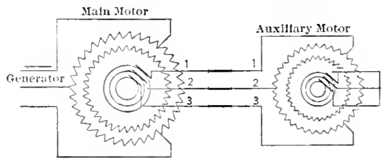

FIG. 2.—TANDEM CONNECTION OF INDUCTION MOTORS.

auxiliary motor so that the leakage is very small and the magnetizing current is also small. In the above motor only the direct tandem connection is used. If one would also apply the so-called differential tandem connection it would be possible to get with the same motor two other speeds, namely 500 and 600 r.p.m. It would only be necessary to provide the rotor of the auxiliary motor with slip rings. The author finally discusses the following three possible tandem connections between a main motor and an auxiliary motor. Fig. 1 shows the direct tandem connection; Fig. 2 shows the differential tandem connection in which the main motor is connected to the supply network, while Fig. 3 shows the differential tandem connection in which the auxiliary motor is connected to the supply network. The arrangement of Fig. 2 gives a better efficiency than that of Fig. 3, but in Fig. 2 the motor does not run up by itself to the desired speed while it does so in Fig. 3.—*Elek. Zeit.*, January 21.

Leakage Factor of Induction Motors.—Breslauer, Zorowski, Hobart, Behrend.—In his book on the induction motor, Behrend had given the following formula for the leakage factor: It equals a constant multiplied by the ratio of the radial depth of the air-gap to the polar pitch. This "constant" varies, however, somewhat for different conditions of design. In a recent paper of Hobart (Electrical World and Engineer, January 25), the variation of this "constant" was discussed in detail and curves were given for the same for completely closed and for wide open slots, with varying

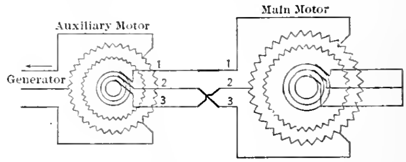

FIG. 3.—TANDEM CONNECTION OF INDUCTION MOTORS.

ratio of the radial depth of air-gap to the polar pitch at air-gap. In connection with this paper of Hobart, which was also published in *Elek. Zeit.*, a discussion of Behrend's formula has been started in the correspondence columns of the latter journal. Breslauer attacks the assumption that by increasing the radial depth of the air-gap, the leakage factor should always become worse. He refers to former researches in which he has shown that if the air-gap is increased, the magnetizing current must correspondingly increase, while the short-circuit current does not remain constant, but also increases to a certain degree. Under certain conditions the increase of the short-circuit current may be even greater than that of the magnetizing current, so that with an increased air-gap the overload capacity and the maximum power factor may be increased. If the rotor is fully removed he has found that the short-circuit current generally increases by 30 or 40 per cent. He thinks that Behrend's formula should be used with caution, since it supposes that the short-circuit current remains constant with varying air-gap.—*Elek. Zeit.*, November 26. Zorowski agrees with Hobart that the use of too great a rotor diameter is a mistake, but he denies that the reason is that the power factor would be too small; he thinks the reason is based on considerations of economical design. He claims that Hobart exaggerates the influence of the "free" winding on the leakage, and that the poor power factor (0.83) in Hobart's example is due to bad design. For the predetermination of the leakage factor of induction motors he has found Niethammer's method to be the most exact one, in which the magnetic reluctances of all leakage fields are calculated.—*Elek. Zeit.*, December 3. Hobart replies to Zorowski that the motor given by him as example was not as an example to show; that the diameter was much too large and the length much too small, and that a better power factor would have been produced if the dimensions had been correspondingly changed. He thinks that Zorowski and many other designers underestimate the influence of the "free" length upon the leakage.—*Elek. Zeit.*, January 7. Behrend replies to Breslauer that the latter's experiments (which showed that the magnetizing current increased with increasing air-gap) were made with a motor with closed slots and the air-gap was increased, the iron cross-section in the bridges at the sides of the slots was also decreased and the magnetic reluctance of the field of self-induction was increased. It is self-evident that under such conditions the short-circuit current must become greater. But this is a case which is of no practical importance and which is not intended to be covered by his formula. What is of importance is to know how the short-circuit current varies, if the air-gap is changed, without changing the form of the slots and the thickness of the bridges. His formula was based on experiments with rotors of different diameter, but of the usual form of slots. He has now repeated these tests and has corroborated his old results. He has found that Breslauer is wrong in stating that the short-circuit current is greater with the rotor removed than under normal conditions. He has tested all new types of induction motors designed by him and has found that the stator consumes about the same short-circuit current when the rotor is removed or when it is in place. The differences in the current depend much more on the type of winding than on the fact that the rotor may be removed.—*Elek. Zeit.*, January 21.

Single-Phase Motor.—SCHÜLER AND MÜLLER.—Two communications criticising the single-phase motor of Corsepius recently noticed in the Digest. Schüler remarks that the motor is really no single-phase motor, but a two-phase motor in combination with a single-phase-two-phase converter. It has long been known that an ordinary single-phase motor can be used for changing single-phase into polyphase current. While Corsepius' motor is theoretically interesting, it has too great practical disadvantages, being expensive and having a poor power factor. From the figures given by Corsepius his motor has a power factor of 0.56 at full load, which may, however, be partly due to the imperfect design of the experimental motor. There is at present a practical need for single-phase motors with a great starting torque and also for single-phase motors which start with a slight torque and a very small starting current (larger motors in connection with lighting systems). For both applications he believes the commutator motors to be very suitable. He does not think that Corsepius' motor can compete with the latter. It is now possible to build alternating-current commutator motors which, with regard to sparkless running of the brushes, can be compared with good direct-current motors. Müller also remarks that during starting period the auxiliary motor of Corsepius is nothing but a converter which supplies two-phase current to the main motor, so that the latter starts in the same way as a normal two-phase motor. The auxiliary motor must furnish during this time the whole energy for the second phase and can, therefore, not be too small if it shall not be heated too much or fall out of stop.—*Elek. Zeit.*, January 21.

REFERENCES.

Non-Synchronous Single-Phase Motor.—EICHBERG.—A communication, in reply to Görges, on the theory of the single-phase motor, and especially on the "cross field." This has here another function than in the direct-current motor, in which the cross field may be diminished without diminishing the action of the motor. On the other hand, in the single-phase motor the cross field which is produced is the real magnetic field, which, together with the ampere windings of the stator winding, produces the torque.—*Elek. Zeit.*, January 14.

Diagram of the Induction Motor.—HEYLAND.—Some theoretical and historical notes on the development of the circular diagram of the induction motor. He says that what is now called the Ossana diagram was already given by him in his first publication on this subject.—*Elek. Zeit.*, January 21.

LIGHTS AND LIGHTING.

Incandescent Lamp of High Economy.—BRESLAUER.—In a paper read before the Vienna Electrical Society he exhibited a new incandescent lamp patented by Just, which is claimed to represent an exceedingly important progress in electric lighting, since the lamp is claimed to use only half the current per candle than the carbon filament lamp. Such lamps have been built for 30 candles and 110 volts with a useful life of 250 to 300 hours and a consumption of 1.7 to 2 watts per candle. Two such lamps of 30 candles were exhibited by the speaker. The commercial manufacture of the new lamp, "the filaments of which are treated with an addition of boron nitride," is said to be neither more difficult nor more expensive than that of carbon filament incandescent lamps. To a question whether lamps for 16 candles and 110 volts have been made he replied that the manufacturers have not yet succeeded in doing so, but they hope to be able to build this normal type in the near future. The manufacture of 16-candle lamps for voltages up to 50 volts is, however, already possible.—*Elek. Zeit.*, January 21.

Osmium Lamp.—LOMBARDI.—An account of an investigation in which he measured the temperature of the filament of the osmium lamp by the same method which Weber had applied for the investigation of the carbon incandescent lamp. He first gives a summary of Weber's theory. Weber had found that the temperatures corresponding to the normal brightness of a great many different carbon filament lamps were all in the interval between an absolute temperature of 1565° and 1586°. Only for lamps with very strong brightness, or for lamps with thick filaments, which can be operated without disadvantage at higher temperatures and with greater economy, the normal temperature was found about 40° higher. The present author concludes from analogous measurements with the osmium lamp that the temperature of its filament at normal brightness is about 1435° (apparently meaning absolute temperature, which would correspond to 1162° C.), this is about 135° less than the normal temperature of the carbon filaments of ordinary incandescent lamps. To explain that nevertheless the economy of the osmium lamp is much better than that of the carbon filament lamp he takes recourse to Weber's theory, according to which the economy of an incandescent lamp depends upon two independent quantities, namely, the absolute temperature and a characteristic value, called by him the "illuminating capacity" (Leuchtvermögen). If operated at an equal temperature between 1400° and 1500° absolute temperature, he concludes that the osmium lamp would have an economy 9.1 to 12.5 times better than that of the carbon filament lamp. He considers his measurements with the osmium lamp to be an excellent confirmation of Weber's theory. The main result of practical importance is that the considerable improvement of economy, observed with the osmium lamp, is not due to an increase of temperature, but exclusively to the considerable difference between the "illuminating capacity" of osmium and carbon. It is, therefore, not impossible that other substances which are much cheaper and have a high melting point and are more rigid at high temperature can be used for the manufacture of incandescent lamps.—*Elek. Zeit.*, January 21.

Incandescent Gas Light and Electric Arc Light.—A note stating that an official report of Seggel and Eversbusch concerning the best lighting system for the Bavarian public schools had been in favor of incandescent gas light. To counteract this the Schuckert Company had presented another report by Lehmann-Richter, giving the results of comparative tests with two arc lamps or 14 gas incandescent lamps in a school room. The illumination was good in both cases and sufficiently uniform. The electric light did not deteriorate the air nor increase the temperature considerably. With gas incandescent light the temperature at the height of the pupils' eyes was increased in three hours about six degrees, while the carbonic acid contents of the air was increased five times. This is thought to be more than permissible for sanitary reasons. The cost of operation of the Welsbach lights is smaller than that of the arc light in the beginning, but after a short use the cost of operation of the Welsbach mantles becomes as high as that of the arc light.—*Elek. Zeit.*, January 21.

REFERENCES.

Electric Arc.—SCHULZE.—An account of an experimental investigation on the electric arc between metal electrodes or between a metal and a carbon electrode, and especially on the voltage loss in the arc. To explain his results the author brings forward the hypothesis that such quantities of electricity, as used in lighting currents, can go over from a solid body or from a liquid into a gas only in connection with molecules of the solid body or the liquid; that is, only under the condition that the latter body evaporates.—*Ann. d. Phys.*, Vol. 12, 1903, page 828; abstracted in *Elek. Zeit.*, January 21.

Electric Arc.—STARK.—An account of an investigation in which the author endeavors to elaborate the view that in the electric arc positive and negative ions are the carriers of the electric current. One of his principal assumptions is that in the arc light the "negative electron ions are obtained from the cathode itself, not by ionization, but by electrification." The cause of the emanation is the high temperature of the cathode.—*Ann. d. Phys.*, Vol. 12, 1903, page 673; abstracted in *Elek. Zeit.*, January 21.

POWER.

Thury High-Tension, Direct-Current Power Transmission.—In a description in the Lond. *Electrician* of the power transmission between St. Maurice and Lausanne, the opinion had been expressed that a transmission on the series direct-current system is "hopelessly out of date." The Compagnie de l'Industrie Electrique, which had installed this transmission, contradicts vigorously and refers to the experience at Lausanne (where the very peculiar combination of the Thury system for transmission to the city with three-phase transmission within the city is used). It is stated that since the day of putting the installation into service, in July, 1902, until now the high-tension, direct-current transmission "has not been interrupted one hour for reasons of failure of the electric plant, while the secondary distribution, which is carried out with alternating currents at a pressure of 3,000 volts only, has had to be stopped several times on account of failures of the transformers or of the line." It appears that the Thury system is considered especially suitable for large power transmissions and for long distances.—Lond. *Elec.*, January 22.

Power in Mines.—CAMERON.—An illustrated article on the use of electric power in an oil mine in the Lothian district in Scotland. Three-phase induction motors are used for breaking, hauling, pumping, etc. Their great reliability is emphasized and it is mentioned that a 30-hp induction motor is employed to drive gas-exhausters in the distillation plant, and has been running for six months without a single stoppage, and for most of this time, without stand-by power. Any stoppage for a moment of these exhaust fans would be extremely serious, since the gases would rush back into the retorts and cause an explosion. For traction two locomotives are used, supplied with 500 volts direct current from a trolley wire. The results of the introduction of electric power have been a great reduction in coal consumption, as compared with many mines in the neighborhood: economy in labor, since the induction motors practically do not need attention; greater elasticity, cleanliness and convenience.—Lond. *Elec. Rev.*, January 8.

Drilling and Riveting Machinery.—PERKINS.—A fully illustrated article on portable electric drilling and riveting machines for use in shipyards. He distinguishes the following three types: Those operated by electric motors without electromagnetic devices for holding drills to plates; those with such electromagnetic devices, and electro-pneumatic drills and riveters which use electricity only to hold the machine against the plate to be riveted.—*Cassier's Mag.*, February.

Water Power Plant in Greece.—GUARINI.—An illustrated article on the first hydroelectric plant of Greece, at the foot of the mountain of the Muses. There are two 130-kw, 5,000-volt, three-phase alternators mainly for use in connection with a pumping station.—*Eng. Mag.*, February.

TRACTION.

Surface Contact System.—A description of the "G. B." surface contact system, which is being used on an experimental line in England. The bare conductor, consisting of stranded galvanized iron cable, is drawn through plain stoneware pipes, and is suspended at convenient intervals by vitrified clay insulators. Every 7 ft. 6 in., corresponding to the distance between studs, a short vertical earthenware tube is cemented to the main horizontal pipe, as shown in Fig. 4. Into this vertical portion of the pipe system the laminated stalk of the stud is let, the upper portion of the intervening space between it and the tube being subsequently filled up with bitumen, a packing of jute yarn preventing this material from falling through.

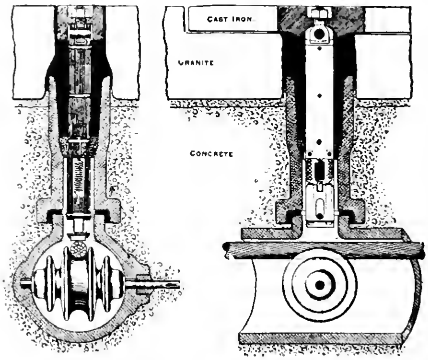

FIG. 4.—SECTIONS OF STUD.

A loosely fitting contact plunger, consisting of a laminated body and a carbon contact piece, slides in the brass-lined fork of the stalk. It is electrically connected to the stalk by flexible copper conductors and is held up from the cable against the force of gravity by an insulated phosphor-bronze spring. The stalk is connected to the cast-iron stud by a somewhat flexible joint, but this does not prevent it from making good electrical and magnetic contact. A recessed granite block receives the stud, which is level with the track. Each car is provided with a magnet rigidly suspended beneath the car and a battery of accumulators which serves for starting only, being charged during ordinary running. One pole of the magnet is in the form of two parallel iron bars, suspended at a distance of about two inches above the center of the track. Between these two bars are a number of iron tongues, suspended by

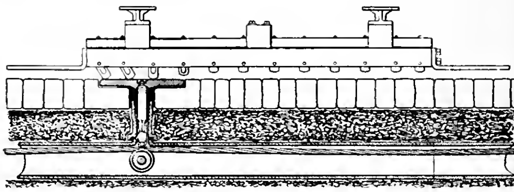

FIG. 5.—CURRENT-COLLECTING DEVICE.

springs, but free to move a considerable distance up and down. These are all connected at their lower ends by one flat chain belt, about 5/8 in. wide, which is kept parallel to the track at a distance of approximately 3/8 in. by the springs and tongues referred to. In order to have a continuous supply of current, the belt is made longer than the distance between any two studs. As the car comes over each stud, both the flexible chain belt and the sliding plunger are attracted downwards, and the former, on coming in contact with the stud, completes the electric circuit. In case the stud should remain alive after the chain belt has passed it, the supply is interrupted by means of chains fixed to the end of the car and trailing on the track, coming in contact with the live stud and causing a maximum cut-out on the car to operate.—Lond. *Elec.*, January 8.

Electric Traction on Trunk Railroads.—VANDEVILLE.—An article the greatest part of which deals with a comparison between the following two Italian electric railways: The Lecco-Sondrio-Colico & Chiavenna road (105.4 km, three-phase transmission, at 20,000 volts to transformers along the line, which reduce the voltage to 3,000, at which pressure three-phase motors on the trains are supplied), and the Milan-Porte Ceresio road (73.02 km. three-phase transmission at 12,000 volts to converter sub-stations, the trains being supplied with 650-volt, direct-current from a third rail). Both railways are in commercial operation. The author concludes that the only advantage of alternating-current traction is the use of high voltage for long-distance lines. However, a direct-current system can also be used over a comparatively long line, if a series system is used. The motors may easily be constructed for 1,000 volts, and by using four motors on a car, couple in pairs of two in series, a voltage of 2,000 may be used on the line. He, therefore, thinks that the superiority of the alternating current begins only when a voltage of 3,000 to 10,000 is to be used.—*L'Eclairage Elec.*, January 23.

REFERENCE.

Electric Traction on Trunk Railways.—BONNIN.—The first part of an article in which the author gives considerations on the future of electric traction on trunk railroads. In order to use the present railway cars, it will be necessary to employ electric locomotives, and the problem resolves itself into two questions: that of the cost and that of the system of current to be employed. The author begins to discuss the second question, but does not reach a decisive result in the present installment.—*La Revue Tech.*, January 10.

INSTALLATIONS, SYSTEMS AND APPLIANCES.

Cologne Station and Double Tariff.—OVERMANN.—A paper read before the Cologne Electrical Society. The city has now two electric stations. The one plant contains four 500-kw machines, the second station four 1,000-kw machines. The ratio of the sold kilowatt-hours to the available kilowatt-hours was 15.5 per cent., 24.5 per cent., in 1900, 1901 and 1902, respectively. It is thus seen that the load factor has only recently been increased, due to a lower rate for electrical energy. Data are given on the financial results during the last seven years, and it is shown that even if only a small profit is made per kilowatt-hour a considerable increase in the sale of electrical energy produces good financial returns in general. There is now used a double tariff, according to the time at which the energy is used. During the time of reduced rate 5 cents is charged per kilowatt-hour for use up to 1,000 kw-hours; for 1,000 to 2,000 kw-hours the first 1,000 kw-hours are charged $50 and every further kilowatt-hour 4.5 cents, etc.; for more than 20,000 kw-hours the first 20,000 kw-hours are charged $690 and every further kilowatt-hour 2½ cents. During the hours of the higher tariff 12½ cents are charged per kw-hour up to 1,000 kw-hours. For 1,000 to 2,000 kw-hours the first 1,000 kw-hours are charged $125 and every further kilowatt-hour 11¼ cents, etc.; for more than 40,000 kw-hours the first 40,000 kw-hours are charged $2,850 and every further kilowatt-hour 3¾ cents. The time of the higher tariff is in January, between 4.30 P.M. and 9 P.M.; in February, 5.30 to 9.00; in March, 6.30 to 9.00; in April, 7.30 to 10.00; in May, 8.00 to 10.00; in August, 7.30 to 10.00; in September, 6.30 to 10.00; in October, 5.30 to 9.00; in November, 4.30 to 9.00; in December, 4.00 to 9.00. At all other times the reduced rate is charged so that during June and July this lower rate is always charged. No difference is made whether the energy is used for lighting or power purposes.—*Elek. Zeit.*, January 21.

Stepney.—An illustrated description of the Stepney Borough Council electricity works, which is worked in conjunction with a refuse

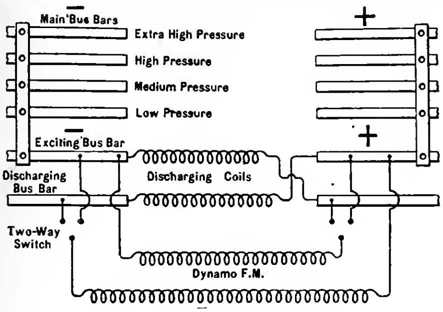

FIG. 6.—DIAGRAM OF CONNECTIONS.

destructor which, however, can furnish only a limited amount of steam. The plant contains four 275-kw and one 500-kw dynamos. The arrangement of the switchboard is interesting and is shown in Fig. 6. The positive and negative panels are each provided with four main bus-bars. By means of short bars at right angles to these, and suitable plugs and sockets, any feeder can be plugged on to any bus-bar. Similarly, separate bus-bars may be employed for separate generators, or they may all be plugged together. This arrangement permits of feeders which supply distant points being raised to a higher potential than those supplying points close to the station. The dynamo and feeder cables are so arranged as never to come into contact. There are two smaller bus-bars below the main bus-bars, the top one supplying the exciting current, and the lower one being called the "discharge bar." Instead of employing a separate coil for each dynamo for damping the rises of potential due to self-induction obtained when breaking the field, only two coils are used for all machines in the station. According to the direction in which the fields are wound, they are connected up as shown in the diagram, and the result is a considerable simplification and reduction in the number of switchboard connections.—Lond. *Elec.*, January 8.

Frankfort Electric Station.—An abstract of the official report of the Frankfort electric works. There are two stations. In the first a new 5,000-hp steam turbine has been installed which has been found to be absolutely reliable. Although built for 2,600 kw, single-phase current it is able to give up to 3,200 kw. The whole station contains four steam dynamos each of 552 kw, four steam dynamos each of 1,033 kw, and one turbo-generator of 3,200 kw. The consumption of fuel per generated kilowatt-hour was 1.63 kg. (3.6 pounds), against 1.72 kg. in the preceding year. There were generated in 1902 15,773,781 kw-hours. The house connections aggregate 16,110 kw, which is equivalent to 322,200 incandescent lamps of 16 candles. The second plant has a capacity of 402 kw direct current and 1,000 kw, three-phase current.—*Elek. Zeit.*, January 7.

Liquid Rheostats.—NIETHAMMER.—Some theoretical considerations on the design of liquid rheostats. There are two types. In the first the liquid in the containing box is constant and the electrodes are movable; in the second the electrodes are stationary and the quantity of liquid is changed. The author gives some numerical data on the resistance of various electrolytes, suitable for this purpose, and then shows theoretically that one should distinguish between liquid rheostats used only for a short time (for instance, for starting) and those which are in circuit for a longer period. For the former one should endeavor to use a large quantity of liquid with a small surface, which for the latter case a small quantity of liquid with a large surface is preferable. In the latter case the surface should be corrugated or a containing vessel of ring form should be used.—*Zeit. f. Elek.* (Vienna), January 17.

ELECTRO-CHEMISTRY AND BATTERIES.

Permanent Magnets.—WEICHSEL AND HIECKE.—Two communications referring to a recent discussion by Emde whether a permanent magnet is to be considered as the seat of a certain number of lines of force or of a certain m.m.f. In opposition to Emde, Weichsel arrives at the result that the m.m.f. of a permanent steel magnet is to be considered constant. He gives some theoretical considerations to prove that we must assume that when the magnetic reluctance is increased, a permanent magnet gives off energy in some form, perhaps heat. Hiecke criticises some theoretical suppositions of Emde and Busch. He agrees with the latter that in producing a permanent magnet, the magnetism becomes the stronger, the smaller the reluctance in the air-gap in the magnetic circuit, other things being equal. He has found that permanent magnets for a registering instrument when magnetized with the pole shoes (which considerably decrease the magnetic reluctance) obtained a much higher magnetism than when magnetized without these pole shoes. Concerning Emde's fundamental question mentioned above, he claims that practically constant properties can be found in permanent magnets only if they are subjected to no or very small external magnetic influences. In this case the number and direction of the lines of force and the m.m.f. are constant. If, however, a strongly magnetized body is approached to the magnet, the number and direction of the lines of force is changed. This change will be instantaneous if the movements of the molecules inside the magnet can go on within the elasticity limit. If, however, a further external impetus is necessary, in form of a very strong movement of the molecule or of a long series of preceding changes of positions of other molecules, the changes of the lines of force in the permanent magnet will require time. A well-known example for this phenomena is a gradual increase of the tractive forces of a magnet to the poles of which an armature has been attached.—*Elek. Zeit.*, January 14.

Rotation of Lines of Force.—DUESING.—Hoppe had investigated whether the lines of force of a magnet revolve with it, and has found that they do so, since they show a slight drag in the direction of rotation. The present author has investigated the further question as to whether the lines of force revolve with a rotating armature when the magnets remain fixed, and also found a slight drag in this case. He laid a flat iron ring between the poles of a permanent magnet, covered it with paper and dusted iron filings upon it. With a proper field strength he obtained a slight tracing of the lines of force within the ring, in spite of its shielding action. He then substituted a piece of photographic paper for the ordinary paper, and made the ring revolve about its own axis. The tracing of the lines of force obtained during the rotation was fixed by holding a lighted match over the paper. The tracing showed a distinct but slight inclination of the lines of force both within the ring and outside of it in the direction of rotation. The ring must, therefore, have dragged the lines of force with it to some extent.—*Ann. d. Phys.*, 1903, No. 13; abstracted in Lond. *Elec.*, January 22.

Electro-Chemistry and Batteries.

Soldering Aluminum.—An anonymous communication in which the following composition of a solder for aluminum is given: 10 parts bismuth, 30 parts zinc, 60 parts pure tin. The bismuth and zinc are first melted and the tin is then added; the whole is poured into molds about a foot long and about the size of a pencil. To do the soldering the writer uses a stick of solder, an old nickel aluminum spoke and a blow torch. The pieces to be soldered are held in a vise or any convenient place, the flame is applied from the torch until they are hot enough to melt the solder, when it is applied, then the surface to be soldered is scraped with a file or scraper. The solder is melted on to each piece and worked around with the spoke; the parts are then held together in front of the flame and the torch is removed.—*Am. Mach.*, January 7.

Dielectric Constants of Solvents and Solutions.—Eggers.—An account of an experimental investigation in which he measured the dielectric constants of various hitherto uninvestigated solvents, notably sulphur compounds. It is shown, notably in the case of the nitriles, that the dielectric constant is not an additive property, but depends to a very great degree on the relative chemical structure of the molecule. In cases where several solvents were used with the same solute, the dielectric constants of the mixture did not indicate that the solute exerted a similar influence in each case. This points to the conclusion that the dielectric constant of a solution is not a simple function of either constituent, but is due to an indefinite compound, i. e., a compound acording to variable proportions, resulting from combination of the constituents.—*Jour. Phys. Chem.*, January.

Units, Measurements and Instruments.

Wehnelt Interrupter.—Van Dam.—An article in which he refers to Zehnder's simplified form of the Wehnelt interrupter. The author describes a further simplification. The difficulty of mounting the platinum pencil in such a manner that no liquid can pass it, is overcome by using india rubber instead of ebonite. As long as the current does not exceed 0.6 amp. per sq. mm., good Para rubber is consumed exceedingly slowly. The author has only once renewed the rubber in his apparatus within the last two years. The operation is of extreme simplicity. The brass rod with the soldered-in platinum wire can be placed directly in the glass tube without using an extra brass tube. Hard solder need not be used, since the joint does not come into contact with acid. The concussions are deadened by the rubber in such a manner that there is practically no danger of breakages. The author uses a tube of 8 mm. internal diameter, to one end of which another tube half that width and about 3 cm. long is fused. The brass rod with platinum wire 1 mm. thick is introduced into the glass tube, and a piece of tubing of the best Para rubber and less than 1 mm. in internal diameter is slipped over the projecting platinum wire. It is wetted with water and then pressed into the narrow tubing.—*Ann. d. Phys.*, No. 13, 1903; abstracted in Lond. *Elec.*, January 8.

Measuring the Resistance of Highly Insulated Substances to Perforation.—Walter.—A long reply to some criticisms brought forward against his method which was described in the Digest October 17. He denies that Holitscher (Digest, November 21) is justified in saying that the method depends too much upon the skill of the operator. He considers that the drop of wax used by him is an advantage because the irregularities of the surface of the material which are of such great importance are thus entirely excluded, and what is measured is the "internal" resistance to perforation. The needle electrodes he also considers an advantage, because with the use of plates as proposed by Holitscher the dielectric hysteresis heat is unnecessarily increased, so that thereby the real internal resistance to perforation is clouded by secondary phenomena. In practice, of course, the condition of the surface and the hysteresis heat are of importance, but these two factors ought to be tested by separate methods. He points out that by his method he has found the following three important general results on the internal resistance to perforation. First, glass containing lead has a considerable smaller resistance than ordinary glass. Second, hard rubber has a considerably smaller resistance if inorganic salts are added to it than without the same. Third, a hard rubber material can be made which has about three times the resistance of that of ordinary kinds of this material. Another criticism which had been made was that the resistance to perforation was formerly measured by the alternating-current voltage required for perforation while he measures it by the equivalent spark length of an induction apparatus between needle electrodes in air. He thinks this is the proper way since measurements of the alternating-current voltage do not give uniform results. —*Elek. Zeit.*, January 7.

REFERENCE.

Influence of Wave Form on the Application of the Two-Wattmeter Method.—Dina.—A criticism of a paper of Bloch recently noticed in the Digest. The present writer claims that Bloch's theory is wrong. He has formerly obtained the following results which are valid for any number of harmonics. The true power factor (determined from the power, the voltage and the current) is smaller than the cosine of the angle between the partial voltage and the partial current for the fundamental wave. The power factor determined by the tangent formula may be either greater or smaller than the cosine of the phase difference between the partial voltage and the partial current for the fundamental wave. The tangent formula gives a value of the power factor larger than the true one.—*Elek. Zeit.*, January 14.

Telegraphy, Telephony and Signals.

Telegraphone.—Strecker.—A brief paper read before the Berlin Electrical Society. He exhibited some apparatus of the Danish and German telegraphone companies. As is well known, the telegraphone is a magnetic phonograph; the transmitted telephone currents pass through the winding of the small electromagnet, before the one pole of which a steel wire or a steel ribbon or a steel disc is rapidly moving. The varying magnetizations due to the telephone currents are impressed on the steel wire or disc. If afterwards the same ribbon or disc is passed before another small electromagnet of the same type, which is connected to a telephone, the original speech is reproduced at the telephone. In the exhibited apparatus either steel wire or discs were used. The wire apparatus has the advantage that it gives louder sounds, because it is possible to move the wire much more quickly. An apparatus with a length of wire of 6,000 meters is sufficient for a conversation of 40 minutes. They have used the apparatus successfully for transmission from Strasburg to Berlin and from Frankfort to Berlin. In another form of apparatus the telegraphone is used in connection with the ordinary telephone, for the use of cautious business men. When they have an important conversation they connect the telegraphone with the telephone and have the whole conversation taken down by the former. Another application is for replacing a stenographer; instead of dictating something to the stenographer, one speaks into the microphone and the whole speech is taken down by the telegraphone. The typewriter then takes the telegraphone and takes the dictation from the latter (as is now sometimes done with the phonograph). If the telegraphone speaks too quickly, she pushes a button and the telegraphone not only stops at once, but goes somewhat back and repeats the last words. In the apparatus with a steel disc the latter rotates, while the electromagnet moves slowly in a radial direction towards the center of the disc. The conversation is, therefore, taken down in form of a spiral line. After a conversation has been impressed upon a steel disc, the latter may be sent by mail to the addressee, who can then hear the message by putting the disc in an identical telegraphone. Compared with the written letter, the "telegraphone letter" has the advantage that it reproduces not only the words but also accents, emphasis, etc.—*Elek. Zeit.*, January 7.

Miscellaneous.

Cure of Cancer by Zinc Ions.—Leduc.—A description of a cure of a cancroid growth, which was in the right wing of the patient's nose, and had existed in a constant state of ulceration for five years. He applied to its whole surface a plug of hydrophil cotton impregnated with a one-per-cent. solution of zinc chloride. This was connected with a positive pole of a battery whose negative pole was connected with some part of the body through a large inert electrode. A current of eight milli-amperes was passed for 12 minutes without causing any pain, and boric vaseline was subsequently applied. The crusts detached themselves immediately, and ten days afterwards the ulcer was completely scarred over and of good aspect. Ten weeks afterwards the scar remained perfect, with the exception of a slight sore at the tip of the nose, which was treated similarly.—From *Arch. d'Elec. Med.*, December 15; in Lond. *Elec.*, January 8.

New Books.

Elements of Electromagnetic Theory. By S. J. Burnett, Ph.D. New York: Macmillan Company. 473 pages, 145 illustrations. Price, $3.00.

The object of this book, as stated by the author in his very brief preface, is "to present in systematic and definite form a simple, rigorous and thoroughly modern introduction to the fundamental principles of electromagnetic theory, together with some of the simpler of their more interesting and important non-technical applications." This is a worthy object, but somewhat difficult of attainment. Several writers have attempted to simplify Maxwell and other authorities, but in some instances the simplification has been more difficult to grasp than the original. The union of profound mathematical powers with a faculty for logical and perspicuous writing is rare, and of a value commensurate with its rarety. The author of the present work is happy in many of his demonstrations; they are elaborated without the unnecessary use of mathematical symbols, the stumbling block of lower grade mathematicians, and while carrying conviction by rigorous reasoning, are not unnecessarily prolix. The mode of treatment of some other demonstrations may not be the best possible, but on the whole the book is extremely satisfactory in mathematical method.

In speaking of the "mechanical conception of the electric field," the author wisely remarks that "this conception" . . . "leads to results by no means wholly consistent." On the other hand, in dealing with the theory of the dimensions of units, the author shows a diminished power of resistance to the logical fallacies of the Rückerian philosophy. The remarks about the dimensions of permeability and capacity recall memories of the polemics upon the subject of "qualitative mathematics," published in that journal some years ago.

Mathematical treatises on electricity usually consider Green's theorem early in the book, but the present work omits it altogether. This is not objectionable in a work which, like this one, makes no attempt at exhaustive treatment of the subject, but confines itself to elementary matters. It is much better than to give an unsatisfactory treatment of the theorem, as is sometimes done. Anyone who has read Green's original paper knows that it is more lucid than some of the commentaries on it. There are other books intending to cover the same field, and although this one does not pretend to originality except in the mode of treatment, it has a *raison d'etre.*

The Elasticity and Resistance of the Materials of Engineering. By Wm. H. Burr. New York: John Wiley & Sons. 978 pages. Price, $7.50.

The present edition of this standard work constitutes almost a new book, one-half or more of the entire volume being new matter. The work as a whole is divided into two parts, analytical and technical. The former consists of five chapters treating the general theory of the subject under the following heads:

Theory of elasticity in amorphous solid bodies; hollow cylinders and spheres, and torsion, flexure, resilience, combined stress conditions. In the development of pure theory the standard methods are for the most part followed, though the author's individuality is often present in the discussion of special points. Taken as a whole, these five chapters furnish an excellent treatise on the general theory of the subject, developed to the extent likely to be needful for the purposes of the engineer.

Part II contains the results of theory applied to the problems of actual engineering construction, and contains most of the new matter in the present edition. It consists of fourteen chapters covering the following topics: Tension, compression, long columns, shearing and torsion, bending or flexure, concrete-steel members, flange beams, connections, plate girders, rope and chain cables, working stresses and factors of safety, miscellaneous problems, fatigue of metals, flow of solids. The chapter on "Concrete-Steel Construction" has received especial attention, and the author has endeavored to set forth here the treatment of concrete-steel beams and other members with sufficient fulness to meet the advancing requirements of this rapidly extending field of engineering construction. Throughout this section of the work the treatment is admirable in arrangement, ample in scope, clear in style and with a due admixture of experimental fact and general discussion. The treatment is especially full in the presentation of tabular matter giving the results of great numbers of tests and relating to all manner and form of constructive material. This section of the work is followed by an appendix of four chapters giving a more general and extended development of the theory of elasticity in amorphous solid bodies. It is not expected that the subject matter of this appendix will be of any great value to the general practitioner; nevertheless, every thorough student of the subject will need to be familiar with the generalized and fundamental treatment of the problems which it presents, and it is for such that the treatment of the appendix is intended.

A further appendix contains the tables and technical data furnished by the Cambria Steel Company, and published in their hand book on structural materials. This matter will be found of great practical value in structural practice, and at the same time is intended to add to the value of the work as a text-book for purposes of instruction, by facilitating the giving of extended practical exercises.

As a whole this work in its present amplified form takes a leading place in the world's literature of the subject. The name of its author carries justly the weight of long years of experience as an investigator, a teacher, and a successful practitioner and advisor. The present volume is one such as we might expect from the long distinguished professional career of its author, and as a general treatise on the subject it will long serve as a standard for use in class room and for daily reference on the part of the practical engineer. Both author and publisher are to be congratulated on the appearance of so extended and so thorough a work on a subject of such fundamental importance to the entire field of engineering practice.

Largest Pipe Organ in the World for St. Louis.

One of the most interesting musical and semi-electrical features of the St. Louis Exposition will be the immense pipe organ built by the Los Angeles Art Organ Company, of Los Angeles, Cal., for the Kansas City Convention Hall Company, and which will be the official concert organ at the Festival Musical Hall. It is, we understand, the largest pipe organ in the world, and is certainly the largest aggregation of musical mechanism placed under electrical control. It is 63 ft. long, 30 ft. deep, 50 ft. high. It has 10,059 pipes. The largest metal pipe is 37 ft. 6 in.; weight, 840 pounds; smallest metal pipe, ¾ in., 3/10 in. diameter; weight less than ½ ounce. The largest wood pipe is 22 x 27 in. inside; stock, 2½ in. thick, 32 ft. long; it weighs 1,500 pounds. Over 80,000 ft. of lumber were used in the organ interior; this does not include that used in the construction of the case. It has 130 miles of electric wire, 140 speaking stops, 1,300 magnets, 99 mechanical movements and is capable of producing 17,179,869,183 distinct tonal combinations. It takes 12 large furniture cars to move it and weighs 250,000 pounds.

Fig. 1 herewith shows the organ set up in the factory, without the display pipes; and its relative size can be inferred from the surrounding objects. The instrument will be played from two independent consoles of the most perfect construction and design. The most important console is movable (Fig. 2) and is connected to the organ by an electric cable 150 ft. long. This console contains the

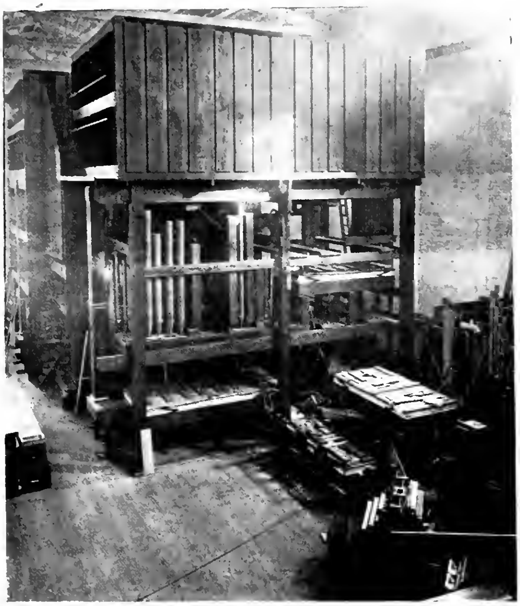

FIG. 1.—ST. LOUIS FAIR PIPE ORGAN.

radiating and concave pedal clavier, the five manual claviers, the 140 draw stop knobs, the five tremulant draws and the 36 coupler draws, the 40 push buttons belonging to the adjustable combination system, and all the foot pedals controlling the expressive powers of the whole organ, etc., etc. This console is for the virtuoso who performs in the usual manner with hands and feet.

The second console is stationary, and is entirely devoted to the builders' double-roll automatic self-playing attachment. Through the agency of the double or twin rolls, the most complicated orchestral scores can be rendered with absolute accuracy, and compositions can be performed which are far beyond the powers of the most accomplished organist. This console resembles that first described, except that it does not possess the manual and pedal claviers, which are not necessary where the double-roll, self-playing attachment appears. Within its arms, so to speak, sits the musician, entirely unembarrassed with the calls of six claviers upon his hands and feet, having at his immediate command the vast tonal forces (represented by 10,000 pipes) of this gigantic organ; his hands simply engaged in manipulating the draw-stop knobs and combination buttons, and his feet controlling the flexible and expressive powers of the instrument. The double rolls do all the rest.

The bellows of the main portion of the organ will be operated by two 10-hp motors, at 220 volts, direct current. The echo organ bellows will be operated by a 1½-hp motor of 220 volts, direct current. The wind-chests, through which the wind from the regulators is distributed to the 140 speaking stops, and the 10,059 pipes, are

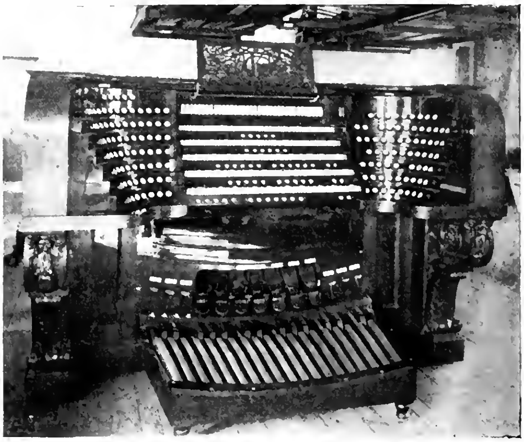

FIG. 2.—CONSOLE OF ST. LOUIS FAIR PIPE ORGAN.

12 ft. long and of widths sufficient to give every rank of pipes planted thereon ample speaking room.

The organ is constructed under the Fleming electropneumatic system, which gives the most satisfactory results. The organ contains 1,300 magnets, as noted above, for both key and draw-stop actions. There are 130 miles of wire in magnets and cables, from No. 20 up to No. 34 B. & S. gauge. There are also 1,616 automatic combination knobs for setting combinations electrically throughout the organ. There are five automatic electric swell engines for the

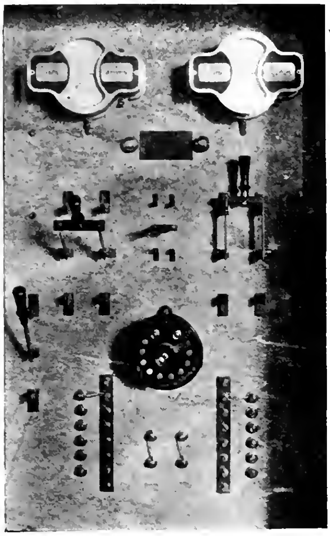

FIG. 3.—SWITCHBOARD.

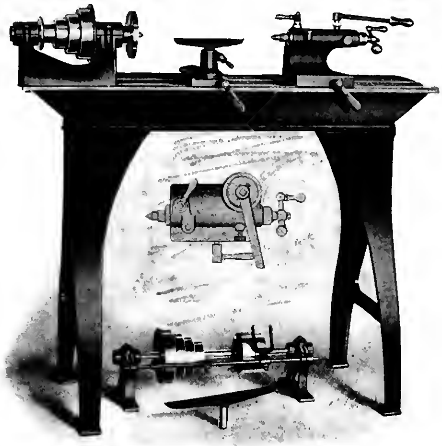
actuation of the swell shutters. There are above 7,000 open circuits in the organ. The company's special contact wire, of unusual costliness, is used in the key and coupler actions. The single-contact system is used, so arranged as to be durable and always reliable. The coupler action contacts clean themselves automatically, and all trouble is thereby prevented. The storage batteries used will have four cells of two volts each, with normal discharge of 50 amp for eight hours. There will be a motor-generator of 220 volts, direct current, with a capacity of 10 volts and 40 amp., to charge the batteries.

The switchboard (Fig. 3) has a voltmeter and ammeter to show the discharge voltage and strength of the batteries at all times. There will also be a polarity indicator, also a pilot lamp, which will indicate, to a certain extent, the strength of the batteries. There are also a voltmeter and an ammeter on the switchboard, one showing the voltage charging the batteries and the other showing the amount of the current going into the batteries. Switches are provided for throwing the generator on and off, and for throwing the current off the organ when not in use. The switchboard consists of a marble slab mounted in a handsome oak case with glass door for display purposes.

The entire instrument was built under the personal supervision of Mr. W. B. Fleming, the inventor of the system which bears his name.

Speed Lathes.

Embodied in the construction of the "Star" speed lathes are several new features of interest to users of this class of tools. The spindle is made from a crucible steel forging, has large hole and runs in large phosphor-bronze bearings, which are self-oiling and dust-proof. Each bearing is oiled by a double set of oiling wicks, which supply the bearing continuously with a liberal amount of oil. The surplus oil runs back into the oil wells, which prevents dripping and waste of oil. After the oil wells have been filled with a good quality of lubricating oil the lathe will then run for a long time



SPEED LATHE.

without further attention in this respect. The cone pulley has four steps, is turned inside as well as outside and is in perfect balance for high speeds. The head stock is the web pattern, strong and heavy.

The tail stock is the curved or cut-under pattern, the tail spindle having a new combination screw and lever motion with graduated dial. The dial is graduated by sixteenths and is valuable for drilling, counterboring, countersinking, etc., to a desired depth. The dial is movable and may be set at any point. To change from screw to lever motion it is only necessary to loosen the thumb screw releasing the spindle sleeve. The long hand lever can be lifted off when not in use. The tail stock has a long bearing on the ways and is firmly locked to the bed by a convenient lever—always attached—no wrench being required. The hand rest is provided with short and long T-rests, the rest socket and saddle are locked to the bed by a cam-locking device and the T-rest is held in its socket. Both are operated by levers always attached.

The bed is broad, deep and, being thoroughly braced by cross webs, is very stiff and rigid. The front way is flat and the back way is V-shaped. A convenient shelf is secured to the back of the bed for the reception of tools, etc. The countershaft has self-oiling and self-aligning shaft bearings, four step cone and tight and loose pulleys.

Each lathe is furnished with a face plate, two point centers, and, when desired, with slide rest, draw-in chuck and collets, etc. The 10-in. and 12-in. "Star" speed lathes are made by the Seneca Falls Manufacturing Company, 422 Water Street, Seneca Falls, N. Y.

Motor Starter for Variable Speed Work.

There is a large demand for a motor starter with which is combined a field regulating resistance for use with variable-speed motors, the speed range being obtained by field control. The requisites for this combination may be stated as follows:

1. That the field rheostat shall be so interlocked with the motor

FIG. 1.—MOTOR STARTER.

starter that the motor cannot be started under condition of weak field. 2. That the field rheostat must have twenty or more steps

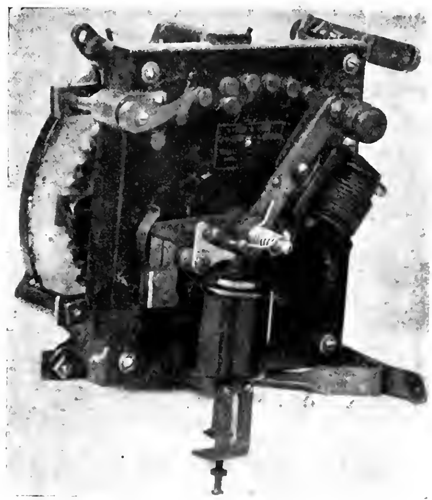


FIG. 2.—MOTOR STARTER.

(at least 20) in order to give even gradations of control. 3. That the starter must be entirely enclosed—to prevent short-circuits due to flying of metallic chips, etc. 4. That the starter must be equipped with an independent interlocking circuit-breaker which will protect the motor at all times, both during the period of starting and in the full running position. 5. That the no-voltage release must be independent of the field strength and connected across the armature terminals (it is not satisfactory to connect this no-voltage release across the line, as an arc will be formed at the switches when opened if so connected).

The Ward Leonard Electric Company has constructed a combination starter, as shown in the accompanying cuts, which is claimed to entirely fulfil all the above conditions, and also meets the specifications of the United States Government regarding such apparatus.

Outlet Switch Boxes.

Recent changes in the rules of the Underwriters' National Electrical Association affect outlet boxes. The Chicago Fuse Wire & Manufacturing Company, Chicago, New York and Buffalo, is making the "Union" outlet switch box designed to fit all makes of rectangular push button switches and flush receptacles. The "Union"

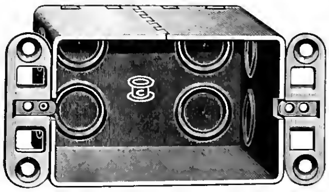

FIG. 1.—OUTLET SWITCH BOX.

box fulfils the latest requirements of the Underwriters in all respects and has "knock-outs" in the bottom and ends of the full thickness of the walls. Special attention is called to the fact that this box is formed from cold-rolled sheet steel of heavy gauge and is dove-tailed together, making it perfectly smooth outside, so that it will slip into a recess in plaster or woodwork, leaving the wall

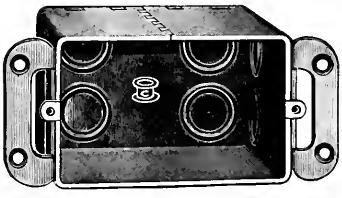

FIG. 2.—OUTLET SWITCH BOX.

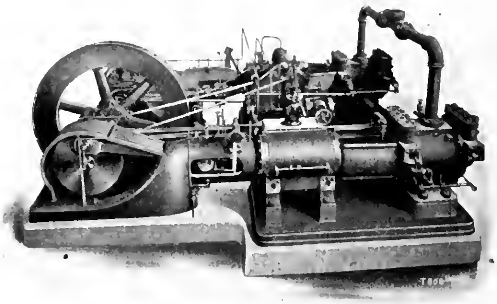
in perfect condition when the switch and plate are in place. The box is nicely finished in black enamel.

The Chicago Fuse Wire & Manufacturing Company further call attention to the adjustable feature in Fig. 1, making this box a perfect fit for any style, while Fig. 2 takes all switches having connections 3¼ in. c. to c. There is also a further style for specific plates and switches.

Compressed Air Power Plant at the St. Louis Exposition.

The central compressed air power plant at the St. Louis Exposition will contain two main compressing units, one cross-compound, two-stage Cincinnati-gear compressor, having 13 and 24-in. steam cylinders, 22 and 14-in. air cylinders and 24-in. stroke, with a displacement at 125 r.p.m. of 1,300 cu. ft. per minute, and one cross-compound, two-stage, Meyer-gear compressor, having 12 and 20-in. steam cylinders, 18 and 11-in. air cylinders and 18-in. stroke, with a displacement at 100 r.p.m. of 530 cu. ft. per minute. The first machine is to supply the general compressed air requirements of the Exposition, while the second is to supply the transportation exhibits. The larger machine is of special interest as being the first compressor of its type publicly exhibited, although a number of similar machines have been, and are being, installed in private plants. A 2,800-ft. machine is at the present time being placed in the Jersey City power house of the Central Railroad of New Jersey.

The general construction of one of these machines is herewith shown. The frames, as will be noted, are of massive construction, with a long bearing on the foundation, while the steam and air cylinders, joined in the direct line of thrust by heavy cast-iron housings, are also supported by bed plates under their entire length, the weight of each side being thus taken on two large bearing surfaces extending to the ends of the machine, avoiding the objectionable features of overhung cylinders, and giving the compressor great stability. The general construction is characteristic of the best grade of engine work, and comprises removable quarter boxes and main bearings, steel-forged connecting rods, with wedge take-up, specially large crank and wrist pins and cast-steel cross heads with adjustable babbitted slippers, top and bottom, working in bored guides. The reciprocating motion is of the simplest possible character, this simplicity in construction permitting low reciprocating weights without sacrifice of strength. These features allow satisfactory balancing, and, in connection with the long bearing on the foundations, insure an especially easy-running machine. The steam valve gear is of the four-valve type. Steam distribution is effected by means of short, double-ported, slide valves, working at either end of the steam chest on a valve face as close as possible to the cylinder bore, the port volume being restricted as far as the large valve area will allow. The exhaust valves are of the Corliss rotary type and are placed at the bottom of the cylinder. This construction has been followed in order to produce a valve gear having the essential advantages of a Corliss, namely separate passages for



COMPRESSED AIR PLANT.

the steam and the exhaust with corresponding reduction in cylinder condensation, together with short, straight ports and small clearance. On the other hand, the complicated Corliss releasing gear has been eliminated, the action being positive throughout.

The air valve gear is, however, the distinguishing feature of this machine, combining in a very ingenious manner the positive action, noiseless operation and durability of the mechanically-moved valve with the elasticity of the poppet valve. The noise and rapid wear of the poppet valve, due to the impact of the valves closing at the reversal of stroke, is eliminated by mechanically closing the passages underneath the poppet valve, and leaving a cushion of air upon which the latter seats. The three fixed points in the compression cycle, namely the opening of the inlet, the closing of the inlet, and the closing of the discharge, are positively and mechanically controlled; the opening of the discharge, which is the only variable point in the cycle, is controlled by the automatic poppet valves, which are relieved, however, of the necessity for quick closing, and are consequently free from the objectionable features of noise and rapid wear.

The cards from one of these machines, operating at a speed of 150 r.p.m., show a steep expansion line on the air cards, indicative of the small clearance and high volumetric efficiency of the machine, the large valve area being indicated by the practical coincidence of the inlet and atmospheric lines and by the uniform discharge line. The rounded admission of the steam cards, which might in ordinary engines be deemed objectionable, is due to the maker's practice of giving the steam valves a slight negative lead to offset the expansion pressure at the beginning of the air cards. These machines are built by the Laidlaw-Dunn-Gordon Company, of Cincinnati, Ohio.

NEWS OF THE WEEK.

Financial Intelligence.

THE WEEK IN WALL STREET.—The tone of the stock market was heavy, and there was a general unsettled feeling, due to unfavorable war news, poor reports about the iron trade prospects and absence of outside support. The death of Mr. W. C. Whitney occasioned some scattered selling of stocks of traction and other interests with which he was formerly identified, Brooklyn Rapid Transit being particularly weak at the close. United States Steel securities were quite heavy for a time on unfavorable reports as to the steel and iron trades and on talk of poorer earnings. Under the influence above mentioned Brooklyn Rapid Transit suffered a net loss of 6¾ points on the week's trading, which was active, 149,870 shares having been sold. The closing quotation was 40⅜, which was only ⅜ above the lowest figure of the week, the highest being 47⅜. Metropolitan Street Railway ranged in price between 117 and 120½, closing at 117½, this being a net loss of 3½. Manhattan Elevated closed at 142¼, a loss of 1¼. The electrics—General Electric, Westinghouse, Western Union and Telephone—were all down, General Electric, however, suffering the smallest loss of all, viz., ⅛ point, closing at 170. Westinghouse common lost 6 points, closing at 161; Western Union, 1, closing at 87¾, and American Telephone and Telegraph, 2 points, the last price of the week being 126. In the curb market nearly everything was reactionary in sympathy with the downward tendency in the stock market rather than because of any special developments. In Electric Boat holders are firm, asking 25, while only 10 is bid. Electric Vehicle is held at 10, with 8 bid. New York Electric Vehicle Transportation is quoted at 5½ bid, with 6 asked. Following are the closing quotations of February 9:

CUYAHOGA TELEPHONE REPORT.—The comparative statement of earnings and expenses for the year ended December 31, 1903, for the Cuyahoga (independent) Telephone Co. of Cleveland, follows:

	1903.	1902.	Changes.	
Gross	$396,490	$385,852	Inc.	$10,638
Exp. and taxes	216,460	229,709	Dec.	13,240
Net	$180,030	$156,143	Inc.	$23,887
Charges	129,259	155,600	Dec.	26,341
Surplus	$50,771	$543	Inc.	$50,228
Employes' share of profits (for six months)..	4,155	......	Inc.	4,155
Net surplus	$46,616	$543	Inc.	$46,073

JOHN T. HUNT.—A meeting of creditors of John T. Hunt, who did business as Zimdars & Hunt, electrical contractors, at 127 Fifth Ave., New York, who made an assignment recently, was held at the office of Goeller, Shaffer & Eisler, 207 Broadway, and a committee was appointed to make an examination and report a basis of settlement. The liabilities are about $50,000 and assets estimated at from $28,000 to $30,000. Hunt started in business in 1879 with C. E. Zimdars as a partner. They continued together until 1887, when Mr. Zimdars withdrew and the latter's wife became partner up to February, 1903, when Mr. Hunt bought her interest, and he has since continued the business alone under the old firm style. The causes of the assignment were the long strike in the building trade last summer and fall, and the recent stringency in the money market.

STANDARD UNDERGROUND CABLE CO.—The annual report of this company, as noted on next page, makes an excellent financial showing. The board of directors elected for the ensuing year is as follows: Mark W. Watson, John B. Johnson, James H. Willock, Robert Pitcairn, J. N. Davidson, John Moorhead, B. F. Jones, Jr., Joseph W. Marsh and W. A. Conner. The only change in the board is represented by the election of W. A. Conner, who has been at the head of the manufacturing department of the company since 1884. At the meeting of the board of directors for purpose of organization, held on January 29, the former officers were re-elected as follows: Mark W. Watson, president; Joseph W. Marsh, vice-president and general manager; Frank A. Rinehart, treasurer, and C. M. Hagen, auditor.

ALBANY TRACTION MORTGAGE.—The Board of Directors of the United Traction Company, operating the traction system of Albany and Troy, has approved of a financial plan, the main feature of which is the issue of a mortgage for $6,500,000. The issue is to be used for the redemption of outstanding bonds of the subsidiary companies as they mature and to pay for improvements already made and in progress, while $1,339,000 is reserved for future extensions and betterments. Nine hundred thousand dollars in bonds will be offered for sale at this time. The Central Trust Company of New York is to be trustee under the mortgage. The plan contemplates, it is said, some extensions or consolidations with other roads.

BATAVIA, N. Y., LIGHTING TROUBLES.—Under a decision rendered by Justice Truman C. White and filed in the County Clerk's office at Batavia, N. Y., in the Supreme Court action brought by Mrs. Frances A. Baker, of Rochester against the Consolidated Gas and Electric Company of Batavia and others, the foreclosure is ordered of a second mortgage for $20,000 on the company's property and Edward C. Atwater, of Batavia, an attorney who is secretary of the Batavia Carriage Wheel Company, has been appointed receiver of the Consolidated Company.

DIVIDENDS.—The directors of the Niles-Bement-Pond Co. have declared the regular quarterly dividend of 1½ per cent. on the preferred stock, payable February 15. A semi-annual dividend of 4 per cent. was also declared on the common stock, 2 per cent. payable March 19, and 2 per cent. June 18. The directors of the Pratt-Whitney Co. declared the regular quarterly dividend of 1½ per cent. on the preferred stock, payable February 15.

MARCONI WIRELESS TELEGRAPH business is reported increasing to such an extent that the Marconi Wireless Telegraph Company of America shows the astonishing fact that the business passing through Marconi shore stations in America to and from Atlantic steamers, had gained 350 per cent. in December, 1903, as compared with 1902. At this rate a good showing ought to be made for the year.

Commercial Intelligence.

THE WEEK IN TRADE.—Trade and transportation are affected throughout the West by the weather conditions, while in the East retail winter trade is reported good. As to spring trade, however, some irregularity is noted. The market in the principal commodities was excited. War news was the ostensible cause of this, although speculation is responsible, too, to some extent. Wheat supplies are 25 per cent. smaller than a year ago; country offerings are light; milling requirements have been heavy and a large short interest in May has been forced to cover at a loss. Taking the situation as a whole, however, there is every reason for confidence as to the spring outlook, the irregularities noted here and there being only superficial and temporary. There is little change in the iron trade. Snow blockades have had the effect of reducing supplies and strengthening prices in the East, but buying is limited. Finished products do not show any special activity. The sales of 40,000 tons of rails to a Canadian railway is reported at a price $5 below the rate asked the American roads. Plates and structural material are quiet; wire is selling well, however. Agricultural hardware is in good demand in the West. Other metals—copper, tin and lead—are all lower. In the copper market, there was greater weakness, and official quotations have been marked down ¼c. Lake is quoted at 12⅜ a 12⅝c.; electrolytic 12¼ a 12½c.; casting stock 12¼ a 12⅝c. The business failures during the week ending February 4 were about the average in number, *Bradstreet's* making the aggregate for the United States 216, as against 242 the week previous, and 208 the corresponding week in 1903.

ELECTRIC POWER FOR BRIDGE.—The McCombs Dam bridge across the Harlem River, New York, has one of the largest and handsomest highway draw spans ever built. It is 400 feet long, and has a 40-foot roadway and two sidewalks each nearly 10 feet wide. The moving mass weighs about 2,200 tons, and until now has been operated by a 40 hp oscillating cylinder steam engine with differential gear reducing its speed from 19 to 1. The ends of the bridge were lifted by a separate mechanism with hydraulic jacks driven from an accumulator in the engine room. It was locked by hydraulic centering rams. About two minutes was required to open or close the draw, and the cost of maintenance of the mechanism was very large. In order to simplify and expedite operations, the engine has been replaced by a 20 hp alternating-current motor furnished by the General Electric Company, and believed to be the first one of this size and character applied to such purposes. The motor is also connected by a clutch to a system of gears and shafts, which extend from the centre of the bridge to both ends and operate toggle joints which replace the hydraulic lifting apparatus. The latch has also been replaced by an automatic device designed by Boller & Hodge, New York. Only one man will be required where three were previously needed, and it is believed that the bridge can be swung open or shut in one minute or less. The improvements have been made by the employees of the Department of Bridges, New York, Mr. Martin Gay, assistant engineer in charge of structures on the Harlem River. The machine work was done in the Brooklyn Bridge machine shops.

MEXICAN WATER POWER PROJECTS.—There are a number of new projects to develop water power in Mexico for electric light and power purposes and for irrigation. Theodore V. Peereborm and associates have acquired a concession from the Mexican authorities for the purpose of utilizing 40,000 liters of water per second from the Janapa River located near Cordoba in the state of Vera Cruz. The power will be used for generating current for light and power use in that vicinity. Another scheme is to build a plant on the Rio Grande River, in the State of Chihuahua, permission having been secured by Edward T. Le Clair. The franchise concedes the use of 15,000 liters per second. Fernando Gonzalez proposes to utilize the water of the Amacusac River for the irrigation of the valleys of the Iguala and Cocula, State of Guerrero. Charles Connant plans to use 20,000 liters of water per second from the Yagin River in the district of Guaymas, State of Sonora. His is, also, an irrigation scheme. The Walthalla Colonization Company anticipates the construction of a large irrigation plant which will be used to flood a large area of agricultural land in the vicinity of Naranja, State of Jalisco.

MEXICAN TRACTION PLANS ACCEPTED.—The plans of the Mexican Traction Company for the electrical conversion of the Circuito de Barrios tramways, a mule line operating in the heart of Mexico City, have been approved by the municipal authorities. The company has made application for permission to extend the Barrios line into the Colonia del Paseo, and the Colonia Nueva del Paseo and also into various streets of the American colony. Mr. R. M. McAdoo, of 15 Wall Street, is president of the company. He is now in Mexico. Pittsburg capital will build the system which will aggregate more than 100 miles. The initial capacity of the power plant will be 2000 hp. Twenty 40-feet cars with four motor equipments of 56 hp each will be ordered in the first instance. The Pittsburgers primarily interested in the enterprise are James B. Oliver, Julius Breler, Reuben Miller, James H. Park and Frank B. Smith, all of whom outside of Mr. Oliver are prominently identified with the Crucible Steel Company. A. T. Montmorency, of Mexico City, is the chief engineer of the company. The entire system is expected to be in operation in about twelve months.

STANDARD UNDERGROUND CABLE CONFERENCE.—The annual conference of the branch office managers of the Standard Underground Cable Company with the general sales, the manufacturing, the construction and the executive departments of the company, was recently held in the general offices of the company in the Westinghouse Building, Pittsburg, the session covering three days. The report of each manager for the year 1903 and the business prospects for the year 1904 was presented and discussed, together with ways and means for rendering more efficient service in every department to the customers of the company, who now number considerable over 1,000. A pleasant social feature of the occasion was a theatre party given by Mr. J. W. Marsh, vice-president and general manager of the company, to the visiting managers. The branch office managers attending the meeting were Mr. Charles J. Marsh and Mr George L. Wiley, from the New York office; Mr. Frank Clark Cosby, from the Boston office; Mr. T. E. Hughes, from the Philadelphia office, and Messrs. J. P. Wiley and E. J. Pietzcker, from the Chicago office.

PACIFIC COAST POWER TRANSMISSION.—The Corona (Cal.) Gas and Electric Company will run a three-mile transmission line to the Auburndale tract to furnish power there and at intervening points. George and Albert Le Gaye, who have bought 300 acres of the former town site in the Auburndale tract, of W. H. Jameson for $7,000, will use a greater part of it for raising alfalfa. They will sink wells and install a pumping plant. The dynamos are now running almost the full capacity. The company intends to duplicate the plant as soon as necessary.

JAPANESE MUNICIPAL TRACTION PROJECT.—The municipal authorities of Osaka—the principal commercial city in Japan—propose to construct an extensive electric traction system. City bonds to the amount of 3,500,000 yen—about $1,250,000—are to be issued for the purpose of capitalizing the undertaking. This is the first instance of the construction and operation of a street railway being mooted by a Japanese municipality, all such enterprises so far having been undertaken by private capitalists. We trust that the war will not interfere with the enterprise.

MEXICAN ELECTRIC RAILWAY PROSPECT.—The Mexican advices state that a local syndicate is being organized in the City of Puebla, State of Puebla, Mexico, with a view to constructing an electric railway between that important Mexican city and Totinshuecan. Francis Barnard, the manager of the Ferrocarril Urbano de Puebla and the Ferrocarril Industrial de Puebla, is primarily interested in the project. The length of the road will be about seven miles.

PARSONS TURBINES FOR SYDNEY.—Parsons steam turbines have been ordered for installation in the extension of the Ultimo central power station of the Sydney city and suburban electric traction system, operated by the New South Wales government. The existing power house equipment was contracted for with the General Electric Company, the engines being of Allis build. The additional installation will have a capacity of about 5000 horse power.

AMERICAN TELEPHONE ORDERS.—Among switchboard shipments recently reported by the American Electric Telephone Company of Chicago, are the following: Hotchkiss, Colo., 100 line express; Neodesha, Kan., 100 line special; Wauseon, Ohio, 100 line express; Urbana, Ohio, 105 line express; Topeka, Kan., two shipments 100 line express; Plainsboro, N. Y., two, 30 capacity special; Milwaukee, Wis., 100 line express.

JAPANESE STREET RAILWAY PROJECT.—A scheme to construct an electric railway between Kyoto and Otsu, as proposed by Mr. Asano, of Tokio, and other Japanese capitalists has, according to advices just received here, been approved by the leading business interests in both cities, and a syndicate is in process of formation for the purpose of carrying out the enterprise. The length of the road will be some 30 miles.

YUCATAN ELECTRIC TRACTION PROJECT.—The United Railways of Yucatan which operates the majority of the steam roads in Yucatan, propose to convert the existing mule roads in the capital city, Merida, into electric traction, and to construct more lines. The New York purchasing agents for the United Railways are Thebaud Bros., 87 Broad Street. It is expected that some 30 miles of track will be electrically operated.

EQUIPMENT FOR NOME PLACER MINING.—The Puritan Gold Mining Company of Nome, Alaska, of which W. H. Powell, of Milwaukee, is president, is about to purchase considerable electrical equipment to be used for operating dredges at the company's property, which is located about two miles from Nome City. The company is incorporated under the laws of Wyoming with a capital of $2,000,000.

GENERAL ELECTRIC MOTORS FOR MEXICAN MINE PUMPS.—The General Electric Company has secured a contract for a number of motors varying in capacity up to 200 hp for direct connection to centrifugal pumps built by the International Steam Pump Company, for installation in Mexican mines.

NEW TELEPHONE SYSTEM FOR MANILA.—The Manila Telephone Company, which operates the present system in the Philippine capital, is to modernize and considerably extend the installation which will necessitate the purchase of a large quantity of equipment on this side.

STEEL STACK FOR MANILA POWER HOUSE.—The Riter-Conley Manufacturing Company, of Pittsburg, Pa., has secured the contract for the large steel stack for the power house to be built by the Manila Electric Lighting and Railroad Corporation.

BALL ENGINE ORDER.—The Continental Coal Company, Columbus, Ohio, has recently placed in operation two 400 hp heavy duty side crank engines, built by the Ball Engine Company, Erie, Pa., at its mine, No. 255, Jacksonville, Ohio.

General News.

THE TELEPHONE.

TOMBSTONE, ARIZ.—The Tombstone Telephone Company has been incorporated by E. T. Ijams, E. U. Ijams, W. C. McFarland and others. The capital is $180,000.

CONWAY, ARK.—The Conway Telephone Company has been incorporated with a capital stock of $10,000. L. H. Pyle is president.

DARDANELLE, ARK.—The Arkansas Telephone Company has been incorporated with a capital stock of $20,000. The incorporators are: J. B. Crownover, W. R. Hayden, A. L. Blackwell, C. W. Brown, A. D. Perry and Geo. N. Goodier.

ANAHEIM, CAL.—The City Council has adopted a resolution to advertise for sale the telephone franchise requested by the Home Telephone Company.

SAN FRANCISCO, CAL.—The Sunset Telephone & Telegraph Company has been incorporated with a capital stock of $3,000,000, the amount actually subscribed being $10,000. The object of the company is to deal in all kinds of electrical supplies in the Pacific Coast states. The company is to build lines throughout this section of the country, the total length of which is given as 1000 miles. The directors are George S. Ladd, John I. Sabin, Louis Glass and others, of San Francisco.

ATHENS, GA.—It is stated that a new independent telephone system will be established here. Mr. L. D. Goodrum, of Pennsylvania, is promoting the enterprise.

MIDDLETOWN, ILL.—The Middletown Mutual Telephone Company has been incorporated with a capital stock of $2500. The directors are: Thomas Dorgan, P. J. England and others.

TAMPICO, ILL.—The Tampico Farmers' Mutual Telephone Company has been incorporated with a capital stock of $4900. The directors are: W. M. Maloney, A. C. Hunter and others.

DANVILLE, ILL.—The Vermillion County Telephone Company, it is stated, has bought out the Central Union system. This is thought to be the first instance on record where a local company has compelled the surrender of the Central Union. The capital stock of the new company was recently increased from $150,000 to $4,000,000.

CHICAGO, ILL.—The stockholders of the Automatic Electric Company have voted to increase the capital stock of the company to $2,000,000, making the total $5,000,000. This is the company that is manufacturing the equipment for the Illinois Tunnel Company's telephone system in Chicago. It is also at work on orders for thirty other exchanges throughout the country.

CHERRYVALE, IND.—The Cherryvale Telephone Company has been incorporated with a capital stock of $350.

PORTLAND, IND.—There is every indication of a telephone war being inaugurated in this city. The Bell Telephone Company is preparing to establish an exchange in opposition to the Home Telephone Company.

INDIANAPOLIS, IND.—A number of telephone companies in this State have abolished the custom of making a "morning test." Many patrons objected to the unnecessary annoyance and since the practice has been discontinued the service is equally as good.

NEWCASTLE, IND.—It is stated that the independent companies in Henry County will probably be consolidated in the near future. There are nearly 4,000 independent telephones in the county, and the object of the consolidation will be the exchange of service for mutual interest.

SWEETZER, IND.—At the annual meeting of the Sweetzer Telephone Company new directors were elected as follows: L. M. Hoggatt, J. B. Reed, A. Bechtel, J. C. Lake and Louis Oyler. The new board in turn elected Mr. Hoggatt president, Mr. Reed treasurer, and Mr. Bechtel secretary. The report for the year was very gratifying.

LAGRANGE, IND.—The Northern Indiana and Southern Michigan Telephone Company has completed arrangements for better service. The office at Lima will be made an all night office. The company began February 1st to give the market and weather reports over its 14 party lines from Lima to all its subscribers. These reports and the night service has increased the demand for telephones.

SPIRIT LAKE, IA.—The Midland Telephone Company will install a local exchange in this place.

CLARE, IA.—The Fort Dodge Telephone Company contemplates the installation of an exchange in this place.

CEDAR FALLS, IA.—The City Council has granted a franchise for a mutual telephone company in this place, as proposed by Mr. R. A. Davison.

SIOUX CITY, IA.—The Independent Telephone Company has the contract for the construction of a toll line from Odebolt to this city, a distance of 60 miles, and another to Lemars, 25 miles.

FORT DODGE, IA.—The Fort Dodge Telephone Company has elected officers for the coming year as follows: O. M. Oleson, president; C. D. Koch, vice-president; L. A. Thorson, secretary; E. G. Larson, treasurer.

WEBSTER CITY, IA.—Ten different telephone companies operating in Hamilton County have been consolidated. They are the Kamrar Co., the Jewell-Wall Lake Co., the Ellsworth Mutual Co., the Williams Co., the Stanhope & Northeastern Co., the Randall Co., the Jewell & South Cairo Co., the Jewell & Northwestern Co., the Stratford Independent Co., and the Blairsburg Co.

FALL RIVER, KAS.—The Fall River Telephone Company has been incorporated with a capital stock of $3000.

AUGUSTA, ME.—The Amazon Wireless Telegraph & Telephone Company has been organized here with a capital stock of $1,000,000, of which nothing has been paid in. The officers are J. Berry, Augusta, president, and L. A. Burleigh, Augusta, Treasurer.

READING, MICH.—The Central Telephone Company has been incorporated with a capital stock of $10,000.

MARQUETTE, MICH.—Crawford & Sons, timber operators of Cedar River, may build a telephone line from Cedar River to Stephenson in the spring.

DETROIT, MICH.—The stockholders of the Co-operative Telephone Company have approved a bond issue of $50,000 for extensions and improvements.

MURDOCK, MINN.—A telephone line is projected from Murdock to Louriston and Buffalo Lake.

HOWARD LAKE, MINN.—The Howard Lake Telephone Company will make a 10-mile extension in the spring.

MINNEAPOLIS, MINN.—The Twin City Telephone Company has declared the eighth quarterly dividend on preferred stock at the rate of 7 per cent. per annum.

ELKO, NEV.—The Northern Telephone & Telegraph Company has been incorporated with a capital stock of $10,000 by J. G. Taylor, R. H. Mallett and others. The company is already operating a line between Tuscarora, Edgemont, White Rock and Columbia, and will extend it to other points north.

MIDDLETOWN, N. Y.—Te directors of the Orange County Telephone Company have re-elected the following officers: President, Charles Higham; vice-president, A. B. Wilbur, and secretary, W. C. Ramsdell.

WILMINGTON, N. C.—It is announced that the lines of the Long Distance Southern Bell Company will be extended from Wilmington to Florence, S. C., a distance of 110 miles. The Bell Company is taking down the wires of the recently absorbed Interstate Company at Wilmington.

MIFFIN, OHIO.—The Mifin and Widowville Telephone Company has increased its capital from $1000 to $5000.

CLEVELAND, OHIO.—The Telephone Hygenic Company has been incorporated with a capital stock of $100,000. The directors are F. B. Williams, T. H. Hogsett and others.

IRONTON, OHIO.—Eastern capitalists have purchased the property of the Lawrence Telephone Company, having exchanges here, at Ashland, Catlettsburg, Russell and Rush, Ky., and minor points. It is stated semi-officially that the Central Union Telephone Company is the purchaser.

HARRISBURG, PA.—The annual report of the Pennsylvania Telephone Company shows that 368 miles of toll pole lines were rebuilt, and 758 miles of copper metallic circuits substituted for iron wire.

CHESTER, PA.—The Keystone State Telephone & Telegraph Company has begun a general system of renovation along its lines in the county. Two new trunk lines are being constructed to Chester from Philadelphia. In connection with this, the exchange will be removed from Moore and located either in Lansdowne or Darby.

WASHINGTON, PA.—J. T. Behout, of Claysville, has purchased all of the property of the Federal Telephone Company in Buffalo, Blaine and Donegal townships. Mr. Behout also purchased interests in the Claysville Telephone Company, which system will be operated in connection with that portion of the Federal system acquired by him. Exchanges will be established at Claysville, Taylorstown and various other points in the townships named.

COLMAN, S. D.—The Colman Electric Telephone Company has been incorporated with a capital stock of $10,000.

MEMPHIS, TENN.—The Memphis Long Distance Telephone Company has executed a mortgage for $1,000,000 with the Tennessee Trust Company as trustee; bonds to this amount to be floated to meet expenses, complete the plant and acquire other properties.

ELKHART, TEX.—The Elkhart Telephone Company which was recently organized here has constructed and put into operation a telephone line to the towns of Slocum and Denison Springs, a distance of fifteen miles. The line will be extended.

MERHERRIN, VA.—The Lunenburg Telephone Company has increased its capital from $500 to $5000.

JANE-LEW, W. VA.—The Beeghley Telephone Company of this place has been incorporated with a capital stock of $50,000. The incorporators are: Lloyd Beeghley, Hattie Beeghley, R. A. Beeghley, Weston, W. Va., Mary A. Swisher, Charles Beeghley, Jane-Lew, W. Va.

DAVENPORT, WASH.—The Creston & Sherman Telephone Company has been granted a telephone franchise on the public highways of the county.

WHEELING, W. VA.—The National Telephone Company has completed connections with the South Penn Telephone & Telegraph Company operating between Waynesburg and Uniontown. The company has also completed a direct line to Mannington, where connection is made with the system of the Consolidated Telephone Company, and the line to Wellsburg is nearly completed.

JANESVILLE, WIS.—The Rock County Telephone Company has decided to extend its lines.

LEEDS, WIS.—The Leeds Farmers' Telephone Company has increased its capital from $5000 to $10,000.

RIVER FALLS, WIS.—The St. Croix Valley Telephone Company has increased its capital stock to $1500.

MADISON, WIS.—The Rhinelander Mutual Telephone Company has increased its capital stock to $10,000.

GRAFTON, WIS.—The Grafton Telephone Company has been incorporated with a capital stock of $4000. The directors are J. G. Buck, F. C. Mintzlaff and others.

RIDGELAND, WIS.—The Dunn County Telephone Company of this place has been incorporated with a capital stock of $10,000 by M. L. Randall, A. L. Pongratz and J. R. Ferguson.

Electric Light and Power.

DOUGLAS, ARIZ.—A company has been formed here for the purpose of establishing another electric light and power plant. It has a capital stock of $60,000. H. C. Mayer is manager of the new company. The stockholders are F. S. Douglas, W. G. McDonald, A. S. Pierce, C. J. Lachance, D. A. Richardson and others.

SAN FRANCISCO, CAL.—The United Gas and Electric Company held its annual meeting on January 21. The officers elected were: J. E. Green, president; C. E. Green, vice-president, and C. H. Pennoyer, secretary. R. J. Davis replaced George A. Nichols as one of the remaining directors.

MACOMB, ILL.—The Brookfield Gas, Electric & Heating Company of this place has increased its capital stock from $25,000 to $50,000.

AURORA, ILL.—The Aurora, Elgin and Chicago Light, Heat and Power Company has been incorporated, with a capital of $5000. Incorporators: Edwin C. Faber, John T. Huntington and William F. Harvey.

FT. WAYNE, IND.—The City Council has granted a 31-year franchise to the Ft. Wayne Electric Light and Power Company at $70 a year for street lights and 10 cents per kw. for private current. There has been a six months fight over this franchise owing to a sentiment favoring a municipal ownership plant.

JACKSON, KY.—An accident to the engine in the electric light station recently destroyed that machine to such an extent that the city was left in total darkness.

LEWISTON, ME.—Work is soon to be commenced on the new dam across the Androscoggin River. All of the electric power apparatus is on the ground, and it is expected that about 10,000 horse power will be available for distribution in Lewiston and Auburn early in the fall of this year.

ITHACA, MICH.—The managers of the Ithaca Light & Power Company shut down the plant recently on account of the high price of coal, which they claim prevents them from running the plant at a profit, and rather than lose money they decided to close down indefinitely.

GLASGOW, MONT.—Preliminary surveys are in progress for the construction of water works and an electric light plant. A. W. Mahon is the engineer.

LIVINGSTON, MONT.—The new electric light plant of the Livingston Water Power Company, which takes the place of the one destroyed by fire on November 29 last, is now in operation. As yet no street lamps are in service and there will be none until the city pays up its back bills for street lighting. The streets are, therefore, unlighted.

SANTA FE, N. M.—The Capital City Light and Power Company has taken the preliminary steps looking to extending its transmission lines to the city of Albuquerque and Las Vegas. It is proposed to furnish those places with light and power for municipal and commercial purposes. The plans of the company contemplate the construction of a large electric power plant at the Pecos River Falls, situated fourteen miles from Santa Fe. Among those interested in the company are Colonel W. S. Hopewell, manager of the New Mexico Fuel and Iron Company, Santa Fe; J. C. Bonner, of Toledo, Ohio; J. W. Miller, mining engineer, of Denver, Colo., and A. R. Gibson, of Santa Fe.

GREENE, N. Y.—The citizens have voted to issue $4500 bonds, to complete the electric light plant.

HILTON, N. Y.—A. M. Lawrence, of Clyde, submitted an offer to this village to establish an electric light plant.

CATSKILL, N. Y.—The Catskill Illuminating & Power Company has increased its capital stock from $65,000 to $100,000.

BROOKLYN, N. Y.—Bids will be received February 15 by C. B. J. Snyder, Superintendent of School Buildings, New York City, for installing electric equipment in the manual training high school.

CLINTON, N. Y.—The capital stock of the Clinton Electrical Company has been increased by $15,000, and steam will be installed at the power house as soon as weather will permit. Work will be commenced with a view to increasing the water power.

LEROY, N. Y.—The Leroy Hydraulic Electric Company has petitioned the courts for permission to change its name to Leroy Hydraulic Electric Gas Company. The first named company about a year ago purchased the old gas plant and the street lighting plant, and it is now proposed to consolidate the two concerns under the latter title above given.

WINSTON, N. C.—The city of Winston has contracted with the Fries Power and Manufacturing Company for seventy arc lights at $60 per light per year, the contract covering three years, beginning March 31, 1904.

NEWTON, N. C.—Shields, Sons & Co., of Providence, R. I., have secured an option on a valuable water power on the Catawba River near here, and it is said will begin a big electric development to supply power to neighboring cotton mills.

TOLEDO, OHIO.—At the annual meeting of the Toledo Railways & Light Company the present officers and directors were re-elected for the ensuing year. The annual report of President Everett showed that the gross receipts were $1,663,794, an increase of $204,702 over the previous year. The operating expenses were $856,526 as compared with $726,779 in 1902; and the net earnings were $807,279 against $123,312 in 1902.

HARRISBURG, PA.—At the annual meeting of the Harrisburg Light, Heat & Power Company the following named officers were elected:: President, E. Z. Wallower; vice-president, Harry C. Ross; secretary and treasurer, Harry W. Stone; general manager, Charles C. Kinter.

READING, PA.—The following named officers have been elected by the Reading Electric Light & Power Company: Jerome L. Boyer, president, and J. H. Righter, secretary. The company will be twenty-one years old on March 8, and during its existence it has declared 62 dividends amounting to $565,000. This is equal to 200 per cent. on the original capital stock.

PHILADELPHIA, PA.—Judge McPherson, in the United States Circuit Court has issued a decree of foreclosure ordering the sale of the Lehigh Power Company's plant in and around Easton, Pa., to satisfy the claim of the Central Realty, Bond & Trust Company, trustee of the mortgages securing the bondholders. This action was taken on account of the default of the company in the payment of interest due on its bonds amounting to $325,491.25. Mr. Russell C. Stewart was appointed special master to conduct the sale.

WEBSTER, S. D.—The council committee is considering the matter of increasing the capacity of the electric light plant here.

MITCHELL, S. D.—J. B. Mickellsell and Fred. Fairchild have purchased the local electric light plant, and will install additional machinery.

MEMPHIS, TENN.—The Memphis Electric Supply Company has increased its capital stock from $5000 to $50,000.

WACO, TEX.—The citizens have voted to issue bonds for an electric light plant, water works and a sewerage system. F. H. Meader is recorder.

WILLS' POINT, TEX.—The Wills' Point Electric Light Company has been organized with a capital stock of $10,000. The incorporators are O. L. Johnson, Charles E. Brown and W. B. Rogers, all of Wills Point.

MARBLE FALLS, TEX.—It is reported that the falls of the Colorado River at this place are to be utilized for generating electric power for an electric plant that may be installed here. The names of the parties interested are not given.

CISCO, TEX.—The Cisco Electric Light Company has been organized here with a capital stock of $10,000 for the purpose of installing and operating an electric light and power plant. The incorporators are W. A. McSpadden, Aaron L. Mayhew and Abner L. Mayhew, all of this place.

FILLMORE, UTAH.—The city officials are considering the installation of an electric light plant here early in the spring.

ORANGEVILLE, UTAH.—The towns of Orangeville and Castledale are considering the construction of an electric light plant and a joint committee consisting of A. G. Van Buren and J. B. Crawford, of Orangeville, and W. J. Seeley, of Castledale, have been appointed to investigate the matter.

WATERVILLE, WASH.—The City Council has entered into a 15-year contract with George H. Gray & Son, of Entiat, to furnish electric light and power to Waterville at $50 per horse power per annum. The plant is to be in operation by September 1.

OCONOMOWOC, WIS.—The Council has decided to secure bids for improving the electric light plant.

SHELL LAKE, WIS.—The citizens have voted to borrow from the State $10,000 for an electric light plant and water works.

BELOIT, WIS.—The Beloit Electric Lighting Company will expend about $10,000 in improvements. J. S. Allen is manager.

WEST ALLIS, WIS.—The Village Board has granted to the Milwaukee Light, Heat and Traction Company a perpetual franchise for lighting. The company was given a 3 year contract for electric lighting.

PORT ARTHUR, ONT.—At a recent meeting of the council for the town of Port Arthur, the question of further developing the power on Current River received favorable consideration. It is the intention of the council to utilize from 8000 to 10,000 horse power, and to offer the surplus power at a low rate for manufacturers. It is said that taking the cost of the power development on a 5 per cent. interest basis the interest on borrowed cash for this purpose, which the town now pays, brings the cost down to about $4 per horse power per annum.

SHERBROOKE, QUE.—The shareholders of the Sherbrooke Electric Company have decided to accept the offer of the city to purchase the company's electric light plant and property for the sum of $200,000, provided the city will also take over the gas property of the company.

MONTREAL, QUE.—At the annual meeting of the shareholders of the Shawinigan Water and Power Company, the treasurer reported that the company was now selling in Montreal 6000 horse power, and at Shawinigan Falls, 20,000; that there was still a large surplus of power in the development at the Falls, the total being estimated at 100,000 horse power. The operation of the power plant at Shawinigan Falls had proved satisfactory, and the successful transmission of power to Montreal had demonstrated the commercial feasibility of transmission to any point within a radius of 100 miles of the Falls. The company was in receipt of applications for large amounts of power, and extensive additions to its electrical plant will be made.

MONTREAL, QUE.—The Montreal Light, Heat and Power Trust now includes the Montreal Gas Company, the Royal Electric Company, the Montreal and St. Lawrence Light and Power Company, the Imperial Electric Light Company, the Lachine Rapids Hydraulic and Land Company, the Standard Light and Power Company, the Citizens' Light and Power Company, and the Temple Electric Company. Further combinations are looked for, notably that of the Montreal Street Railway Company with which the combine is already closely allied. This trust was formed for the ostensible purpose of cheapening production by combination, but the experience of consumers shows that the cheapening of light and power to them has not resulted. The combination now controls all the lighting and supply of power of Montreal, St. Henri, Ste. Cunegonde, St. Louis, Westmount, Maisonneuve and Cote St. Paul, with a population of 322,327. It also controls the public lighting of the city of Montreal under a contract running until January, 1909. At a recent meeting of the Montreal Board of Trade, it was unanimously decided that electric light and power were too dear, and that steps should be taken to put an end to such monopolies as that of the Montreal Light, Heat and Power Company. It was stated that this company was at present charging its customers four times as much for power as the combination paid for its supply received from the Shawinigan Falls Company.

The Electric Railway.

WATSONVILLE, CAL.—W. J. Rogers has applied for a franchise to construct and operate an electric railway over certain streets in Watsonville. Bids for the franchise will be received up to 8 p. m., February 17. S. W. Coffman is City Clerk.

EAST ST. LOUIS, ILL.—The new power house of the East St. Louis & Suburban Railway Company is expected to be completed some time in March. The company then will abandon its three small outside stations, and depend entirely upon the new plant for power with which to run its cars. During the year the company has introduced a great many improvements. A unique feature has been the installation of a complete telephone system on its suburban lines. All the trolley poles have been numbered, and on every fifteenth pole a telephone connection has been hung. Each car also is equipped with a portable telephone, which can be quickly attached to the pole connection and communication entered into with the sheds, power stations, general office or superintendent's residence. In its annual statement the gross earnings of the company for the year are given as $448,067, and for its electric light plant $526,313, an increase of 36.43 per cent.

COLUMBUS, IND.—The City Council has granted a 50-year franchise to the Indiana Central Electric Railway Company, proposing to build a line from Columbus to Seymour and French Lick.

INDIANAPOLIS, IND.—The Wabash & Rochester Electric Railway, of Wabash, Ind., E. Spencer Pratt, secretary, has filed a mortgage for $900,000. The contract for the construction of the road has been awarded to United States Engineering & Construction Company, of Cleveland, Ohio.

HUTCHINSON, KAN.—The City Council has granted a twenty-year franchise to J. J. Burns, of Chicago, to construct and operate an electric railway in Hutchinson. Mr. Burns plans to purchase the Hutchinson Street Railroad, now being operated with horses.

BOSTON, MASS.—Representative John A. Coulthurst, of Boston, has introduced a bill into the Legislature which calls for the appointment of a special commission of five experts by the Governor to inquire into all public service corporations with a view of obtaining a franchise compensation and other results. The bill takes in all corporations like street railways, steam railroads, telephone and telegraph and gas and electric light companies.

DEERFIELD, MICH.—An effort is being made to obtain right-of-way from Briton through Deerfield for an electric railway, to connect with the Toledo line at Petersburg; a double track is to be laid and everything completed by summer.

BENTON HARBOR, MICH.—J. G. McMichael, of Chicago, has been given a franchise for an electric railway from Benton Harbor to Dowagiac, through Pipestone township. The road will touch all summer resorts along St. Joseph River. The only question now left unsettled is whether the road shall run from Eau Claire to Niles or from there directly to Dowagiac.

MINNEAPOLIS, MINN.—The County Commissioners have sold the old motor line right of way from Hopkins to Excelsior to the Minnesota Power and Trolley Company for $4,000.

ST. PAUL, MINN.—The City Council of South St. Paul has decided to make several amendments to a draft of a street railway franchise, which has been submitted to the council by the Twin City Rapid Transit Company.

GREENWOOD, MISS.—The Board of Trade has called a meeting of citizens to consider plans for building an electric railway from Greenwood to Belzona. This will serve a prosperous country not now reached by any kind of railways. It is proposed to handle both freight and passengers.

ELMIRA, N. Y.—Announcement is made that arrangements have been concluded for the building of a third rail electric railway between Elmira and Corning. The necessary application will be made to the State Railroad Commissioners at once. A private right of way has been secured.

NEW YORK, N. Y.—The Metropolitan Street Railway Company is considering a proposition made to it by Comptroller Grout that it operate cars on the Williamsburg Bridge, as a temporary measure of relief until such time as it will be possible to make arrangements for connecting the bridges on the Manhattan side. The suggestion is that the Metropolitan Company operate its cars on a loop around the Brooklyn terminal of the Williamsburg Bridge, thus obviating the necessity of a franchise in Brooklyn. There is plenty of room for such a loop in the Brooklyn terminal of the structure.

DEGRAFF, OHIO.—The Dayton & Kenton Electric Railway has let a contract to the Farnham Company, of Chicago, for the equipment of its projected line with the Farnham protected third rail. The officers of the electric railway company are: E. M. Hopkins, of New York, president; C. H. Pomeroy, of Saginaw, Mich., treasurer; W. E. Harris, of DeGraff, Ohio, secretary. The plan is to build lines from Dayton to DeGraff, New Carlisle to Springfield, DeGraff to Canton, and DeGraff to Bellefontaine.

NORFOLK, VA.—A company has been chartered here to build an electric railway to Elizabeth City, N. C. The distance is 40 miles. It is said that the Norfolk City Railway, which is owned by the Williams syndicate, of Richmond, is to build the road. General Manager Hathaway denies, however, that the company has any more interest in the charter than a traffic arrangement with the road when built.

BALLARD, WASH.—Surveys are being made in the interest of the Everett-Seattle Interurban Railway. It is understood that a franchise will be presented to the City Council at an early date, asking a right-of-way through the city.

MADISON, WIS.—The Outagamie Traction Company, of Appleton, Outagamie County, has been formed to build and operate an electric railway and power company, capital stock, $30,000; incorporators, Thomas Pearson, W. H. Holcomb, J. A. Hawes, John L. Jacquot and Paul V. Cary.

New Industrial Companies.

THE NATIONAL SWITCHBOARD COMPANY, of Jersey City, N. J., has been incorporated with a capital stock of $10,000 by Joseph F. McGrath, Gustavus A. Conover and George E. Groswold.

THE PITTSBURG AUTO-ELECTRIC COMPANY has been incorporated with a capital stock of $6000 by L. A. Ailes, Fred S. Ailes, R. S. Donaldson, E. W. McCormick and James F. Shepperson.

THE CRESCENT ELECTRIC COMPANY of Utica, N. Y., has elected officers as follows: President, J. C. Eichmeyer; vice-president, John Wenzel; secretary, W. P. Campbell; treasurer, A. J. Potter.

THE BOREAS ELECTRIC COMPANY has been incorporated at Washington, D. C., with a capital stock of $1,000,000. The incorporators are: Joseph Stretch, J. H. Lougborough, Jr., and J. Menick Freare.

THE CARBON MOTOR VEHICLE COMPANY has been incorporated in New York with a capital stock of $100,000. The directors are: C. A. Carbon, Brooklyn, and Leopold Soudheim and Eugene Soudheim, New York.

THE RICHARDS-RANDALL TELEGRAPH & TELEPHONE SUPPLY COMPANY of New York has been incorporated with a capital stock of $100,000. The directors are E. M. Jerome, F. M. Randall and G. C. R. Marshall.

THE ZINCOIL POLE COMPANY, of Texarkana, Ark., has been incorporated with a capital stock of $25,000 to conduct a general electrical supply business. The incorporators are John B. King, E. J. Spencer, D. C. Lingo and Charles M. Conway.

THE McKELVEY ELECTRIC COMPANY, of Youngstown, Ohio, has been incorporated with a capital stock of $10,000 to manufacture electrical appliances. The incorporators are: John Reed, Edward McKelvey, E. J. Anderson, F. W. Robinson, A. M. Wendlish and V. J. Laur.

THE CONDIT ELECTRICAL MANUFACTURING COMPANY has been organized at Augusta, Me., for the purpose of manufacturing electrical supplies. The capital stock is $200,000, of which nothing is paid in. The officers are I. L. Fairbanks, Augusta, president, and J. Berry, Augusta, treasurer.

THE BRADLEY RAILWAY SIGNAL & SUPPLY COMPANY, of Providence, R. I., has been incorporated with a capital stock of $100,000 for the purpose of manufacturing and dealing in electric railway block signal systems and electrical supplies in general. The incorporators are Harold E. Bradley, Warwick; Eugene F. Bowen, Providence, and Stephen A. Wood, Providence.

Legal.

WESTERN UNION-BELL ACCOUNTING.—At Boston, on February 3, Judge Colt in the United States Circuit Court ordered the American Bell Telephone Company to give an accounting to the Western Union Telegraph Company, the successful plaintiff in the recent royalty suit against the telephone company. Everett W. Burdett was appointed special master to take charge of the accounting and to hear all evidence that may be presented. The suit of the Western Union Company was to recover royalties from the American Bell Company under the well-known agreement, and the present action is concerning the amount of money to be paid over.

ELECTRIC LIGHT NOT A MANUFACTURE.—A case was settled recently in the Supreme Court of New Hampshire over a dispute arising in the village of Warren. Pub. St. 1901, c. 55, Sec. 11, provides that towns may, by vote, exempt from taxation for a term not exceeding 10 years any manufacturing establishment proposed to be erected or put in operation therein. It was held by the court on appeal that furnishing electric light and power, and distributing the same, was not manufacturing, within such statute, and such business not being separable from a vote exempting an establishment for manufacturing lumber, and furnishing steam and electric power, and distributing the same, from taxation, the entire exemption was void.

"CAR AHEAD" PRACTICE INVALID.—The Appellate Term of the New York Supreme Court—Justices Freedman, Gildersleeve and Greenbaum—rendered a decision last week upholding the ordinance which prohibits street surface railroad companies from compelling passengers to take a "car ahead," and imposes a penalty of $100 for each violation. Justice Gildersleeve wrote the opinion and both his colleagues concurred. It is held that the ordinance which in substance requires street surface railroad companies to carry a passenger "to any regular stopping place desired by him upon such car's route," without change of cars except for transfer to a connecting line going in another direction, or in case an accident renders compliance impossible, is valid and reasonable. Justice Greenbaum, in a concurring opinion which he wrote, went further and said that were it not for the ordinance passengers on street cars would be subjected to peril, traffic would be congested, and much inconvenience caused.

Obituary.

MR. J. L. KEBLER.—We regret to note that Mr. John Leonard Kebler, vice-president and general manager of the Ward Leonard Electric Company, died very suddenly, February 2, at Albuquerque, New Mexico, from an acute intestinal disorder. Mr. Kebler graduated in 1900 from Columbia University, taking the degree of electrical engineer. He was a member of the American Institute of Electrical Engineers and was widely known throughout the entire electrical fraternity. His untimely death comes as a great blow to his associates and to his uncle, Mr. H. Ward Leonard, with whom he has been living for the past 16 years. Mr. Leonard Kebler, his brother, has gone for the remains and will take them to Cincinnati for burial.

Personal.

MR. W. C. BURTON, of J. G. White & Company, Limited, of London, arrived in New York last week on a business trip round the world.

MR. H. H. STANLEY, of the Columbia Phonograph Company, has sailed for China. He will make his permanent headquarters at Shanghai.

MR. W. B. CHURCHER, and not Mr. W. Scheidel, was the author of the interesting paper on "Rectifiers," presented at the recent annual convention in Milwaukee of the Northwestern Electrical Association.

MR. A. M. HUNT, of the Engineering Offices, San Francisco, is visiting the principal eastern cities. He will return to the Coast via Vancouver, B. C., where his firm is superintending a large electric power installation.

MR. F. E. DRAKE, the well-known electrical manager, now president of the Lanyon Zinc Company, of St. Louis, has been visiting New York city the past week on business matters connected with that important smelting enterprise.

MR. H. F. STEPHENS has been elected general manager of the Central New York Telegraph & Telephone Company in place of Mr. Jeffries Wyman, resigned. Mr. Wyman retains the position as second vice-president of the company.

MR. RICHARD T. LAFFIN, formerly general manager of the Worcester, Mass., Consolidated Street Railway, who was recently appointed general manager of the Manila Electric Light & Railroad Corporation, has sailed for that part of the world.

MR. WM. MAVER, JR., announces that his new book, "Maver's Wireless Telegraphy, Theory and Practice," will be issued February 15, 1904. It will be a valuable treatise on the art, especially on the practical side, many details of which have heretofore lacked publicity.

MR. WILLIAM BARCLAY PARSONS, chief engineer of the subway, declares that if increase in the population of New York continues at its present rate, a new road with a carrying capacity as great as that of the completed subway will have to be built every four years.

MR. J. L. PUTNAM, general manager of the Clark Automatic Telephone Switchboard Company, Providence, R. I., has been laid up for a couple of weeks or more with inflammatory rheumatism, but we are glad to note that he is convalescing and expects to be on deck again soon.

MR. H. H. SINCLAIR, general manager of the Edison Electric Company, of Los Angeles, Cal., has left that city for a year's cruise through the South Sea Islands. He is accompanied by his family, on his boat, the "Lurline," the largest and fastest schooner-yacht on the Pacific Coast.

MR. H. HINE, formerly vice-president and general manager of the Stanley Electric & Manufacturing Company and now largely interested in the development of Mexican water power, being president of the Guanajuato Electric Light & Power Company, is again in New York at the Waldorf.

MR. G. F. METZGER, A. M. Inst. C. E., M. Inst. E. E., announces that having been appointed consulting engineer to the Manchester Corporation, England, for the completion of the work initiated by him as its city electrical engineer, he is now practicing as consultant in electrical and mechanical engineering at 3 York St., Manchester.

MR. JOHN H. KELMAN, for 14 years past prominently connected with the Stanley Electric Manufacturing Company at Pittsfield, Mass., and now superintendent, has resigned, and will at once, it is understood, join the electrical forces of the Allis-Chalmers Company, an important statement as to whose plans appears elsewhere in this issue.

MR. O. A. SANDBORGH has resigned his position as assistant electrical engineer with the Marine Engine & Machine Company, of Harrison, N. J., to accept an appointment with the Westinghouse Electric & Manufacturing Company at East Pittsburg, Pa., whither he has now proceeded from New York, where he has a wide circle of acquaintances.

MR. HERBERT W. SMITH, late of the Stuart-Howland Company, Boston, has associated himself with Mr. George H. Swazey under the firm corporate name of Swazey & Smith, with offices at 53 State St., Boston, and storeroom at Charlestown, Mass. They will furnish all material for lighting and railway plants and make contracts for complete equipments.

MR. REUBEN DUNELL, of D. H. Burnham & Company, the Chicago architectural engineers, has sailed for Europe for the purpose of creating a new department for J. G. White & Company, Limited, of London. The London concern intends to devote part of its attention to the construction of office and other buildings in the British metropolis and other parts of Great Britain.

MR. GEO. B. GORDON, of the Gramercy Exchange of the New York Telephone Company, has been appointed to an important position with the Chesapeake & Potomac Telephone Company, which controls the telephone system of Washington, D. C. Most of Mr. Gordon's time in his new position will be given over to supervising the installation of the common battery system, which the company is now adopting.

MR. CHAS. R. PRATT, who recently began independent practice as a consulting engineer, with offices at 160 Fifth Ave., New York, announces that he has associated with himself Mr. E. Van Winkle, a young engineer of considerable experience, who has been connected with the Otis Elevator Company, the Marine Engine & Machine Company and was lately the general manager of the National Coin Counting Machine Company.

MR. THOMAS J. JOHNSTON and Mr. George C. Dean have associated themselves for the practice of law with the firm name of Johnston & Dean, with offices at 11 Pine St., New York. Their specialties will be practice in the United States courts, particularly in equity; patent causes, proceedings in Admiralty, causes removed from State to Federal courts, customs cases, bankruptcy cases, etc. Both members of the firm have been admitted to the bar in many jurisdictions, and are well known practitioners.

MR. W. A. BIXBY.—This gentleman has become manager of the Quincy (Ill.) Gas and Electric Company. He has for some time past managed the lighting companies at Decatur, Ill. The capacity and output of the electric light plant there has been increased 25 per cent., and a heating plant has been built. Altogether in these three plants $200,000 has been invested in the four years. Mr. Bixby went into the lighting business at Nebraska City, Neb., in 1883. Since then he has held positions at Galena, Ill.; Little Rock, Ark.; Wichita, Kan.; Sherman, Tex.; Lorain, O.; Champaign and Decatur.

DR. G. F. KUNZ.—Dr. George F. Kunz, of New York city, special agent of the United States Geological Survey, has been appointed Commissioner of the radium exhibit at the St. Louis Exposition, and has been authorized to prepare and procure material therefor, comprising radio-active substances of all kinds, and also exhibits to illustrate the action of radium compounds, ultra-violet light, and Roentgen rays upon mineral and chemical substances. This exhibit is to be made by the United States Geological Survey in the United States Government Building at St. Louis. There will be a second exhibit of radium and radio-active substances in the Mines Building.

MR. CARLOS G. PALACIOS, the head of the electrical department of the Caracas Gas & Electric Light Company, Caracas, Venezuela, is now here for the purpose of investigating the latest equipment, purchasing same, and determining what shall be installed in several water power and steam-driven plants about to be constructed or added to in that South American country. Mr. Palacios some twenty years ago was connected with the old United States Electric Light Company. He was the first to introduce American electrical machinery into Venezuela, where he has installed numerous plants. He may be found at the offices at 79 and 81 Wall St. of Kates & Bok.

MR. JOHN McGEORGE, consulting engineer of the Wellman-Seaver-Morgan Company, has resigned, the change to take effect March 1. He has been connected with the Wellman interests as mechanical engineer for over 13 years. After March 1, he will be located at No. 501 Citizens Bldg., Cleveland, O., having opened an engineering office, under the name of McGeorge & Sons, taking into partnership with him his sons. He expects to do general consulting business, paying particular attention to power plants and the engineering side of office buildings. Mr. Ernest McGeorge, at present with the Wellman-Seaver-Morgan Company, will resign at the same time to become a member of the new firm.

MR. W. S. LAYCOCK, the large British contractor for railroad fittings, supplies, etc., who has introduced a number of American devices, including the Gold electric car-heating apparatus, for use on British, Colonial and Continental European railroads, is now on a visit to this side. He intends to make arrangements while here for electric car-lighting equipment for use on British steam roads. Mr. Laycock's plant, the Victoria Works, Millhouse, near Sheffield, is the only one on the other side which is completely equipped with Yankee machinery—Brown & Sharpe, Pratt & Whitney, etc.—and driven by electric power. It cost nearly $500,000. Mr. Laycock is accompanied by Mr. George A. Wyld, his chief engineer. They are guests at the Waldorf-Astoria.

MR. SAMUEL S. DICKENSON.—We are glad to note that Mr. Samuel S. Dickenson has been brought to New York city to assume the newly created position and office of general superintendent of the Commercial Cables. This well-known, estimable and highly competent electrical engineer has been connected with the Atlantic Cable service since 1874. He established and has been the superintendent of the Commercial Cable Company's important station at Hazel Hill, Canso, Nova Scotia, since 1884. His technical knowledge and capacity for practical affairs made him extremely valuable in his regular occupation, and marked him as a specially suitable official to employ on such vital work as the selection of landing places and the establishment of new stations whenever the company required services of that delicate nature. Thus he was sent by Mr. Ward to the Azores in 1900 to select a landing place and to create its station at Horta, Fayal, for the Canso-Fayal cable. This cable placed the Azores and North America in direct telegraphic communication for the first time; and for his services in connection with the event, the King of Portugal decorated him with a distinguished military order. When, in 1901, the Commercial Pacific Cables were planned, he was again sent by Mr. Mackay and Mr. Ward to select landing places at Honolulu, Midway, Guam and Manila. He also established the office at Honolulu. The new office which he has come to New York to direct was made necessary by the increasing amount of executive work growing out of the development of the company's business, and which his admirable qualifications make him eminently capable of filling.

Trade Notes.

WESTINGHOUSE BALTIMORE OFFICE.—The Baltimore office of the Westinghouse Electric & Manufacturing Company has opened temporary quarters at 221 North Calvert Street.

OBERG & BLUMBERG, contracting electrical engineers, have removed their offices in New York city from 853 Broadway to 112-114 West Forty-second St. and 107-117 West Forty-first St.

BULLOCK ELECTRIC MFG. CO., of Cincinnati, O., has issued very appropriately for its portrait calendar for February, one bearing the portrait and biography of Mr. T. A. Edison, whose birthday falls on the eleventh day of the month. He was born in 1847.

THE CHICAGO FUSE WIRE & MFG. CO., Chicago, New York and Buffalo, is drawing attention to a new line of switch outlet boxes which it is now prepared to furnish. Special attention is called to the fact tha this box is made to take any of the best makes of rectangular push-button switches and flush receptacles in common use.

THE EUREKA COMPANY, Chicago and Genoa, Ill., is now prepared to furnish its new Bell style self-restoring ring-down switchboard on which it has been favored with many orders recently. This drop has met with universal favor with telephone engineers, and is a new departure from the regular restoring drops. Its new bulletin on this new board is now ready and it would be pleased to forward same upon receipt of notice.

REMOVAL.—The American Conduit Manufacturing Company announces that its main office has been moved from New Kensington to Pittsburg, Pa. The better facilities for communication thus obtained will enable the company to render better service to its patrons than before. The company invites all interested in conduit work to call on it at its new quarters. New improvements completed at the New Kensington factory, the company states, has enhanced the superior qualities of American conduit. The new office address is 413 Grant St., Pittsburg.

THE CENTRAL ELECTRIC COMPANY is sending out a circular which quotes some very attractive prices on American Circular Loom flexible conduit, for which it is sales agent. The company especially requests that any one who is in the market for this class of material should write for quotations. Attention is also called to the fact that the Central Electric Company is sales agent for Edison primary batteries, formerly known as Edison-Lalande batteries. The company carries a complete stock of these batteries and is prepared at all times to make prompt delivery.

RAND DRILLS.—Contradicting the suggestion of a slackening of business activities comes the report that the "Imperial" pneumatic tool department of the Rand Drill Company telling of the large increase of sales since the first of the year. That the sterling worth of its products is universally appreciated is proven by the orders received for piston air drills, Wood boring machines and hammers and the installation of a number of complete pneumatic tool plants in the railroad shops, ship yards, boiler works, foundries and bridge and iron works, both in this and in foreign countries.

THE ALUMINO-THERMIC PROCESS.—The Goldschmidt Thermit Company has been formed as a corporation under the laws of the State of New York, for the purpose of exploiting in the United States of America the alumino-thermic process invented by Dr. Hans Goldschmidt and protected by United States patents. It is proposed to conduct business generally in connection with the Chemical and Tin Smelting Works of Th. Goldschmidt, Essen-Ruhr, Germany (founded 1847), and the company is prepared to handle all products dealt in by the parent concern. Offices have been secured at 41 Wall St., New York

THE EMERSON ELECTRIC MFG. CO, of St. Louis and New York, has just issued for 1904 a very handsome and striking catalogue of its fan motors, so well known all over the world. The cover is dark gray embossed in red, gold and black, and shows a standard fan motor in high relief on a wall bracket. The contents are more extensive and detailed than in previous years, and enter very fully into the construction and design of its various types for high and low-frequency work. The various fan motors are illustrated complete and sectionally, and the careful descriptive text is admirable. All told, there are 62 small square quarto pages in this compendium of the alternating fan motor art.

THE WARD LEONARD ELECTRIC COMPANY, Bronxville, N. Y., reports that it is enjoying great success in meeting the demands of the machine tool trade for controllers for use with variable speed motors, the speed variation being obtained by varying the field strength. The motor starter and field rheostat are so interlocked that the motor cannot be started under condition of weak field, and the fact that its field rheostats have a large number of points for control and its starter has an overload device which operates during the period of starting and the no-voltage release magnet is independent of the field strength, seem to have fulfilled the demands of the machine tool trade. It would be glad to cöoperate with any machine tool manufacturer in filling his demands.

LOCKE INSULATORS.—As has recently been exemplified and illustrated in this journal, a number of interesting new designs of high-grade insulators have been brought out and put on the market by the Locke Insulator Company, Victor, N. Y. We learn from Mr. Fred M. Locke, the president, that the company has lately considerably increased its facilities for handling small porcelain work, and desires acquaintance with the requirements of engineers and electrical manufacturers. Inasmuch as the Locke porcelain has been very highly developed for high voltage work, this should be of interest to all porcelain users. Its last publication, Booklet No. 7, is now being mailed, and will be sent on request to any one interested. The list of the large enterprises using these insulators is a long and convincing one.

OTTO WEISS MACHINE DEPARTMENT of the Chase Machine Co., of Cleveland, Ohio, writes us as follows through Mr. Thomas A. Aiton, manager: "We manufacture machinery used for forming electric wires and cables and for insulating the same. We manufacture a large range of these machines for all kinds of insulation from silk to lead. I worked from some four years in Berlin, Germany, as assistant to Mr. Otto Weiss, who was for many years the head engineer at Siemens Bros., London, and who manufactured and laid a great number of submarine cables. Later he established his own company in Berlin, for the manufacture of machines used in this line of work. Perhaps it would interest you to know that I have just placed a 4-head cabling machine with the Waclark Wire Co., at Bay Way, N. J. This machine is 96 inches long and weighs 55,000 pounds, and is used for making 61-wire strands up to two million circular mills. We have also placed several of these machines, as likewise similar ones though smaller, in many of the wire and cable works of this country."

PERFECT WINDOW LIGHTING.—Among the many methods of making a store-front attractive, well-lighted windows undoubtedly take first place. There can be no question as to what constitutes the best form of window lighting. The source of light must be hidden from view, yet the fullest illumination must be obtained from the lamps. This has become possible through the Frink system of lighting as embodied in the special patent window reflector of I. P. Frink, 551 Pearl St., New York. The reflector is composed of silvered corrugated glass set in a metal frame, designed on scientific lines so that all the light is reflected on the goods, yet is hidden from the sidewalk. Nothing is more annoying to an intending purchaser than to have his view of goods in a window blurred by the glare of electric lights. Progressive electricians are much interested in this subject and many have taken advantage of their opportunity by equipping the stores of their customers with Frink reflectors. A request to the above address will bring full information and estimate on the next store-lighting contract that any of our readers in the lighting field may have before them.

POOR'S MANUAL OF RAILROADS, recently issued, is considerably larger than any previous issue and correspondingly more complete in its scope and contents, returns of all leading railroads for the year ending June 30, 1903, or later, that were received up to Nov. 1, 1903, being included in its pages. Compared with the Manual for 1902, the current issue increased in the Department of Steam Railroads from 846 to 880 pages, the number of corporations for which statements are presented being 2,043 this year, against 1,937 in 1902. In the section devoted to statements of city and suburban railways, the number of corporations reported in 1903 is 1,177; in 1902, 1,156. The number of pages in this section is 257 in 1903, against 239 in 1902. In the department of miscellaneous industrial corporations, statements are presented for 236 enterprises against 199 in 1902. To provide space for this expansion in the scope of that department called for an increase of 32 pages, the Manual for 1903 devoting 145 pages to the presentation of statements of the affairs of "Industrials," against 113 pages in the previous issue of the book. It would be hard to find a more valuable statistical production than this as to financial investments and opportunities in the traction and industrial fields.

Record of Electrical Patents.

UNITED STATES PATENTS ISSUED FEBRUARY 2, 1904.

[Conducted by Wm. A. Rosenbaum, Patent Attorney, 140 Nassau St., New York.]

750,793. SELECTIVE SIGNALING SYSTEM; Garrison Babcock, Chicago, Ill. App. filed July 17, 1903. (See page 326.)

750,807. TELEGRAPH APPARATUS; John E. Carney, Montgomery, Ala. App. filed Feb. 24, 1903. A telegraph instrument comprising a permanent magnetic system having one of its poles divided into two pole pieces, and armature being pivoted on one of said pieces and free to play between the remaining two pieces; a winding modifies the action of the system.

750,811. OIL-SWITCH; William H. Cole, Watertown, Mass. App. filed April 29, 1903. The invention relates principally to a non-porous plug through which the conductors lead into the oil casing and which prevents escape of the oil along the conductors.

750,818. TROLLEY HARP OR FORK; Fred P. Crockett and Osro P. Johnson, Kalamazoo, Mich. App. filed April 4, 1903. Details.

750,825. AUTOMATIC TROLLEY LINE REEL; Charles F. Davy, Mohawk, N. Y. App. filed March 19, 1903. A spring drum and ratchet for retracting the trolley pole.

750,835. TELEPHONE-TRANSMITTER; Ernest B. Fahnestock, New York, N. Y. App. filed Dec. 2, 1901. (See page 325.)

750,845. SWITCHING APPARATUS; John S. Goldberg, Chicago, Ill. App. filed Nov. 26, 1902. Details of a ringing and listening key.

750,873. INSULATING SLEEVE AND METHOD OF MAKING SAME; Norman Marshall, Newton, Mass. App. filed June 6, 1902. A cylindrical insulating sleeve having its ends of different diameters and having a seam running its full length with abutting edges intimately shaped to each other.

750,876. ELECTRIC PLANT FOR CHARGING STORAGE BATTERIES; Joseph B. Meriam and Mark B. Crist, Cleveland, O. App. filed July 25, 1902. The plant consists of a gas engine, a dynamo adapted to be operated as a motor for starting the engine, a switch by which the motor is supplied with current from a battery temporarily for starting the engine and mechanism whereby the engine will drive the dynamo and be automatically stopped when the battery is fully charged.

750,894. ELECTRIC ARC LAMP; Joseph A. Rignon, Berlin, Germany. App. filed April 11, 1902. Two carbons are mounted upon corresponding arms of bell cranks, the other arms of which are connected with the core of the solenoid; the carbons converge and are brought together and separated by the solenoids.

750,938. ALTERNATING CURRENT WATTMETER; Charles A. Brown, Chicago, Ill. App. filed July 24, 1900. The windings of the meter, one for pressure and the other for current, are superposed, whereby the fields produced thereby are collocated.

750,939. PROCESS OF MEASURING WATTS IN ALTERNATING-CURRENT CIRCUITS; Charles A. Brown, Chicago, Ill. App. filed Nov. 19, 1900. The process consists in creating a single field by the current and pressure in the system and subjecting a measuring element to the action of said field.

750,940. ALTERNATING-CURRENT MOTOR; Charles A. Brown, Chicago, Ill. App. filed July 13, 1903. A combination between two energizing circuits serving to carry currents adapted to produce magnetic flux following the same path, and an armature carrying a short-circuited winding in inductive relation to said circuits.

750,947. ELECTRIC CONTROLLER; Frank E. Case, Schenectady, N. Y. App. filed Sept. 16, 1901. Relates to the arc-extinguishing and deflecting devices in a car controller.

750,948. DEMAND DISCOUNT METER; Frank P. Cox, Lynn, Mass. App. filed Aug. 15, 1902. Means for changing the speed of the meter so long as the line current exceeds a predetermined maximum.

750,953. PLUG-EJECTING JACK FOR TELEPHONE-SWITCHBOARDS; Robert G. Dunfee, Fostoria, Ohio. App. filed June 6, 1902. (See page 325.)

750,966. SURFACE-CONTACT ELECTRIC RAILWAY; John H. Guest, Brooklyn, N. Y. App. filed Feb. 26, 1903. Improvements in sectional conductor systems wherein an electro-magnet is first energized by a light current to close the circuit to a section and afterwards maintained in an energized condition by the power current.

750,971. SWITCH FOR SERIES ARC CIRCUITS; Caryl D. Haskins, Schenectady, N. Y. App. filed Aug. 22, 1902. A movable diamond-shaped contact device co-operating with spring contacts for the purpose of making the lamp connections before breaking the circuit connections, and *vice versa*.

750,972. MEANS FOR CONTROLLING ELECTRIC BOOSTERS; Edward M. Hewlett, Schenectady, N. Y. App. filed Aug. 31, 1900. A cut-out in the booster circuit is actuated automatically when the motor which drives the booster ceases to operate.

750,980. FIELD-COIL STRUCTURE; Charles H. Kaler, Schenectady, N. Y. App. filed Aug. 5, 1902. Ventilating spaces are provided in a coil by inserting blocks of wood between sections of the winding.

750,991. RAILROAD SIGNALING DEVICE; Joseph R. Marchesseault, Meriden, Conn. App. filed Nov. 13, 1902. Details.

750,993. ELECTRIC SWITCH; George Monson, Schenectady, N. Y. App. filed July 25, 1901. The blade is forked at the end and passes over the outside of two spring clips.

751,003. CONTROLLER CASING; Charles L. Perry, Schenectady, N. Y. App. filed Oct. 26, 1900. A latch for securing the cover of the controller casing.

751,012. FUSE BOX; Robert H. Read, Schenectady, N. Y. App. filed April 1, 1901. Venting channels communicate with the passage containing the fuse and terminate in metal mesh which relieves the escaping gases of heat.

751,013. SIGNAL DEVICE FOR SEARCH-LIGHT PROJECTORS; Robert H. Read, Schenectady, N. Y. App. filed Aug. 3, 1901. The casing surrounding the carbons swings on a center coincident with the axis of the carbon, for the purpose of covering and uncovering the light.

751,015. ELECTRICAL MEASURING INSTRUMENT; Lewis T. Robinson, Schenectady, N. Y. App. filed Feb. 10, 1902. The parts are so related that the magnetic return-piece or counter-torque element, in shifting from a position of maximum flux to a position of minimum flux, will cover an angle greater than 90°, resulting in an effective scale angle exceeding 60°.

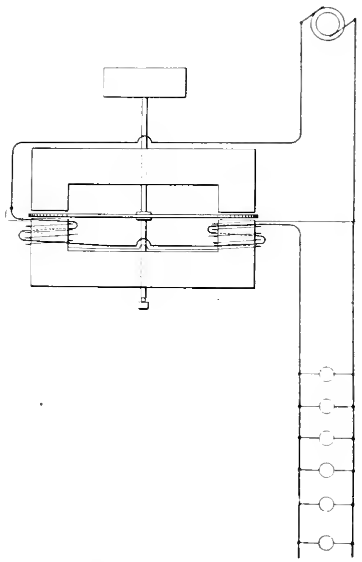
751,021. AUTOMATIC SIGNALING SYSTEM FOR ELECTRIC RAILWAYS; Harry B. Snell, Cement City, Mich. App. filed April 25, 1903. Details of a signal switch actuated by the trolley wheel.

751,025. ELECTRIC ARC LAMP; George E. Stevens and Walter C. Fish, Lynn, Mass. App. filed June 14, 1902. For the purposes of low cost and simplified construction the lamp is largely constructed of porcelain and punched metal fittings.

751,029. LAMP SOCKET; Julius C. Tournier, Schenectady, N. Y. App. filed April 30, 1900. Details.

751,046. PLATE FOR STORAGE BATTERIES; Joseph Bijur, New York, N. Y. App. filed March 31, 1902. (See Current News and Notes.)

751,048. SIGNAL SYSTEM FOR ELECTRIC RAILWAYS! Charles P. Breese, Norfolk, Va., and Adoniram J. Wilson, Westfield, N. J. App. filed May 5, 1902. Details.



750,939.—Process of Measuring Watts in Alternating-current Circuits.

751,071. SIGNALING APPARATUS; Edwin L. Grauel, Rochester, N. Y. App. filed March 19, 1903. Relates to the construction of make-and-break signaling apparatus for calling upon the relays of telegraph lines when it is desired to annunciate a rapid, steady and extended signal.

751,084. ELECTRIC SWITCH; Ernest A. Lowe, Plainfield, N. J. App. filed Jan. 17, 1902. A construction for obtaining strength in a switch blade which has mechanically attached to it and in the circuit an inclosed fuse.

751,100. ELECTROMAGNETIC ORE SEPARATOR; Ellen M. Oviatt and Alexander Dean, Denver, Colo. App. filed May 3, 1901. Details.

751,103. TELEPHONIC CALL INSTRUMENT; John D. Peachy, East Orange, N. J. App. filed Jan. 6, 1903. (See page 325.)

751,120. ELECTRICAL CONTROLLER AND BRAKE-OPERATING DEVICE; Walter W. Tice, Rahway, N. J. App. filed April 7, 1903. Details.

751,150. ELECTROMAGNETIC ORE SEPARATOR; Alexander Dean, Denver, Colo. App. filed Dec. 13, 1902. Wedge-shaped pole pieces overlapping each other, and over which the ore-carrying belts travel, are provided with adjustments for determining their relative position.

751,163. FEED WHEEL FOR AUTOMATIC TELEGRAPHIC PERFORATORS AND TRANSMITTERS; John Gell, London, England. App. filed March 17, 1903. The pins for drawing along the tape are carried by a sleeve which is slipped over the feed wheel and is adjustable to make the pins register accurately with the perforations in the tape.

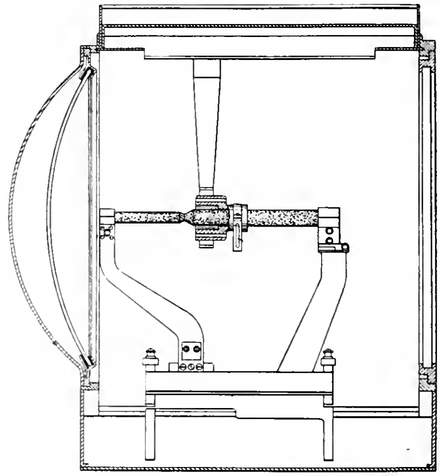
751,170. PROCESS OF ELECTROLYTICALLY PURIFYING JUICES. Alexander Knollrepp, Berlin, and Alfred Wohl, Charlottenburg, Germany. App. filed June 10, 1902. (See Current News and Notes.)

751,174. ELECTRIC SWITCH; William F. Irish, East Orange, N. J. App. filed July 23, 1902. Details.

751,175. THIRD RAIL FOR ELECTRIC RAILWAYS; Lloyd G. Johnstone, New York, N. Y. App. filed Oct. 10, 1903. The rail is covered by a metal plate supported on springs, and adapted to be forced downward by the shoe on the car to obtain the necessary contact.

751,191. ELECTRIC MOTOR; Hiram P. Maxim, Pittsburg, Pa. App. filed March 12, 1903. A motor frame comprising two cylinders and two end plates clamped together and completely inclosing the armature, the field-magnet pole pieces and coils and the commutator.

751,193. ELECTRICAL ALARM DEVICE; Burnett Menkin, Philadelphia, Pa. App. filed July 30, 1901. The invention comprises normally-open first and second circuits, in the latter of which the alarm is included, means for making and breaking the first circuit, a movable contact device for closing the second circuit and automatically breaking the first, and a switch for breaking the second circuit.



751,013.—Signal Device for Search-light Projectors.

751,227. ELECTRIC CUT-OUT; William H. Verner, Pittsburg, Pa. App. filed Aug. 28, 1902. Details.

751,228. CABLE HANGER; Richard H. Villard, New York, N. Y. App. filed Aug. 5, 1902. A strap with clamping-hook.

751,271. APPARATUS FOR HEATING AIR OR LIQUIDS TO A CONSTANT TEMPERATURE; Victor Eltz, Abbazia, Austria-Hungary. App. filed June 18, 1902. An expansible liquid automatic circuit controller.

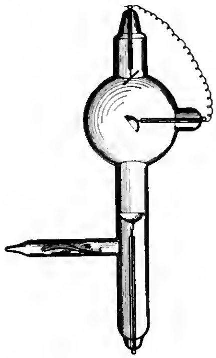
751,294. APPARATUS FOR ELECTRICALLY TRANSMITTING AND RECEIVING MESSAGES; Arthur T. M. Johnson, Highbury, England. App. filed June 6, 1902. A transmitting instrument having a secondary winding, and means for producing impulses therein at different rates, a number of receivers each operated by impulses of two different rates, one of which is common to all the receivers and the other specific to the particular receiver.

751,298. TROLLEY; John Kelly, Pittsburg, Pa. App. filed July 11, 1903. The lessening of pressure of the wheel on the wire throws up guard arms which prevent the wheel from actually leaving the wire.

751,304. ELECTRIC VACUUM DISCHARGE TUBE; Michel Krouchkoll, Paris, France. App. filed May 26, 1902. A bunch of glass fibre or capiliary tubes contained in the X-ray tube serves to retain a certain amount of gas by which the vacuum is regulated.

751,321. ELECTRIC LIGHT FIXTURE; John J. Miller, Pittsburg, Pa. App. filed May 21, 1903. Incandescent lamps are arranged upon a horizontal rail to be slid along the same to bring the light to the most advantageous position.

751,344. TELEPHONE-RECEIVER; Lewis Sands and Charles C. Cadden, Cleveland, Ohio. App. filed March 6, 1903. (See page 325.)



751,304.—Electric Vacuum Discharge Tube.

751,353. ELECTRIC BLANKET; Frank K. Singer, Wheeling, W. Va. App. filed Sept. 8, 1903. A heating resistance is distributed throughout the blanket.

751,354. INSULATED WIRING TACK; Donald G. Smart, Grand Rapids, Wis. App. filed Jan. 5, 1903. An insulating plate is adjusted under the T-head of a tack to prevent cross-connecting the two wires of the circuit that may be caught under the head of the tack.

751,362. THERMOSTAT; John L. Ward, Ord, Neb. App. filed July 9, 1903. An expanding rod moves an index finger over a scale until it touches a contact, when an alarm is sounded.

751,363. PRINTING TELEGRAPH RECEIVER; James D. White, London, England. App. filed June 19, 1903. Details.

Electrical World and Engineer

THE CONSOLIDATION OF "THE ELECTRICAL WORLD" AND "ELECTRICAL ENGINEER."

CONTENTS.

"THE BLUE RIBBON."

The annual dinner of the Institute last week was a much larger affair than expected and far larger than anything of the kind heretofore carried out under Institute auspices. A dinner to which nearly 500 people sat down, and with over 100 more as spectators is in itself quite a notable affair, but when it celebrates a particular anniversary and is attended by features of unique interest, it becomes memorable. The fact that the dinner signalized the twenty-fifth anniversary of the incandescent lamp and the founding of the first electrical medal of award in this country would in itself be enough to make it stand out conspicuously. It is, therefore, a matter of general congratulation that, according to universal testimony, the dinner was a success in proportion to its magnitude and significance. Those who saw the banquet hall of the Waldorf-Astoria certainly looked upon a remarkably brilliant spectacle, to which the presence of so many ladies contributed in no small measure.

The exercises of the occasion were also worthy of it, and the speeches full of excellent matter, which while not all of the light touch-and-go nature that makes for the laughter or cheering of the moment, stands better the test of time as an expression and record of the feeling of the hour. Mr. Insull, in turning over the Edison Medal and Deed of Gift to the Institute, struck a happy keynote when he characterized the medal as a "blue ribbon" of the profession that every young electrical engineer should be glad and proud to win. We believe the medal will not only help the young men, but will benefit the Institute in bringing it in even closer touch than now with the great body of coming members of the profession. The Edison Medal Association is, finally, to be congratulated on the ease and celerity with which it raised the proposed $7,000, a sum larger than that deemed necessary for the John Fritz Medal and adequate after all preliminary expenses have been met, for all the purposes embraced in its foundation.

THE BALTIMORE FIRE.

We are able to present in our pages this week some interesting data in regard to the Baltimore fire and its effect on the electrical services in that city. On the whole, it is a matter of congratulation that the telegraph and telephone services suffered so little and that such slight damage was inflicted on the lighting and street railway plants. It might have been a great deal worse, especially in view of the wholesale destruction of property, and this naturally brings us to a consideration of the lack of water supply and fire-fighting facilities in general. All reports from Baltimore go to show that the firemen did not have an adequate supply of water at any time. And yet an inexhaustible supply was at hand—"water everywhere, but not a drop to drink." If the firemen had only been able to avail themselves of the salt water all around the burning district they could doubtless have saved enough property to pay for the pumping plant many times over.

The same elements occur in considering the problem of fire extinction in New York City, and we are glad to note that Mayor McClellan has revived the plan to equip Manhattan Island, or at least its more valuable business sections, with salt water mains for fire purposes. These could be readily associated with electric motors for pumping the supply, and the project, if worked out on broad, adequate lines, should pay for itself several times over in higher insurance and lower rates for the districts covered.

In this connection we wish to emphasize what we have said before and is now our solemn duty to say again. The fire alarm system of New York is sadly and seriously behind the times. It is grossly inadequate. It needs practically entire renovation and reconstruction and the work cannot be taken in hand too soon. If Mayor McClellan will only secure a report from competent, disinterested experts he will find our statements justified and will realize that, with salt water mains or without, he cannot too soon overhaul the fire alarm system itself of this great western metropolis with all its incalculable wealth to be protected.

THE THEORY OF ALUMINUM ELECTROLYTIC RECTIFIER.

Within the last few years much interest has been displayed in the aluminum-carbon electrolytic cell, since experiments have been made looking towards making the apparatus industrially available as a rectifier. It is known that when a plate of aluminum is opposed to a plate of carbon in a suitable electrolyte, the cell so formed offers but little obstruction to an electric current entering at the carbon and leaving at the aluminum; that is to say, when the aluminum is the cathode. On the contrary, when the current is reversed and the aluminum is made the anode, the cell offers a very marked obstruction and practically shuts off the current, if the voltage does not exceed 20 or more volts. Consequently, when such a cell, or a battery of such cells, is inserted in the path of an alternating current, the semi-waves directed towards the aluminum go through with but little drop of pressure, or waste of power, while the intervening and oppositely directed semi-waves are automatically shut off, to a greater or less extent. In other words, the alternating current has become converted into what is substantially a unidirectional pulsating current. Such an arrangement could, of course, only utilize half the alternating-current impulses. But by the use of divided circuits or branches, with a pair of such batteries, all positive waves could be utilized unidirectionally in one branch, and all negative waves unidirectionally in the other, the two could coact, in most cases, to produce a unitary result, equivalent to complete rectification of the alternating current. The apparatus, however, has not yet come into practical use, mainly owing to relatively large losses of energy in the electric valves. That is to say, the current is not instantly shut off, as soon as the aluminum turns anode, but a certain amount has to go through, in order to shut off the rest, like the "wire-drawing" in an imperfectly adjusted steam valve. If this wire-drawing loss of power could be eliminated, the cell might be capable of some practical service on alternating-current circuits.

In the last number of the *Physical Review,* Mr. S. R. Cook contributes an article of some experiments made to elucidate the action of the aluminum rectifier. There is already quite a literature upon the subject, and various rival theories. The theories differ both as to the nature of the chemical action and also as to the nature of the electrical action. With reference to the electrical action, some contend that the opposition to the electric current, or the electric barrier, of the cell, is wholly, or substantially, a matter of ohmic resistance. They say that when aluminum is made the anode, the anions, either primary or secondary, are hydroxyl ions, which form an oxide or a hydrate film on the aluminum, and virtually coat it with an insulating paint. The high e.m.f. at the terminals of the cell under this condition they attribute entirely to IR drop of pressure in this high-resisting film. Others contend that the cell in the obstructive condition is the seat of a positive c.e.m.f., like the back e.m.f. of an electric motor at work. This difference of opinion resembles that which exists over the nature of the potential difference in the voltaic arc. In the latter case the phenomenon has been known for a longer time, and has formed the subject of more numerous investigations, so that the discussion has been more active and polemical. Some contend that the difference of potential at the voltaic arc is either wholly or substantially an IR drop of potential in ohmic resistance. Others contend for the existence of a true c.e.m.f. At the present time the advocates of resistance seem to have the best of the argument. The latest researches seem to indicate that of the fifty odd volts pressure at the arc, only a volt, or less, can be regarded as real c.e.m.f., like that of a voltaic cell, and the great remainder is due to the resistance of the carbon vapor column.

In the case of the aluminum cell, Mr. Cook seems to advocate the c.e.m.f. theory. Yet he admits that the film of material covering the aluminum anode—which he thinks is Al_2O_3—has a very high resistivity. Consequently, we have difficulty in precisely apprehending his conclusions. In the main, however, he regards the charged anions as being denied access to the aluminum anode by the superficial film of oxide. The negatively-charged anions are caught and arrested by this film, as torpedoes might be caught and kept from reaching the hull of a vessel by a torpedo-net. The layer of charged ions caught in the net constitute a layer which, according to the article, gives rise in some manner to a c.e.m.f. It seems reasonable, indeed, that the anions should be caught and massed together in this way; but the voltage of each anion cannot be more than about one volt, and the mechanism whereby the massing of such ions can build up a c.e.m.f. of some fifty volts is hard to realize. Moreover, if, as is admitted, the oxide film on the aluminum offers a high electrical resistance, then the passage of current through the film must produce a part, at least, of the observed potential difference.

During the steady flow of a unidirectional electric current through a conductor, it is usually impossible to tell whether the potential difference at the terminals of the conductor is due to resistance or to c.e.m.f. Take a thermo-electric junction, for example. If a current of one ampere determines a pressure of one-tenth of a volt at the terminals of the junction, there may be a thermo-electric c.e.m.f. of one-tenth of a volt and no resistance; or, there may be no c.e.m.f., but one-tenth of an ohm resistance; or, there may be partly c.e.m.f. and partly resistance. The power expended in the conductor by the current will be one-tenth of a watt on either hypothesis. The only hope of discerning which condition exists, during the continuance of the current, is to study the gradient of potential, and ascertain whether it be continuous or abrupt. If it be continuous, the inference is that resistance is involved. If it be abrupt, while the material is continuous, the inference is that c.e.m.f. is involved. In the case of the aluminum cell, the potential difference is developed in so short a distance that this test is hard to apply. When, however, the current is suddenly removed, there can be no residual c.e.m.f. if the effect is entirely due to resistance. On the other hand, if the effect be due to a real c.e.m.f. the latter generally persists to some extent after the removal of the impressed current. Thus, in the polarization cell, in the thermo-junction, in the magnetic circuit of hard steel, etc., the removal of the impressed current, or flux, leaves a clearly perceptible c.e.m.f. or c.m.m.f. In the case of the voltaic arc, no appreciable residual c.e.m.f. has yet been detected. The article mentions that when the current polarizing the aluminum-anode cell is suddenly interrupted, there appears to be a distinct and powerful residual c.e.m.f. If this exists in a circuit of negligible inductances, then this is indeed evidence of a real c.e.m.f. But apart from this, the remainder of the evidences cited in the article do not seem to us at all conclusive. The subject should receive further investigation.

Alternating Current Railway Motors.

We count ourselves fortunate having been able to present to our readers in our issue of last week so interesting a discussion as that in which Messrs. Lamme and Steinmetz played the principal rôles at the last Institute meeting. It not infrequently happens that during the progress of a discussion many important matters which have been—well, let us say secluded—in the papers themselves, find the light of day, and in this instance the tail certainly wagged the dog. The game opened with a very lucid and pertinent discussion by Mr. Lamme of the whole question of single-phase railway motors, including particularly a comparison between the series and the repulsion types, with respect to their design and properties. On the whole, Mr. Lamme's remarks were the most illuminating which we have yet heard regarding the new railway motors, and we commend them heartily to the careful attention of those interested in the subject. We do not altogether agree with the speaker's classification of the commutating single-phase motors. It seems to us that a sharp line should be drawn between the pure series-wound motor in which the currents delivered to field and armature flow in one and the same circuit and are dynamically in the same phase, and those in which the phase difference between the currents in armature and field is part of the organic theory of the motor. The pure series type to which Mr. Lamme has adhered is in principle and theory on all fours with the series-wound, direct-current motor. The latter, as is well known, does not reverse by reversal of the current at its terminals, but only when the reversal is as between armature and field. If such a machine is fed with an alternating current at one cycle per second, the same relation holds true, and so on up to the point where, with increasing frequency inductance and parasitic currents, block the game.

Mr. Lamme's work has been to plan the structural features of the motor so as to permit the frequency to be carried up to a figure within the range of commercial alternating practice, and so far as has transpired he has done a very workmanlike job. As he explains in the discussion, he has cut down the serious inductance of the field by making it very weak compared with the armature and by working at low saturation. He has provided a very powerful armature, thus throwing the main work upon the element of which the inductance is less serious, and, as we learn from his English patent, he has perforated the salient poles longtitudinally to lessen the otherwise great cross-magnetizing effect of the powerful armature. He has employed resistance in the commutator leads to diminish the effect of the coils short-circuited in commutation and has, in short, used to good advantage all the arts of the skilled designer. And he states in the most unequivocal manner, that the result has been to eliminate sparking as a practical difficulty. On the other hand, the motors developed by Winter and Eichberg and by Dr. Steinmetz belong squarely in the category of alternating-current machines. They deal with field magnetizations and currents displaced in phase and brought into harmony by establishing a fixed polar line in the armature through the agency of the commutator. They may be treated in theory as motors having rotary fields, although as we intimated in our notice of Dr. Steinmetz's paper, this treatment is not necessary any more than it is in the case of a pure induction motor. The repulsion motor invented by Prof. Thomson is one of the most ingenious and interesting of the alternating class and possesses many of the most valuable properties of a pure series motor. In fact, the series characteristics making it essentially a motor for vairable speed undoubtedly stood in the way of its progress when it was invented, the demand then being for motors of inherently constant speed. Now, freed by the progress of the art, like the series motor, from the incubus of high frequency, it has been developed into a machine of great and immediate value.

As regards the relative merits of the two types, it is too early to speak from experience. Each type must in practice transform down for the armature the voltage of the trolley wire. The series motor does this by a separate transformer, the repulsion motor by transformation in the motor. As between the two processes we are not inclined to think that there will prove to be any material difference either as regards efficiency or power factor. The losses will be distributed somewhat differently in the two. As Dr. Steinmetz pointed out, the repulsion motor will utilize less iron and more copper and works its iron at higher density than the series motor. Up to the maximum voltage for which the fields of the repulsion motor can be wound, we should think it would have a material advantage in total weight of equipment over the series motor. At higher voltages than this it would lose such advantage. Both types can be used on direct currents, the series motor perhaps the more readily of the two, being the less separated in design from a direct-current motor. Both can return energy to the line by way of braking and the series motor can be, if need be, "slugged" like a direct-current motor. Both suffer from a poor power factor at starting, poor even compared with standard polyphase motors, against which low power factor is often discharged; but as Mr. Lamme pointed out, the actual volt-amperes taken in starting are not excessive owing to the efficient means of control available with alternating currents. The speed-torque curves of the two types are much alike, not differing more than would two motors of the same type but of different design, and when at or near normal speed the power factors are amply high in spite of a liberal air-gap, much larger than is usual in the polyphase motors.

As regards the practical working properties of these two types of motor, it is too early to speak with much certainty. Both Mr. Lamme and Dr. Steinmetz agreed that little can be told regarding the relative excellence of series and repulsion motors by experiments on one line of machines operated in both ways, for the fundamental elements of correct design differ in the two cases. Moreover, the game is as yet young and in a matter which depends almost entirely upon the *virtuosity*—to steal a word from Pharisees—of the respective designers, one could only guess at final results. It seems to be agreed that the sparking problem has been solved, within limits at least, and that in general operative properties the new motors will have most of the virtues of the ordinary ones, in addition to some peculiarly their own. Present indications are that the alternating motors will be materially heavier than the present standard railway motors, and also by a few per cent. less efficient. We have little doubt that further experience will relieve one or the other of these conditions, but hardly both unless at great additional cost of construction. However, as we have repeatedly stated, the efficiency of the worst of the newcomers compares favorably with the efficiency of the best direct-current railway motor with a rotary converter tied to its tail. Also, the small increase in weight of motor may be considered as merely of an academic interest, since the proportion of dead weight to live weight in any motor car is large and varies far more from one type of car body to another, than in virtue of a change in motors. Nobody protests at a few hundred pounds extra weight in a new and elegant car body. As for the motors, time will tell.

Telegraphic Work in Baltimore During the Fire.

The experiences of the telegraph companies during the great Baltimore fire last week were quite thrilling, and we believe that many of our readers will be interested in the narrative given below of the ordeal undergone by the staff of the Postal Telegraph-Cable Company. Elsewhere in this issue are some other data regarding the more fortunate escape from destruction of the light and power plant of the United Electric Light & Power Company.

The main office of the Postal Telegraph-Cable Company at Baltimore was located on the twelfth floor of the steel skyscraper of the Continental Trust Building on the corner of Baltimore and Calvert Streets. A large force was on duty during the conflagration and when it became evident, about 7 P.M., that there was danger of the destruction of the building all wires north and south were connected through in the subway terminal room in the basement. The records and some apparatus were hurriedly moved to a branch office about half a mile from the main office and other apparatus was packed and taken to the ground floor ready for removal.

At 9.15 P.M. the Continental Trust Building caught fire, burning rapidly, and the operators were compelled to leave, barely having time to get out. The rain of fire in the streets was so intense that Superintendent Lemon, Manager Moore and Cashier White, the last ones to leave the building, had to run for their lives, abandoning the instruments that had been carried as far as the door step. The force then groped their way to the branch office, being drenched to the skin by a bursted hose en route, only to find that that office was also on fire and that the records and apparatus previously removed from the main office had been consumed. The terminal poles where the underground cables meet the aerial lines in the northern and southern sections of the city were then visited, temporary quarters were secured near them, and offices opened for business. These offices were in operation before midnight, one of them being in a Hebrew sweatshop amid surroundings that were far from agreeable.

The executive department in New York was apprised of the conditions and the first morning train leaving New York for Baltimore carried the Postal's portable quadruplex telegraph plant, consisting of an engine, dynamos, switchboard, motor transformers and quadruplexes arranged in cases in such a manner that they may be placed in operation in a few minutes after arrival at destination. Superintendent Lemon had secured new headquarters for the company at 219 North Calvert Street early on Monday morning and immediately begun stringing wires to that point, but unfortunately was short of instruments with which to work them, all spare apparatus and instruments, despite the efforts to save them, having been lost in the fire which burned both main and branch offices.

The portable multiplex plant and an ample quantity of spare instruments shipped from New York reached Baltimore about noon, but owing to the difficulty of obtaining trucks it was impossible to get them delivered until about half-past 5 P.M. A half hour later a full outfit of quadruplexes was in operation. By the following (Tuesday) morning the operating force of the company had been consolidated at the new office, a commissary department had been established, furnishing all employees with coffee and food, connections had been made from the underground system to the new office, and all wires cut into the switchboards there.

The wires cut through in the terminal room in the Continental Trust Building remained in working order between New York and Washington until about 3 o'clock on Monday morning, when they failed. An examination made by Mr. Skirrow, assistant electrical engineer of the company, on Tuesday morning, as soon as it was possible to get at the terminal room in the heated ruins, showed that the iron terminal frames had stood intact, but that the insulation and lead covering on all wires and cables in the room had been entirely consumed. He immediately restored the connections, although parts of the basement were then burning and continued to burn until Tuesday evening.

In addition to the regular force in Baltimore, Superintendent L. Lemon, of Philadelphia, was on the ground from 2 o'clock on Sunday; Superintendent of Construction W. H. McCollum, with several men, arrived early Monday morning, and Mr. Skirrow, with J. F. Needham and several assistants in charge of the emergency apparatus, arrived Monday noon. Mr. T. E. Fleming, special agent, went from New York to Baltimore on Tuesday and assisted in the permanent reorganization of the delivery and accounting departments.

The efforts made and the work done by the entire force elicited the highest commendation. Everyone forgot himself and worked with might and main to re-establish the service. Although nearly every employee suffered some personal loss, operators losing their typewriters and messengers losing their bicycles, etc., not a word of complaint was heard and, despite cold and hunger, every man and boy worked all day and all night and again the next night without rest until the service was fully restored.

So far as transmission on the wires was concerned, the traffic was handled with comparatively little delay even on Monday, but the company experienced very great difficulty in delivering the business, it being almost impossible under the conditions prevailing for messengers to find addresses. The local post-office, however, had escaped and the post-office people were sorting mail matter promptly and business houses were calling at the general delivery windows for their mail. The Postal Telegraph Company, therefore, immediately dropped into the post-office and telegrams which could not be promptly delivered by messenger and in this manner effected deliveries of telegrams as expeditiously as possible under the circumstances.

In the meantime, the regular messenger delivery service was rapidly being re-established by means of a card index on which new and temporary addresses were systematically entered as quickly as they could be collected. The regular deliveries were still further expedited by the use of a special "outlook" envelope, the front of which was partly composed of translucent paper, so that the address of the original message could be read through the envelope, thus obviating the necessity for addressing it.

The prompt and efficient restoration of the telegraph service did more than any other one thing to assist in bringing order out of chaos and in allaying the apprehensions of business houses throughout the country by making it possible for them to communicate promptly with their Baltimore correspondents and thus learn the status of their business affairs. Notwithstanding the fact that the volume of commercial and press business handled during the three or four days succeeding the fire was very largely in excess of the normal business, it was handled with remarkable promptness.

The Pratt Street Power House in the Baltimore Fire.

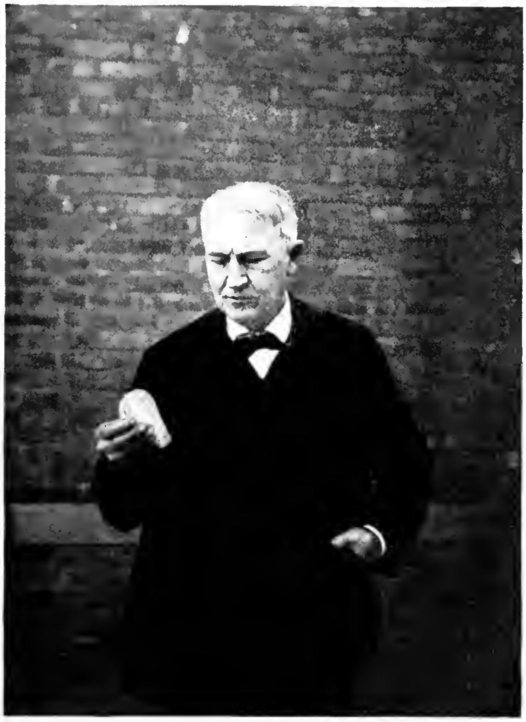
One of the remarkable features of the great Baltimore fire was the saving of the Pratt Street power house of the United Railways & Electric Company, with all of its valuable electrical machinery, although the building was in the midst of the conflagration. The saving of the house and its contents was a piece of great good luck for the whole city, as well as for the company that owned it, as it permitted of the starting up of the street railway service within 24 hours after the fire was under control and a resumption of service which otherwise might have been delayed for weeks.

The power house consisted of three sections, the first section being the old power house, in which was installed direct-current apparatus; the second section is the boiler room, and the third section is the new plant, in which is installed four Westinghouse 2,000-kw, 132,000-volt, three-phase, fly-wheel type, alternating-current generators. The bus-bar structure is in the basement and over this are installed the oil switches, three for each generator and three for each feeder. The control of these switches is in a gallery built at the end of the generator room.

The old part of the power house was destroyed, and in the new part, where the new generators are located, the basement was flooded with water nearly up to the bottom high-tension bus-bar. The building in which this machinery was installed, however, is absolutely fireproof, the window casings and frames being of copper and the glass provided with wire netting. While the flames raged all around, the building did not suffer and in fact a cat which was in this power house came through alive. The old power house burned early Monday morning; by Tuesday afternoon at 5 o'clock the water had been removed from the basement of the new section, test had been made of the Westinghouse apparatus, and the result was that the machines were placed in operation at this hour and started in to furnish current to the sub-stations, and have been running ever since without difficulty.

Annual Dinner of the American Institute of Electrical Engineers.

THE annual dinner of the American Institute of Electrical Engineers, held Thursday, February 11, at the Waldorf-Astoria, was an event of unusual importance in Institute annals and in electrical history in America. It celebrated the twenty-fifth anniversary of the practical perfection and commercial introduction of the incandescent lamp, and the dinner occurring at an opportune season of the year was associated also with Mr. Edison's birthday. A few months prior to the affair, the Edison Medal Association was formed to found a medal in the Institute which would signalize this anniversary in electric lighting development, and at an early stage it made arrangements with the Institute dinner committee so that the dinner might be devoted more particularly to the celebration of the anniversary. If the reports of the daily press are to be taken as any criterion, the affair was one of the most notable of the kind celebrated in recent years in this city, the New York *Herald*, for example, speaking of it as a banquet that for novel effects in decorations, ingenious souvenirs and noteworthy messages of congratulation probably was never eclipsed. The Institute dinner committee comprised Messrs. Calvin W. Rice, chairman; Arthur Williams, T. C. Martin, Charles W. Price, E. H. Mullin, Calvert Townley, F. C. Bates, Bancroft Gherardi, Jr., and W. J. Hammer, with whom were associated Messrs. R. R. Bowker and Frank J. Sprague on behalf of the Edison Medal Association. The officers of the Medal Association contributing actively also with its executive committee to the success of the event were Messrs. Samuel Insull, chairman; Charles Batchelor, vice-chairman; Frank S. Hastings, treasurer; R. T. E. Lozier, secretary.



THE MAN AND THE LAMP.

The banquet was given in the grand ballroom of the Waldorf-Astoria at 7.30 and was preceded by a reception to Mr. Edison at 6.30, when he received the congratulations of the guests assembled, numbering not far short of 500, and including well-known and distinguished people in scientific, artistic, technical, literary, financial and commercial circles. The ballroom was most elaborately decorated for the occasion under the direction of Mr. Arthur Williams, and has never looked so well. In addition to the regular incandescent lighting, the tiers of boxes were all elaborately festooned with Elblight cable and lamps entwined with smilax, and incandescent lamps also adorned the speakers' table in long festoons. Back of the speakers' table were draped American flags and a pyramidal arrangement of 57 incandescent lamps, and in the middle was a handsome oil painting, loaned by Mr. W. J. Hammer, of the modest little house at Milan, Ohio, where Mr. Edison was born, in 1847. Above it was the shield of the State of Ohio and on the two sides were the shields of New Jersey and New York, as being those States most prominently identified with his inventions and work. The menu prepared for the occasion was a sumptuous piece of work, being vellum quarto of 12 pages and cover printed in blue and gold, and containing a portrait in color by the Ives process made from a well-known bust of Edison. This Mr. Edison had been good enough, at the request of the dinner committee, to autograph in advance, so that every guest carried away a memorial which of itself was valuable and interesting as a souvenir of the occasion. The "end covers" of the menu were elaborately worked out in gold, with the initials of the Institute and of Mr. Edison encircling magnets and incandescent lamps; and the same motif was reproduced as a border for each page. The menu included also two sextets written for the occasion by Mr. R. R. Bowker, which are quoted below, one novelty in connection with them being the fact that they were not written out but were dictated directly to the phonograph.

The dinner committee had also prepared a number of other interesting conceits and surprises which added greatly to the charm and interest of the occasion. The stick pins for the boutonnieres were little incandescent lamps furnished by the General Electric Company. The cover of the sorbet box was a large reproduction in old ivory celluloid of the statue of the Genius of Light made by the Italian sculptor, Bordiga, and now one of the prominent features of the library at the Edison Laboratory. The ices were molded in the form of incandescent lamps and were brought in in a procession by some 40 or 50 waiters, each of whom carried a large pastry model of some electrical device or invention, including huge reproductions of the early Edison dynamo, the Edison phonograph, a multipolar machine, resistance boxes, electric automobiles, badges of the Institute and other effects. All these and sundry other details were received with great enthusiasm by the occupants of the ballroom who, it may be noted, included 150 ladies, most of whom were in full evening dress. The rostrum, or speakers' table, was occupied by President B. J. Arnold, having Mr. Edison on his right as the guest of honor; Prof. Elihu Thomson, Prof. C. F. Brackett, Dr. A. E. Kennelly, President C. A. Coffin, of the General Electric Company; President Ambrose Swasey, of the American Society of Mechanical Engineers; Mr. John Fritz, Mr. Samuel Insull, president of the Edison Medal Association; Mr. C. L. Edgar, president of the National Electric Light Association; Mr. Joseph B. McCall, president of the Association of Edison Illuminating Companies; Mr. W. H. Fletcher, president of the Engineers' Club; Col. R. C. Clowry, president of the Western Union Telegraph Company; Mr. A. B. Chandler, president of the Postal Telegraph-Cable Company; Mr. George G. Ward, president of the Commercial Cable Company; Mr. W. J. Wilgus, vice-president New York Central Railroad; Mr. J. J. Carty, president of the New York Electrical Society; Mr. C. F. Scott, chairman of the Union Engineering Building Committee of Fifteen; Mr. R. W. Pope, secretary of the Institute, and Mr. T. C. Martin, toastmaster.

After the service of the dinner President Arnold called the company to order and read the following message from President Roosevelt:

THOMAS A. EDISON, Waldorf-Astoria, New York:
I congratulate you as one of the Americans to whom America owes much; as one of the men whose life work has tended to give America no small portion of its present position in the international world.

The reading of this dispatch was received with great applause and a standing toast was drunk to the health of the President of the United States. Mr. Arnold then delivered an interesting speech on the Institute and its relation to the affair of the evening, in the course of which he said:

We have met on this, the day of our annual feast, not only to renew the friendships incidental to those engaged in a common cause, but to assume an obligation which, if administered faithfully by us and our successors, shall tend to stimulate the ambition of many of our student class and bring to some of them that intangible something called success. If you ask me what is success, I cannot answer; but those whose ambition is to add to the sum of human knowledge or accomplish something for the material advancement of the race, need no answer.

It is to this class of young and ambitious men that our attention is directed to-night. If, in the future, they need inspiration, let them recall this occasion and remember that around these tables sat men who were the exponents and active agents of one of the greatest forces in nature, and that through their achievements in mastering this silent force, there was effected in a brief period of but little over twenty years one of the greatest advancements in material wealth and scientific knowledge in the history of the world.

Either around these tables sit, or associated with us in similar societies across the waters are the men, who, through their efforts have converted our cities from darkness into day, increased the range of human speech, bridged our oceans for the transmission of intelligence, with and without wires, made it possible to preserve the human voice long after the speaker has passed away, emancipated the horse, and who bid fair to continue to eliminate the element of distance in the transmission of electrical energy until the steam locomotive, formidable rival that it is, shall have been emancipated to its final extinction.

It is especially fortunate that our profession is so young that we can select for our first distinction the one whom we all agree is now the most deserving and instead of honoring him after he has passed beyond the appreciation of earthly honors, we are able to have him with us to-night, to see and to feel the esteem in which he is held by his protégés, who recognize in him not only a man of great natural genius, but also the exemplification of what has been defined as genius itself, "the ability for hard work." Therefore, as the dean of the greatest technical school of the world through which the graduates of all other schools must pass, the school of practical experience, and in which school he has eclipsed us all in individual achievement in those arts which tend for the material benefits of his race, do we recognize him and by these ceremonies honor ourselves in thus honoring and officially perpetuating the name of Thomas Alva Edison.

At the close of his remarks Mr. Arnold introduced Mr. Martin as toastmaster, who, in proposing the health of the guest of honor, said:

The American Institute of Electrical Engineers is proud to embrace in its membership to-day the foremost inventors of the age and the greatest captains of industry, and has placed upon its golden tablets many an auspicious discovery and art to celebrate. But it surely could find no worthier hero among them and no better gift to mankind to signalize than the man and the lamp around both of whom we twine to-night the laurel wreaths of our admiration and our love.

There should be encouragement in the founding of this medal tonight for every struggling, ambitious youth in America. Let us and let our sons recall and applaud the cheery little newsboy at Detroit; the half-shod, half-frozen operator seeking bravely a job along the icy pikes of the Central States; the gaunt, untutored experimenter in Boston, taking eagerly needed fees for lectures he was too modest to deliver; the embryonic inventor in New York, grubstaked by a famous Wall Street man for his first stock ticker; the deaf investigator at Menlo Park who wreaked unique retaliation on his affliction by preserving human speech forever with his phonograph; the prolific patentee who kept the pathway to the Patent Office hot with his footsteps for nearly forty years; the genius, our comrade, who took this little crystal bulb in his Promethean hand and with it helped to give to the world a glorious new light which never was before on land or sea—Thomas Alva Edison.

Mr. Edison had declined to make a speech of acknowledgment, but had consented to wire his response, and to carry out this purpose the Western Union Telegraph Company had furnished for the evening an Edison quadruplex set with an extension key, so that Mr. Edison could send his message without leaving his place. The message was received at one end of the speakers' table on a portable Postal quad set by Mr. A. B. Chandler, who, a great many years ago, gave Mr. Edison his first official position by making him electrician of the old Atlantic & Pacific Telegraph Company. The wires were carried above the table on a regular pole line. The message was transmitted at the same time over a wireless telegraph system between the table and the other end of the banqueting room, installed by the Marconi Company. Mr. Edison's reply was as follows:

I want to thank first of all my fellow-members of the American Institute of Electrical Engineers for the great honor done me in thus celebrating my birthday, associated with the twenty-fifth anniversary of the completed development and successful introduction of the incandescent lamp. Your expressions of good will gratify me deeply. While I cannot but rejoice at the place which the incandescent lighting art has made for itself among the inestimable comforts and conveniences of civilization, I feel that my share in the work is exaggerated by this prominence given me to-night.

To my old friends and associates who have founded the Edison Medal in the Institute—I can but extend you thanks again. If I could do it in return, I would found a medal for every one of you, for you are just as much entitled to recognition as I am. You gave me your friendship and loyalty, your watchful days of toil and sleepless nights of anxiety. Some of you helped to perfect the art by your engineering skill, your legal ability, your financial aid.

The early days were enough to tire our any one's courage and persistence, but you stood it all, and put up with me into the bargain. Now, in noble revenge for the burdens I put on you, and in addition to all the evidences of friendship in the past, you add this unusual token of continued affection. I should not be human if I were not profoundly affected and deeply grateful.

This medal is founded to encourage young men to devote their best thought and work to electrical development. I rejoice in this stimulus to harder study. Better trained and educated than were we pioneers of the times before every college and university had its electrical course, these coming men of the future should, and I believe will, carry forward to triumphs and arts heretofore undreamed of, the principles and applications of electricity to which I have tried humbly to devote my life and energies from the hour my hand first touched the key. God bless them, and you, my dear friends, and this American Institute of Electrical Engineers.

While the message was being sent the toastmaster read selections from a number of congratulatory messages, cablegrams and telegrams received, including the following:

Hearty congratulations birthday; sorry not present celebrate 25th anniversary your great invention. MARCONI.

It is most unfortunate that I cannot be present when the "King of the Telegraphers" is to be crowned with the Medal Crown. Though absent, yet I here profess to the monarch loyal and unfaltering allegiance, swearing to render him at any and all times such service as the most potent head of the clan that ever ruled his people, ever received from his humble and devoted subjects.

To which I hereby pledge our life, our fortune and our sacred honor. Long life "King Edison the First." ANDREW CARNEGIE,
Liegeman to King Edison the First.

"73" to one and all.

Ohio claims a large share in the glory of Mr. Edison's career by reason of the good start she gave him. The people of Ohio are deeply interested in his great achievements and rejoice over the fame he has won.

Speaking as the representative of Ohio, and for myself, I join you in felicitations to the guest of honor, and extend to him my best wishes for many years more of usefulness.

MYRON T. HERRICK,
Governor of Ohio.

Will you be kind enough to extend to Mr. Edison my sincere congratulations upon his fifty-seventh birthday? It is hard to realize that so many wonderful achievements could be crowded into the brief space of years since Mr. Edison arrived at manhood. It is still more difficult to appreciate the full effect of his inventions; what they mean to the civilized world in added comfort, economies, in expediting business and in bringing the whole world in closer communication.

With the friends who will surround him on this occasion I beg to join in extending best wishes for many years of usefulness and honor. BENJAMIN B. ODELL, JR.,
Governor of New York.

I am glad to know that the American Institute of Electrical Engineers propose to do special honor at their annual dinner to Mr. Thomas A. Edison, a distinguished citizen of New Jersey, whose remarkable achievements have been an honor to his State and country and of the highest usefulness to mankind.

Few men in history have found so wide a range for their inventive genius, and perhaps no one has contributed more by his inventions to make life safer, or more enjoyable or happier than he. New Jersey is proud of him, not alone for his wonderful achievements, but for those sterling qualities of manhood that make his life a model and an inspiration to all. FRANKLIN MURPHY,
Governor of New Jersey.

From President Francis, of St. Louis Fair.

Extend my warmest felicitations to Mr. Edison and assembled guests. I wish to express my admiration for the genius of mind and craft of hand that have accomplished so much in a quarter of a century, and I hope the presentation of electricity at the coming universal exposition will fittingly evidence these great achievements. The Exposition is honored in having Thomas Alva Edison high on the roll of its honorary chiefs. D. R. FRANCIS.

From Lord Alverstone, Lord Chief Justice of England.

Hearty good wishes to Mr. Edison. I look back with greatest interest to his brilliant inventions in electric lighting and telephony, which I had the great pleasure of successfully maintaining in all the courts in England.

From Lord Kelvin.

I join heartily with the American Institute of Electrical Engineers in gratitude to Edison for his great electric work and for the phonograph, a most exquisite and instructive scientific discovery, and for his many other useful and well-worked-out inventions for the public good.

From Prof. Colombo, Italy.
I enthusiastically join in the honors paid to-day to my dear and illustrious friend Edison, whose system I am proud to have introduced first into Italy.

From E. De Fodor.
Admiring your great inventions, Hungarian friends send sincerest congratulations.

From Paris.
The electricians of France send their heartiest congratulations to Mr. Edison on the occasion of the ovation in his honor. Mascart.

From Berlin.
Greeting and kind wishes to American engineers. Congratulations to Edison on the twenty-fifth anniversary of his inventing the glow lamp. Gisbert Kapp.

Hearty congratulations to our honorary member of the Elektrotechnischer Verein. Emil Naglo.

From the Italian Society of Electrical Engineers.
Honor to your illustrious guest. Fraternal greetings to the American Institute of Electrical Engineers. Ascoli.

Other messages were received from Mayor McClellan; the president of the English Institution of Electrical Engineers; Francis Jehl, Joseph Wetzler, G. A. Hamilton, C. P. Bruch, etc. It is needless to say that Mr. Edison's health, his response and the messages were all received with immense applause and enthusiasm.

The toastmaster then remarked that Englishmen had always been prominent in the work on the incandescent lamp, and that they had with them that evening Mr. Charles Batchelor, to whose brilliant work the perfection and successful introduction of the lamp in this country was so largely due. Another Englishman brought over by Mr. E. H. Johnson had been with Mr. Edison as his private secretary and confidant all through the period of storm and stress and was now lighting one of the dark places of the world with the Edison lamp, Mr. Samuel Insull, president of the Edison Medal Association.

Mr. Insull then presented to the Institute the Medal Fund and the Deed of Gift in connection therewith. He recited details from the Deed of Gift as to the nature and objects of the medal, which he characterized as the blue ribbon of the profession. He then proceeded in some brief, well-chosen remarks to outline the extent and importance of Mr. Edison's work; and while he did not minimize the lamp, showed it was but one detail in a vast and extensive system upon which depended the erection of an entirely new art.

Those prominent and distinguished experimenters who, prior to and contemporaneously with Mr. Edison, sought to produce a commercial incandescent lamp, followed the path hewn out for them by the early series arc light experimenters. They, as a result, made the mistake of producing a low-resistance lamp operating in series, and consequently requiring a varying potential, resulting in a system impossible to operate on a large scale. It remained for Mr. Edison, with a foresight almost supernatural, to see that what was needed was a constant potential system which would respond to the demand of every kind of service, and as a result he gave us the high-resistance lamp, the multiple-arc and feeder systems, embodying principles which all successful inventors have since been compelled to employ in their distribution systems—whether dealing with direct or alternating currents, with systems of lighting (except series-arc lighting), and with systems of electrical power, whether moving or stationary. In short, Mr. Edison gave us as the result of his brilliant inventive work at Menlo Park, the cardinal engineering principles of the great industry with which his name is so intimately associated, and in making these contributions to scientific and industrial progress he achieved such a position that I think posterity will not adjudge us of undue enthusiasm if we name him as the greatest electrochemical experimenter and the first electric light engineer of his day.

It is not alone as the experimenter and inventor, as the mathematician and engineer of this industry for which Mr. Edison is entitled to recognition. It should be borne in mind that at the time of his first exhibit of his light and power system on a considerable scale at Menlo Park in the winter of 1879-80, there were no factories for the production of the apparatus required for use in connection with the system, nor were there in existence, except in their crudest state, any of the numerous appliances used between the generator and the lamp, and which have since become every-day necessities. These appliances had to be developed and factories for their manufacture organized before it was possible to build the first plant and distribution system which was successfully started in New York in the fall of 1882. Things which to-day we do as a matter of course, because they have been done by others before us, presented great difficulties in the first ten years of the twenty-five years which this occasion marks. All these matters were dealt with under the guiding hand of Mr. Edison himself. The credit of carrying his great work as an inventor to a successful commercial issue is, therefore, due to him, and thus, besides being the inventor of his electric light and power system, he was in every sense the captain of the great industry resulting from his successful laboratory work.

I will not attempt on this occasion to mention the other branches of electrical work in which Mr. Edison has so greatly distinguished himself as an inventor and in connection with which he has contributed so much to the industrial development of our time. What he has done outside of the electric light and power field would be a sufficient life's work for most men.

The work that he has accomplished should prove a great inspiration to future generations of students of the electrical engineering profession. When, as a result of competing for the Edison Medal, which we hope will prove, so to speak, the blue ribbon of the profession [applause], they study the life of the great master after whom this prize is named, they will find that without any of the advantages of collegiate education, without any early training except that gained as a train boy and telegraph operator, blessed with little beyond a quick mind and a strong constitution, but with a will to work and a great power of concentration, this country boy from the West rose from so lowly a beginning to be the foremost electrical inventor of his time. [Applause.]

Dr. A. E. Kennelly, of Harvard University, past president of the Institute, then accepted the medal on behalf of the Institute and in thanking the members of the Edison Medal Association said:

I want, on behalf of the American Institute of Electrical Engineers, to voice our universal sentiment in expressing our appreciation of the cause which you have founded as a worthy and enduring monument to the fame of Mr. Edison. In the old days of Greece, in the days which were said to belong to the heroic time, men strove for the laurel crown. It was the idea of all men that the laureate wreath should rest upon their brow. To-day, in modern guise, and actuated by the more modern and altruistic spirit, this laurel wreath you have converted into a golden circle, that shall perennially flourish from year to year and pass from generation to generation to testify to the worth of the pioneer in whose honor it was founded. We want to thank you for what you have done in creating this fund. Not only do you incite enthusiasm in the young man, whose age is set forth in the deed as not to exceed twenty-five years; not only do you enhance the fame of Edison and perpetuate it in future years, but you also stimulate those institutions in which the future Edisons may be trained and engender this spirit of generous rivalry and emulation among the alma maters of this favored country. Broad and generous are the terms of the deed lying before us. Although our Institute is a corporation under the laws of the State of New York, this deed declares that any youth, of any country, educated at any college or institution from Texas to Labrador or to the Behring Straits, may qualify for this medal. Applied science and pure science know no barriers, and only understand and recognize the barriers of the unachieved and the unknown. The action taken here this evening should stimulate every worker in electrical interests all over this globe. I hope that this medal from year to year will inculcate some of the spirit in which this inventor strove and accomplished. It is a favorite saying of his that inspiration, in the main, is only another way of spelling "perspiration"; and that there is no secret so deep in nature, so recondite or remote, but persistent and ardent human labor will bring it to the surface. For that proposition this medal and this Institute stands. Moreover, you have set a golden seal upon this proposition—that pure science, or theory and applied science, or practice, are so closely connected, so intimately associated, in our modern life and in our modern dealings with nature, that the Edison medal cannot distinguish between them—that invention born of both throws lustre alike on both and forever will be a connecting link between them.

Prof. Cyrus F. Brackett, of Princeton University, was then introduced as one who had taught where Joseph Henry sat and who had had the distinction and honor of making the first scientific tests on the Edison lamp. He gave an interesting account of the manner in which these tests were conducted and spoke of the lively recollection he had of the difficulties encountered by Prof. Young and himself when, at the suggestion of Mr. Edison, they went to Menlo Park with such apparatus as the University then afforded to use in determining the efficiency of his dynamo employed in producing the incandescent lamp. Prof. Brackett said:

On behalf of the colleges and universities of the United States and Canada, I accept, with feelings of lively satisfaction, such responsibility as the founding and purpose of this medal confer.

It is fitting that such a medal be provided to bear witness to the skill and triumphs of the modest man whom we would honor on this occasion. I have said "would honor"; the fact is, that he has long been wearing, without affectation, the honors we are merely recognizing.

A mere enumeration of the things he has achieved would fill a very large and brilliant chapter in the history of applied science. His system of multiplex telegraphy, his invention of the telephonic transmitter, of the incandescent lamp, his system of electric distribution, his improvement of the dynamo, his invention of the phonograph—all these and many more which time does not allow me to mention, are the reasons for the honors which are his by well-earned right. And these, in some way, symbolized by the medals which shall be struck in his name, will prove a mighty stimulus to those who shall strive to obtain them as the years go by. As this occasion marks the twenty-fifth year of the art of incandescent electric lighting, it may be of interest to glance backward, for a moment, to the condition of the art of illumination, as it existed more than twenty-five years ago. Outside the large towns, into which gas had been introduced, the "tallow dip" and the whale-oil lamp maintained a doubtful contest with the powers of darkness, tried the patience of the saints, but did not abate the profanity of the wicked. Then came the era of the so-called "burning fluids" which, although better, could hardly be called means of grace. In the early sixties oil was "struck" in Pennsylvania. As a result the great whales and the "tar-heelers" had rest. The sunshine garnered through the ages, poured forth in every hamlet and hut. The candle was no longer placed upon the candle-stick, and everybody praised the bountiful Providence which had prepared such a luxury.

If any one ever saw an electric light in those old days, he was one of the favored few who had access to the dingy laboratory of the college professor, who, on stated ocasions, exhibited it as it left the hand of Davy. It was a most interesting spectacle, the memory of which is even now treasured by those of us who witnessed it.

But, although this arc light was too powerful for purposes of general indoor illumination, it demonstrated clearly to those who could forecast the future that electricity would have its place in the art of illumination whenever its cost should not be prohibitive, provided convenient distribution could be made.

Such was the condition of affairs when Mr. Edison undertook the solution of the general problem of dividing the current and distributing it to small incandescent lamps suitably placed. He solved it completely, and if we require a monument to this victory we have only to look around. Wherever this man may go in the wide world his pathway will be lighted by the results of his own genius.

Mr. Joseph B. McCall, of Philadelphia, president of the Association of Edison Illuminating Companies, was then introduced as one who, while just a little too old to compete for the medal, was not disabled from enjoying an equal distinction, namely, that of winning the golf cup of the Association, and as representing the gentlemen numerously in evidence that night who were doing all they could to give the world the best shine for five cents. Mr. McCall prefaced his remarks with some very humorous and pertinent anecdotes, outlined the history of the Edison Illuminating Association, and alluded to the splendid example that would be given the growth of electric lighting in the Edison Memorial Exhibit at the St. Louis Exposition. He said, in conclusion:

The year 1882 saw a total production of incandescent lamps of only about 100,000. Ten years later the total consumption in this country amounted to about 4,000,000 yer year, and in 1903, practically twenty-one years after, the manufacture of incandescent lamps was commenced in commercial quantities, the total consumption in the country reached about 45,000,000 lamps per annum. Think of it, gentlemen! It is not many years since, when, in the larger cities of this country, a connected load of 100,000 16-cp equivalent was considered a mark to work to, while now it runs up into the millions. I do not know that there is anywhere a record of commercial results than can compare with this. It is unnecessary for me to say what this has also meant in the great improvements which have been made in all kinds of apparatus and appliances. You know them.

A splendid lesson of this growth will be given at the St. Louis Exposition by the Edison Association—an Edisonian Exhibit, suggested by Mr. Insull, and now being prepared under his direction with great care and thoroughness, showing the great development from the small dynamos in the beginning to the great installations in the modern central stations. I am sincerely thankful for the privilege of being with your Institute to-night; grateful for the opportunity of paying my respects to the Great Man of Electricity, and I join your Society and guests in wishing for him many happy years, filled with continued good health, honors and successes.

The last speech of the evening was that made by Mr. C. L. Edgar, president of the National Electric Light Association. In calling upon him the toastmaster remarked that it was felt that the great perfection reached in the lighting art as a whole was due to the efforts of a great many distinguished and able men, among whom might be mentioned Elihu Thomson and Brush, Edward Weston and Swan, Wallace and Farmer, Fuller and Wood, Westinghouse and Hochhausen, Stanley and Steinmetz. The mention of the name of Thomson was received with long and continued applause, which did not cease until Prof. Thomson had risen to his feet and bowed. An ovation also followed immediately afterward in connection with the mention of the name of Mr. Coffin as a great captain of industry in the art and a great consolidator who brought it out of a period of chaos and confusion. Mr. Edgar said, in regard to the affair which had called them together that night:

I do not know who is responsible for the idea of the Edison Medal Association; whoever he is he deserves our thanks. I can conceive of nothing more appropriate than founding a fund, such as has been described here to-night, for the purpose not only of perpetuating Mr. Edison's memory and his work and his genius, but of perpetuating it among the class of young men to whom we must look for future development. I think it is particularly appropriate that the gold medal is to be given to the best work done by a member of the graduating class of one of our universities. I do not think that in the past there has been a very tangible connecting link between the students of our colleges and the men whose places they are to take in later life. I do not know how much the parent organization of the American Institute of Electrical Engineers is doing here in New York to bring them closer together. I do know, however, that the branch work which we are attempting to do in Boston and which I have no doubt is being done in other university centers is bound to have a very considerable effect in bringing closer together the students and the men engaged in the electric light industry in general. My recent connection with the Boston branch has shown me this more clearly than ever before. We have, as you all may know, in our vicinity, Harvard and the University of Technology, both having at least two large organizations of students taking an electrical course, and I venture to say that until the branch was organized scarcely any of them knew even by sight the class of men whom they themselves were likely to join in later life. What the branch work has begun in this respect will be made much more definite and tangible by the work inaugurated by the Edison Medal Association, and those in charge of its inception and carrying out are to be congratulated on having chosen a field, above all others, in which it will do the most good.

Before the assemblage broke up the New York Edison Company sent a photographer into the galleries and there an excellent picture was taken of the main table and 300 or 400 people still remaining. The explosion was very short, lasting only for a minute or two, and the picture is one of the best ever secured on a large scale by the means of the incandescent light. Thus closed fitly a memorable night.

The sextets written for the occasion by Mr. Bowker are appended:

LUX BENIGNA.

"Let there be light!" flashed the Creator's word,
And lo! the vibrant Vast with life was stirred,
Till last came Man. And Man is most divine
As he, with spark of genius, makes to shine,
Smiting the Dark to life, a living light
That into Day redeems the human Night.

FAMA ETERNA.

Blest is the man who, for his country dies;
Twice blest he who lives to serve mankind;
Thrice blessed he who, in life's little hour,
Searching God's treasure-house with lucent eyes,
A lamp for all men and all times may find,
And thrill the world with light, and heat, and power.

EDISON MEDAL DEED OF GIFT.

The Deed of Gift of the Edison Medal, as summarized by Mr. S. Insull, chairman of the Medal Association, provides as follows as to its chief features:

"1. The medal shall be awarded to such qualified student as shall have submitted to the Institute, in accordance with the provisions of this deed and of the regulations which may be prescribed by the Edison Medal Committee, the best thesis or record of research on theoretical or applied electricity or magnetism.

"2. Each competitor for the medal, in order to be qualified, must have graduated and received a degree during the year for which the medal shall be awarded, in some course of study at some institution of learning in the United States of America or Dominion of Canada, which course of study shall include the branch of electrical engineering. The United States Naval Academy and Military Academy are included within the institutions from which competitors may be qualified.

"3. Not more than two students may compete in any one year from any one institution of learning, nor may any student compete unless duly presented for competition through the faculty of the particular institution at which he is a student.

"4. The course of study must be one normally requiring not less than two years of continual residence and work.

"5. The thesis or record must not exceed six thousand words, not inclusive of words employed in explanation of accompanying drawings.

"6. No competitor shall be of greater age than twenty-five at the day of his graduation in such course of study."

Grounding of Constant Potential Systems.

BY S. BINGHAM HOOD.

THE object of grounding a constant potential system is to insure that under no possible conditions can the pressure rise above that normally on the circuit. This applies to all systems irrespective of the voltage at which they are designed to operate. The point at which the ground should be placed should be such that the pressure between the grounded leg and any other corresponding points shall be equal, or at the neutral point. Where it is impossible to obtain a neutral point then, of necessity, the attachment must be made to one of the other wires of the circuit, unless an artificial neutral is established.

To illustrate the object of grounding a system we will assume an arrangement of circuits commonly found in all large distributing systems (see Fig. 1). With all sections of such a system normally clear of grounds, the effect of accidental crosses and grounds will be taken up.

A ground on wire *a* gives a potential between ground and wire *b* of 5,500 volts; between ground and wire *c* of 7,700 volts. The same applying to accidental ground on wire *c*. With ground on wire *b* the potential to ground of wires *a* or *c* will be 5,500 volts. It is, therefore, clear that by permanently grounding wire *b* the possible potential is limited to the working potential of the circuit. Unfortunately, the general existing conditions prohibit such grounding on the high-tension section.

Most stations using high-tension feeders distribute either wholly or in part through underground cables. The first cables installed, some years ago, were insulated as in Fig. 2, each wire being insulated to withstand a pressure equal to that of the circuit, or double this

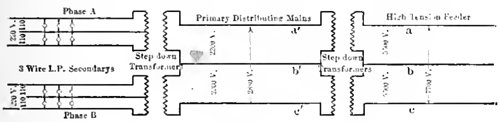


FIG. 1.—ARRANGEMENT OF CIRCUITS.

from wire to wire in the same cable. The several wires thus covered were built up into circular form and surrounded with a lead jacket.

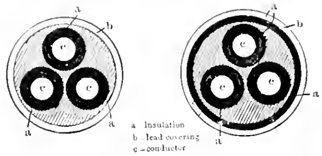
However, as the insulation between any wire and the lead sheath was only designed to withstand the working pressure, and when a ground occurs at any point on the system the factor of safety would be entirely wiped out, the result being a simultaneous breaking down of the insulation at other points on the system. In order to overcome this all new cables are, or should be, insulated, as in Fig. 3, the built-up cable having an insulation between it and the jacket equal to that on each wire. In this way a ground on any wire will not subject other points of the cable to potential above that for which it is designed to withstand. Unfortunately, the first type of cable is still largely in use, preventing permanent grounding until they are removed.

If a permanent ground were established it would not be necessary to place insulation on the grounded wire; consequently an additional amount of insulation could be placed on the other wires without increasing the cost.

Considering the middle stage of the system, the primary distributing mains, the same conditions apply as in the high-tension section; but owing to the lower voltage the danger of break-downs are not so great, but still exist to a very considerable extent.

Considering the effect of various grounds and crosses between the high-tension and primary systems, assume first a cross between wires *c* and *c'* with both systems clear of grounds, and no indication of trouble. A ground now occurring on wire *a*, the potential to ground of wire *c'* will be 7,700 volts, *b'* 9,900 volts, and *a'* 10,580 volts. This is the most severe condition which could exist, other combinations varying between this and a minimum of 5,500 volts, which can readily be determined by the data of Fig. 1. Should such a combination occur there would be an immediate break-down of the insulation at some point on the primary mains. With a primary system in first-class condition the weakest point would probably be between the coils of transformers feeding the consumers' premises, the breaking down of which would subject the inside wiring to a potential to ground of anywhere between 2,620 and 10,580 volts. The resulting disturbance requires no description. That such a result is seldom known to occur is explained in two ways: First, the general insulation of the primary system is seldom as high as that of the transformers connected to it, but the general improvement in overhead construction is rapidly removing this safeguard. Second, where such a break-down has actually occurred there is rarely enough left of the general combination, including the building where final ground connection was made, to tell what the original trouble was.

By permanently grounding wire *b'* any crosses between the primary and high-tension system would result in grounding the high-tension



FIGS. 2 AND 3.—SECTIONS OF CABLES.

wire upon which the cross occurred, either directly through ground connection on *b'* or through the transformer coils from wires *a'* or *c'*. It would, therefore, be impossible for any trouble, between these two systems, to spread to the low-tension secondary mains or to cause serious damage to the intermediate primary system. With both wires *b* and *b'* grounded it would be impossible for damage to result at any point except that where cross actually occurred. The same arguments apply to crosses between primary and the low-tension secondary mains, so that it is unnecessary to go into details as to the last section of the system.

The successful and safe operation of any constant-potential system requires that its voltage to ground must never exceed under any condition that normally on its circuits. From the above it should be clear that the only method of insuring such results is to permanently ground one wire of the system, and such grounding should be made compulsory in all cases where it is operated in conjunction with, or in the vicinity of, those of higher potential.

The illustrations and figures given above are taken from a three-wire, two-phase system, as offering the severest conditions to be found in practice. Single-phase, three-phase star, or delta, or combined star and delta give generally a slightly lower maximum voltage on the conditions shown above.

It is now necessary to consider the conditions to be met by grounding the low-potential distributing mains, an illustration of which, for future reference, is given in Fig. 4.

All low-potential circuits requiring over 660 watts should be wired and operated on the three-wire system, unless the load consists of one receptive device requiring over this amount of power, in which event it should be operated wherever possible from the outer wires of the system, thereby preserving the balance and requiring considerably less weight of conductors. The two-wire system, besides requiring an excessive investment for conductors, does not readily permit of grounding, owing to the grounded leg carrying the same amount of current as the other wire.

In a properly balanced three-wire system the neutral wire carries only a small percentage of the total current. By placing the per-

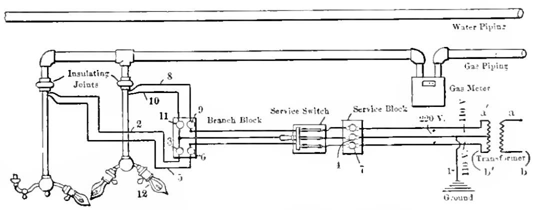


FIG. 4.—DIAGRAM OF GROUNDED CONNECTIONS.

manent ground on this neutral, should it accidentally open, the ground connections would not be called upon to carry any large amount of power; consequently, they need not be made as heavy or with as much care as would be necessary for their operation on a two-wire system.

A grounded direct-current, two-wire system might, under certain conditions, result in severe electrolytic action upon other metallic structures in its vicinity. This would not be true of a three-wire system, as the neutral current would be of small amount, and in most cases of an alternating character, reversing at each change of the unbalanced load.

Referring to Fig. 4, we will assume that ground connection 1 is made by a driven pipe or small plate buried in moist earth, the resistance of which under even the most favorable conditions will seldom be less than 50 ohms. With wire *b* (Fig. 4) grounded, a cross between wires *a* and *a'* will allow, with ground resistance above, a current of about 46 amp. to flow at a pressure of 2,310 volts. On a branch primary line or individual transformer this would probably be enough to open the protective device on the primary circuit. However, should wire *a* be a main feeder this current would not open the circuit-breaker, and, consequently, this current would continue to flow through the ground pipe and still leave all points on the secondary system at a potential of from 2,090 to 2,310 volts to ground. In addition, the wire, frequently uninsulated, leading from the line to this ground connection, would also be at this potential to ground, and a person touching it while standing on the street would probably receive a fatal shock. The writer recalls one instance where the drop of potential was between such a ground and a street railway track about 15 ft. distant, and a horse crossing the line between pole and track received sufficient current to cause him to shy and turn around in line with the current path. The drop of potential through the earth between his hind and fore feet was then sufficient to instantly kill him, although at no time was he in actual contact with the charged pole or the railway track. This is one of the most forcible illustrations of the dangers of imperfect grounding.

While this current was flowing it will be supposed that the insulation to ground at point 2 was destroyed, and a low-resistance connection established to piping or other conductor connected to ground. This would produce a short-circuit at 2,310 volts through the house wiring and neutral service, resulting in blowing of fuses 3 and 4. The high potential would then establish a destructive arc at these points, probably starting a fire before the large breaker on *a-b* could open. This is identically what would happen under the same conditions if the ground pipe or plate had been omitted. It is, therefore, clear that a ground of this character, while furnishing protection in some cases, is worse than useless, as it furnishes a fancied protection, which in reality does not exist.

Considering the secondary feeders as being clear of other systems, a ground is placed at 5 on wire *b'*. There will now be a circuit established through the accidental and permanent ground, with a resistance of 50 ohms, neglecting resistance of wires. This allows a current of slightly over 2 amp. to flow, or insufficient to blow the fuses at either 6 or 7, and there being no indication of this trouble it would be allowed to exist. This places all points on wire *a'* at a potential of 220 volts to ground, with neutral at 110 volts to ground, being the same as if the ground connection at 1 did not exist. A ground occurring at 8 on wire *a'* would produce a 220-volt short-circuit between 5 and 8, probably blowing fuses 6 and 9. These fuses could not be replaced until one of the grounds is removed. Assuming that the one at 5 is cleared, then ground 8 allows the same conditions to exist on the opposite side of the circuit or system.

Instead of this combination we assume that ground occurred at 10, with ground 5 still on. There is then a 110-volt short-circuit between neutral and *b'*. The wireman sent to repair this does not readily locate grounds 10 or 5, gets disgusted, reverses circuit by placing wire 5 in fuse 3, and wire 2 in fuse 6, puts in the fuses and reports everything O. K. There are now two "permanent and effective" grounds on the neutral, in addition to the ineffective one at 1. All is well and good until a cross occurs between the secondary system and some high-potential circuit, when the result is a job for the insurance adjuster.

Another frequent and generally serious result is caused by fuse 11 blowing before fuses 6 or 7, resulting in 220 volts being thrown into all receptive devices on circuit 12, and in their immediate and violent destruction.

If the ground connection, 1, were made to an underground piping system the resistance would not be over one or two ohms, in which case a cross between a high-potential circuit would immediately open its protective device and also prevent such a high potential from reaching the main part of the consumer wiring before such device had opened. It would also be impossible to hold a fuse until the grounds occurring on the outer wires had been removed. It would still be possible to clear these grounds by reversing the two-wire branch, throwing the ground on the neutral; but this would not be likely to have any serious results owing to the low resistance of the permanent ground. A method of preventing this reversal will be taken up later.

It is, therefore, evident that a neutral permanent ground must be required, but that such ground must be of extremely low resistance. The only method of obtaining such a ground is by attaching to an underground piping system. This cannot readily be accomplished below the ground level, owing to the necessity of opening the street to reach such a pipe, and to the difficulty of obtaining a satisfactory and permanent connection when the pipe is buried in the earth and subject to all street disturbances.

The only practical method is to attach to a gas, steam or water pipe on the consumer's premises. This should be made before reaching the consumer's service block or switch, and to the service side of any gas meter.

Every consumer should be so connected in order to insure that the removal of one connection may not leave the entire system unprotected. In the case of consumers fed from individual transformers at least two grounds should be made in order to insure that failure of one will not permit the system to operate ungrounded. In the case of a large secondary network there would be a multiplicity of grounds capable of carrying many times the total current on the system.

In buildings of timber construction it would be well to require that the gas meter outlets be bridged by a substantial bond, and also that gas piping be connected to other piping systems. The reason for this is that if gas piping should not be in electrical connection with other piping systems in the building, and a connection be established with the electrical wiring, current would flow through the gas meter.

Should the gas meter outlets be open, owing to absence of the meter, there would be a potential of 110 volts across the outlets. This would hardly apply to water meters, unless the meter was absent, as it is almost an impossibility to overheat a pipe or meter containing flowing water with any current generally used in one building.

To safely operate a three-wire system the neutral must remain closed under all possible conditions of service, in order that the receptive devices cannot possibly receive the full voltage between outer wires. Contrary to this, the present rules require both fuses and switches on this neutral wire, the accidental opening of which constitutes a serious fire risk. All protective devices should be required to be placed on the outer wires only, the neutral being run continuously to all points. In addition, the neutral should be permanently grounded at every distributing point, and at each outlet (provided a grounded pipe is available at the outlet), the object being that should the neutral conductor become broken the piping systems would preserve the continuity of the circuit. When it is considered that a ⅜-in. pipe, the smallest used in piping buildings, will safely carry 50 amp., and that the unbalanced load on a system never exceeds 25 per cent. with the most careless balancing, such a pipe would supply the maximum neutral current for 800 lights. Taking into consideration that but a small part of the piping in a building is so small, the danger of overheating it is insignificant compared to the risk from a broken neutral. The pipe joints being all made by screw threads their conductivity could be assumed as being at least equal to that of the pipe itself, so there would be slight danger from this source.

This method should, however, not be construed to permit the use of the piping system as a permanent conductor for the neutral current, the object only being to insure the continuity of the neutral should the normal path become defective. The piping being in multiple with the neutral conductor will, of course, carry a proportion of the current; but, as such piping is capable of safely carrying the total current, there would be no danger of overheating. Further, should a bad joint occur in the piping the resistance would be raised and the current automatically decreased in the pipe and increased in the neutral conductor. Should a bad joint occur in the same section as a broken neutral, there would, of course, be a heating of the joint. In practice this would not be likely to occur. A joint sufficiently bad to offer any appreciable resistance would not be sufficiently tight to hold gas. The chances of such a combination occurring are probably not one in a million, and further, should it occur there would be a disturbance in pressure at the receptive devices with an unbalanced load, sufficiently great to be investigated at once.

An attempt to attach an electric circuit to piping systems is generally met with opposition from the general public, owing to the impression that a shock may be received from such piping. That such is an impossibility is clearly evident when it is considered that such piping must of necessity be at earth potential, or the same as that of any person standing upon the ground or other earthed conductor.

Having shown the necessity of thoroughly grounding the neutral, it is evident that to require any insulation upon it is clearly a waste of both labor and material. This neutral could be run with bare copper conductors, rigidly secured to the building (but not insulated from it) or pulled in with other wires in conduit systems, all joints and taps being made up solid in preference to any screw-connecting devices. It should be carried direct to all outlets and not to any switch or controlling device. Such switches should be placed on outer wires only, being double-pole on three-wire mains and single-pole on two-wire branches. There are two reasons for this: First, double-pole snap switches frequently become short-circuited from careless handling. Second, any fixture ground can be rendered harmless by opening the outside wire at the switch, which would not be possible were the switch placed on the neutral. This applies to all grounded systems irrespective of whether bare or insulated neutral is used.

Let us next take up the wiring of fixtures, particularly those known as "combination," in which gas and electric arc used on the same fixture. Owing to their generally poor construction these fixtures are not adapted to electric wiring in a permanent form. The practice is to file a notch in the shell of parts slipped over the main supporting stem, the conductors being carried successively through these notches. A slight turning of any of these shells results in grounding the fixture to the wiring.

Should the wire so grounded be an outer there would then be a short-circuit through the permanent ground on the neutral. The practice of placing an insulating joint between the fixture and supporting pipe renders the completion of such a short-circuit impossible, leaving a potential of 110 volts across the members of this joint; and there being no indication that this trouble exists it is allowed to continue. Were there no gas in the piping, the chances of any further trouble would be remote; the gas, however, deposits a film of carbonaceous composition across the insulation on the interior of the joint, permitting a slight leakage of current across the gap. This deposit becoming greater in time, and being further carbonized results in heating of the joint, destroying its gas-retaining qualities. If the heating becomes sufficiently great the gas will become ignited at this point, and the flame, being sucked up between ceiling and floor, spreads beyond control in a surprisingly short time. While this carbonization may require years to reach a dangerous value, the final disruption is very rapid, resulting in a fire without any appreciable warning. The use of these joints constitutes one of the greatest fire risks from electric wiring and should be condemned at once, irrespective of whether the system is grounded or operated clear.

In place of these joints a solid brass coupling should be used, having cast upon it a substantial screw connection for attachment to the neutral conductor of the circuit. The fixture lead connected to neutral or grounded feed could, and preferably should, be of bare copper wire, extending from top of fixture to the sockets. This would leave room in fixture for a heavier insulation on the outside wire, and would also prevent the reversal of any portion of the system in order to throw an accidental ground on the permanently grounded leg of the circuit.

An installation using such a full grounded system would be absolutely free from any danger from crosses with high-potential circuits or from lightning discharges, and could not be operated with any but the intentional ground on the system. With the permission of the Underwriters, such a system would be immediately adapted by all contractors, owing to its being installed for from 10 to 20 per cent. less than under the present rules. One such installation would furnish protection to all the old installations on a network, thus reducing the fire hazard on all the older work.

This full-grounded system being permitted, manufacturers could profitably bring out a line of wire and fittings along the following lines:

Wire.—Conduit wire, fixture wire and flexible cords to be heavy rubber-covered, braided wire, surrounded by an armor of copper ribbon or woven copper gauze, such armor to be used as the grounded conductor of the circuit.

Distributing Cabinets and Switchboards.—For three-wire to have but two buses, with double-pole fuses and switches; two-wire branches to have but one fuse and switch. This would allow practically double the spacing now possible, without increasing the size of the board.

Fixture Sockets.—Outside shell and outer contact to be in electrical connection. Inner contact to make and break, for key sockets, on outer wire binding post, the post being arranged concentrical with outlet pipe, allowing the socket to be screwed on fixture without bending or kinking wire in any way; no connecting post to be placed on outer contact, the fixture arm to be used as the grounded conductor. Bare stem wire, or armor on armored wire, to be connected to fixture body at bottom of fixture; such body preferably being made of brass and having a connecting lug cast upon it, similar to that upon the connecting joint at top of fixture.

The electrical fire risk in any building equipped with an electric installation using wire and fixtures as above would be practically eliminated, any trouble occurring being confined to the interior of the grounded armor for sufficient time to allow of the opening of the protective device, and such device could not be kept closed until the trouble was removed. It being a physical impossibility to remove the permanent grounds on the system, this trouble could not by any possibility be shifted in such a way as to place another fire risk upon the circuit.

The entire working conductor being surrounded by a grounded shield, it would also be impossible to receive any shock from the wires or fixtures, unless this shield was intentionally removed. This would remove one of the great objections of the general public to grounding under the present system of wiring.

Tesla Patent Decision.

Judge Seaman of the United States Circuit Court of the Eastern District of Wisconsin, has handed down a decision on a motion for a preliminary injunction against the National Electric Company, applied for on the grounds that a polyphase synchronous motor manufactured by that company infringed four Tesla patents granted May 1, 1888, two of these being fundamental patents and two on specific means. The injunction was denied on the grounds that previous decisions sustaining Tesla patents did not pass upon the question whether they also covered polyphase synchronous motors.

Judge Seaman discussed the several opinions sustaining Tesla patents, beginning with that of the New England Granite Company case, and concluded that the terms of these only apply to polyphase non-synchronous motors. The sweeping opinion in the New England Granite Company case he considers must be treated as modified by subsequent opinions, and he quotes Judge Brown to the effect that Tesla discovery was not broadly the use of alternating currents of different phase with an ultimate object of rotating any shaft. No case involving the use of a motor operated in synchronism has been brought to final hearing, though such use constantly appeared, while litigation was vigorously prosecuted against non-synchronous infringements—one instance being that of the continuous manufacture of synchronous motors by a defendant, who was under injunction against infringement by a non-synchronous motor in suit and this without interference until lately. The question of infringement in the present case under the fundamental facts depends upon the scope of the invention and involves a broader construction than was involved in any other prior cases, and consequently the court denied the motion for preliminary injunction.

Wireless Telegraphy in Alaska.

A dispatch from Tacoma, Wash., states that wireless telegraphy between Nome and St. Michael has practically failed, the distance between the two points being too great for successful transmission during winter weather. It is suggested that the government establish two more stations in order to accomplish the desired result. Stations have already been established at Port Safety, near Nome, and St. Michael, at a cost to the government of $6,000. The distance across Norton Sound between the two existing stations is about 125 miles.

Efficiency Test of 1250-K.W. Steam Turbine for Interborough Company, New York City.

By A. M. Mattice.

DURING the present period of rapid introduction of the steam turbine, it is of especial interest to observe its economic performance under conditions of test approximating those of future daily service. Data of definite and dependable character has, in many cases, been of such noticeable scarcity that results of carefully-conducted tests should merit special attention and credence. The following presents the most important results of a series of performance tests conducted at the builder's works upon a 1,250-kw Westinghouse-Parsons steam turbine-generating unit, the first of the three units selected by the Interborough Rapid Transit Company for the illumination of the New York Subway. The tests were executed on October 12-15, 1903. The calibration of the various instruments and the computation involved were all verified by Julian Kennedy, consulting engineer, Pittsburg.

CONSTRUCTION.

Turbine.—The turbine is of the two-cylinder, multiple-expansion, parallel-flow type, arranged in tandem compound and direct-connected through a flexible mechanical coupling to the generator. The three sections of the unit are mounted upon a single bedplate, thus making the unit self-contained. Both turbine cylinders are covered with non-conducting material secured in place by sheet-steel lagging. In the pipe connection between the outlet of the high-pressure cylinder and the inlet of the low-pressure is inserted a separator. The condensation collecting at this point is normally removed by a trap, but during the tests the water was collected in a vessel of known cubical contests fitted with a water gauge. After recording the amount separated the water was returned to the exhaust main and was subsequently included in the total steam consumption.

The turbine is governed by a fly-ball governor of great sensitiveness, positively driven from the end of the shaft. Steam is admitted in short puffs at intervals of about 2½ seconds, the duration of each puff being controlled by the governor mechanism. The admission steam is thus not throttled in proportion to the load, but is always admitted at approximately boiler pressure, thus securing the highest efficiency from the temperature range available. The governor spring tension is adjustable by hand during operation, so that the speed of the turbine and consequently the load (if operating in parallel with another unit) may be readily controlled. In addition to the regular governor, the turbine has an overspeed safety governor which operates with high-pressure steam an automatic quick-closing throttle valve inserted in the main steam pipe. This governor is positively driven from the turbine shaft and may be adjusted to operate at any predetermined overspeed.

Overload capacity up to 50 per cent. of normal rating is secured by a hand-operated by-pass valve admitting high-pressure steam to the second stage of the turbine. The effect of the by-pass is well shown in the economy curves.

The bearings of the turbine unit are continuously and automatically lubricated by an oil-circulating system operated by a small plunger pump driven from the turbine shaft. This pump delivers oil under a head of about 18 inches. This gravity head is sufficient to thoroughly flush the bearings, which are of the flexible shell construction and of sufficient size to avoid the use of any oil under heavy pressure. The oil is returned to a reservoir in the bedplate and is cooled on its way to the bearings in a copper coil surrounded by cold water.

Generator.—The turbo-generator is of the revolving field type delivering three-phase, 60-cycle current directly to the distributing system at a pressure of 11,000 volts. The unit operates at a speed of 1,200 r.p.m., thus requiring a six-pole field. The rated capacity at full load is 1,250 kw with 25 per cent. continuous and 50 per cent. intermittent overload capacity. As efficiency tests had been periodically made upon the generator, no detailed tests were made at this time, but the entire unit was tested as a whole, from steam input to electric output.

Fig. 1.—General View of 1,250-kw Turbo-Generator.

Contract Guarantees.—The contract provisions covering the efficiency of the unit were as follows: With 175 pounds steam pressure at the throttle, 27 inches vacuum, measured by mercury column and referred to a 30-inch barometer, the consumption of steam at various loads should not exceed the following:

	Dry Saturated Steam.	Steam Superheated 75° Fahr.	
Full rated load	15.7	13.8	lbs. per e.h.p. hour.
¾ "	16.6	14.6	" " " "
½ "	18.2	16.2	" " " "
¼ "	23.2	20.8	" " " "

Method of Test.—After being assembled complete in the erecting shop, the turbo unit was transferred by traveling cranes to one of the testing foundations. As no foundation bolts are used no further preparation was necessary to operate the turbine than to connect up to the steam and the 36-inch exhaust pipes, each of which has outlets at the various testing pits.

During the superheated-steam tests, the steam was superheated by an independent gas-fired superheater, which forms part of the permanent testing outfit in the Westinghouse turbine shop.

The exhaust steam was condensed in an Alberger counter-current surface condenser, provided with separate dry and wet air pumps, the former being of the two-stage type with Corliss gear. This condenser is one of several employed only for testing purposes. It was tested for leakage immediately before and after the tests, and the correction applied to the observed steam consumption of the turbine.

At the conclusion of each test the water in the drainage or hot well of the condenser was left at the same height as at the beginning. Even a considerable error in this respect could have no material effect on the results. The hot well is 36 inches in diameter, and, assuming the temperature of the water to be 110° F., a depth of one inch of water would be equivalent to 36.5 pounds in weight. In the case of a turbine developing 1,000 ehp, for instance, at a consumption of 14 pounds of steam per ehp hour, the total steam used in one hour would be 14,000 pounds. If, then, an error of one inch should be made in the level of the water in the well after a one-hour test, the error would amount to only 35.5/14000, or about one-quarter of one per cent.

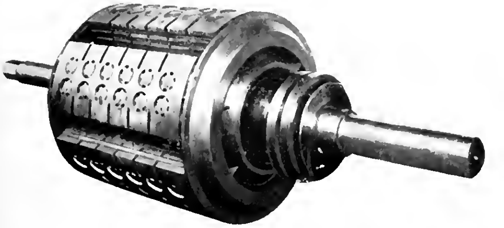

FIG. 2.—ROTATING FIELD.

The tests were conducted in the same manner as are the regular commercial tests of all turbines built in the Westinghouse shops. The number of tests was, however, greater than is usually called for, and extreme accuracy was secured by the duplication of all instruments. Throughout the several tests all readings, including weighings of condensed steam, were made at intervals of five minutes.

Measurement of Load.—The electrical load was applied by means of a large adjustable water rheostat, which also forms part of the regular testing outfit. As the generator pressure of 11,000 volts might prove a source of danger to the attendants if passed directly into a water rheostat, the voltage was reduced by step-down transformers to about 550 volts. All electrical measurements were, however, made between the generator and the transformers.

Voltage was measured by two voltmeters, one being used as a check on the other, the pressure on the instruments being reduced by potential transformers having a ratio of 100 to 1. Each of these voltmeters was arranged so that it could be plugged in between any of the three terminals of the generator.

Current was measured by a duplicate set of long-scale, dead-beat ammeters. In each of the three phases were inserted two-current transformers, in series, each connected to a low-voltage ammeter. In addition to the two ammeters in each phase, a carefully calibrated Siemens dynamometer was plugged into the various phases at each reading. The dynamometer readings alone were used in the case of the lightest loads, by reason of the difficulty in reading the ammeters with sufficient accuracy for the purposes of the test. At each reading three successive observations were taken.

All the electrical instruments, including the potential and current transformers, were carefully calibrated in the Westinghouse Electric & Manufacturing Company's standardizing laboratory immediately before and immediately after the tests.

Pressures, Temperatures and Speed.—Steam pressure at the throttle was observed by a duplicate set of gauges and vacuum by a mercury column connected to the turbine exhaust.

Temperatures of steam were measured by duplicate thermometers inserted in thermometer cups in the steam pipe. During the saturated-steam tests two throttling calorimeters were used and the quality was maintained as near as possible to that of dry saturated steam by drying it in the superheat just enough to evaporate the moisture which had condensed in the long run of piping leading from the boilers.

The speed of the turbine was ascertained from the speed of the oil pump, which is geared to the turbine in the ratio of 31 to 4. A tachometer was used to detect sudden small variations of speed, if such should occur, as well as to show the speed regulation when the load was suddenly increased and decreased. The records of speed, however, did not enter as factors in the measurement of power, which was ascertained entirely by observations of the electrical output.

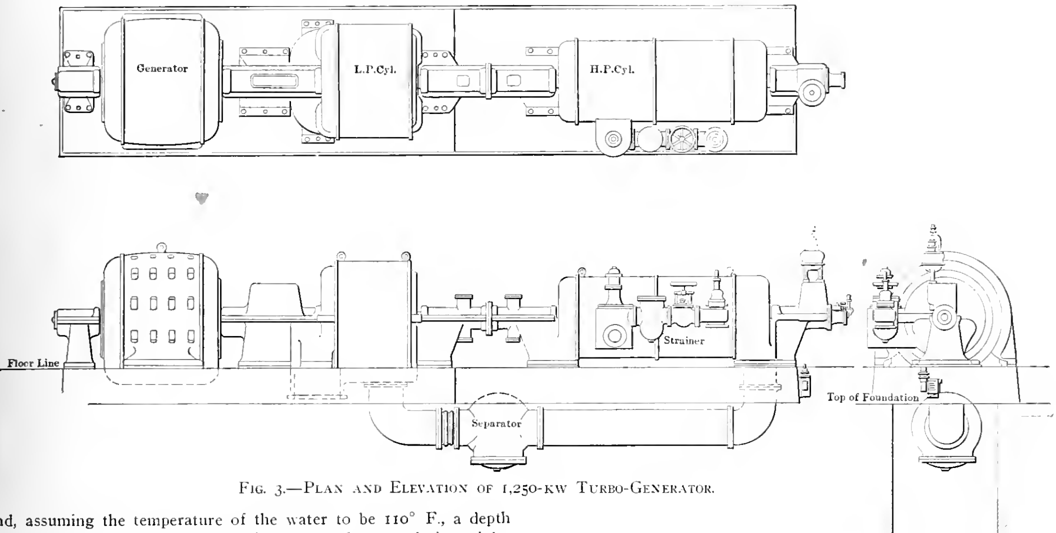

FIG. 3.—PLAN AND ELEVATION OF 1,250-KW TURBO-GENERATOR.

FIG. 4.—ROTATING FIELD.

Regulation Test of Speed.—At the conclusion of the economy tests, a load of 1,309 kw was thrown off by opening the exciter circuit, with a resulting increase of 2 per cent. in speed. A load of 1,342 kw

was then thrown on and a speed variation of 2.2 per cent. in the opposite direction was shown. This load on being thrown off showed a speed variation of 2.07 per cent.

Test of Safety Stop.—The speed of the turbine was increased by holding down the main governor lever, thus preventing the governor

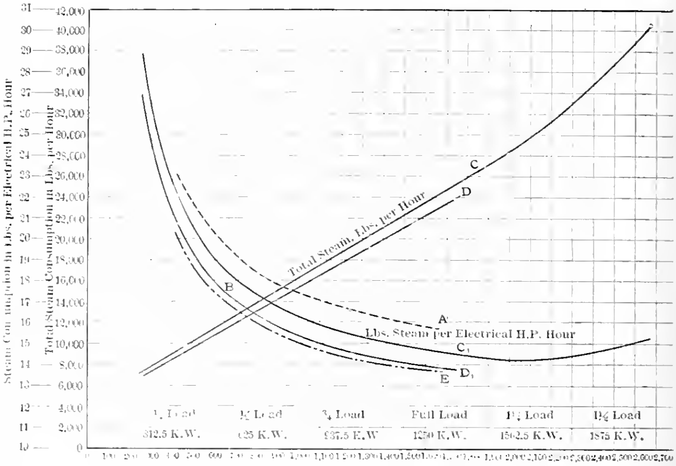

FIG. 5.—CURVES SHOWING GUARANTEED AND ACTUAL STEAM CONSUMPTION.

from controlling the speed. At 1,372 r.p.m., or 14.35 per cent. above normal speed, the safety stop operated and brought the turbine to rest.

Results of Economy Test.—The results of the tests for steam consumption are shown by the accompanying table. The tests from light loads to full rated load with 27 inches vacuum were made to determine the fulfilment of the contract guarantees, but the overload tests and those on 28 inches vacuum were made for general information. The tests were limited in scope and number by the necessity of removing the turbine from the testing floor to make room for other commercial work.

The tabulated results are shown graphically by the accompanying curves, Figs. 5 and 6. Fig. 1 is a comparison of the guaranteed

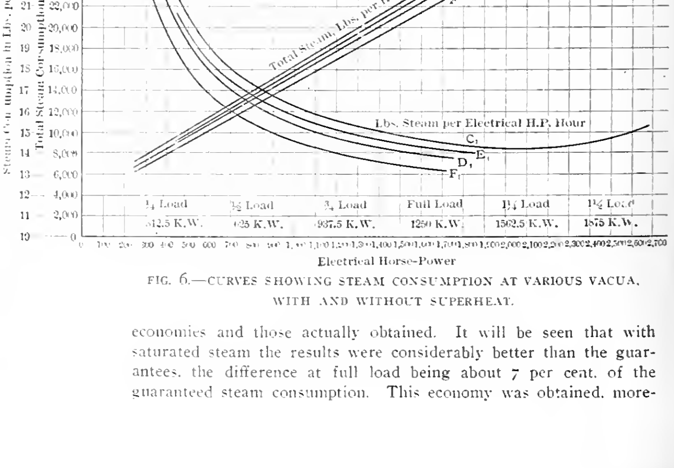

FIG. 6.—CURVES SHOWING STEAM CONSUMPTION AT VARIOUS VACUA, WITH AND WITHOUT SUPERHEAT.

economies and those actually obtained. It will be seen that with saturated steam the results were considerably better than the guarantees, the difference at full load being about 7 per cent. of the guaranteed steam consumption. This economy was obtained, moreover, with steam of only 147 pounds pressure, instead of under the contract condition of 175 pounds pressure, as the higher pressure was not available.

With superheated steam at the same pressure, the tests showed an economy so close to the guaranteed results that the difference is hardly perceptible in the curves. An additional curve (*E*) has been plotted to show the probable steam consumption which would have been obtained if the contract steam pressure of 175 pounds has been available, this curve having been computed on the basis of tests on other turbines at various pressures.

Fig. 7 shows these results, with the omission of the guarantee curves and the addition of the curves of steam consumption under

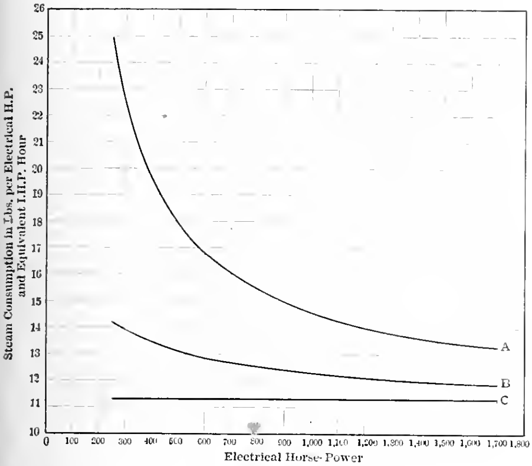

FIG. 7.—CURVES OF ECONOMY WITH AND WITHOUT SUPERHEAT, AT DIFFERENT VACUA.

28-inch vacuum, thus giving a comparison of the economy with and without superheat, and with different vacuna.

An important result shown by curve *C*, Fig. 2, is the effect of the by-pass on overloads. The material difference between the curvature of *C* and the by-pass curves published heretofore lies in the method of manipulation. If, when the turbine reaches full load, the by-pass is opened full, the water rate is suddenly increased by a small amount. As the load is further increased, the economy gradually improves and at the limit of the turbine capacity the full load water rate has nearly been reached. In the tests represented by curve *C* the operation was reversed, the by-pass valve being opened by hand at the various loads only sufficient to maintain normal running speed. Thus the by-pass steam is approximately proportional to the overload upon the turbine. The rise in the curve is marked only on heavy overloads, when the valve is nearly open and the best economy of the turbine is thus maintained throughout moderate overloads.

The curve *C* thus presents a striking similarity to the economy curve of a piston engine, except that the rise on under and overloads is less marked; or, in other words, the economy is greater.

Furthermore, a piston engine with the usual cut-off gear reaches its best economy at about three-fourths full load rating, the steam consumption being considerably greater at full load and increasing rapidly on overloads. The turbine, however, preserves its best economy, occurring at about full load, through a considerable range of overload, with the result that operation during peak loads on the station may be accomplished without the loss of efficiency occurring in engine operation.

COMPARISON WITH RECIPROCATING ENGINE.

From the curves it might at first appear that the steam consumption of the turbine is high at light loads, as compared with that of a reciprocating engine of corresponding size. Such an idea might naturally arise from the fact that it is customary to think of engine economy as steam consumption per indicated horse-power rather than per brake or electrical horse-power. The indicator does not, however, reveal engine or generator losses. In the turbine tests here described both are included in the figures on steam consumption.

In order to bring this point out more clearly, take for instance the results obtained under 75° superheat and 28 inches vacuum, shown in curve *A*, Fig. 7. The steam consumption at full load is 13.25 pounds, and at one-quarter load 19.25 pounds per ehp. If, for comparison, a combined efficiency of 90 per cent. be assumed for the piston engine and direct-connected generator, the steam consumption of the turbine per equivalent ihp would be 11.9 pounds at full load, which rivals the best modern steam engine performance.

The most marked economy of the turbine, however, in comparison with the engine, occurs at light loads. Assume now a reciprocating engine unit in which the total losses are constant at all loads, and also that the steam consumption per ihp is constant at all loads. Will the turbine meet these assumptions? And, under these conditions of constant losses and water rate, what will be the relation of water rate to output? Manifestly the total losses of the hypothetical engine, which amounted to 10 per cent. of the indicated work at full load, will be 20 per cent. at half load and 40 per cent. at quarter load. The corresponding efficiency will, then, be 90 per cent. at full load, 80 per cent. at half load and 60 per cent. at quarter load. It is safe to say that the extent of this lost power at light loads in the engine is not generally appreciated.

Considering further the assumptions, it should be borne in mind that they are greatly in favor of the reciprocating engine and do not represent actual performance. Firstly, the usual combined efficiency of a high-grade engine unit is more nearly 85 per cent. than 90 per cent., and even 85 per cent. is attained by few makes. Secondly, the indicated water rate of the engine is far from constant, whereas experience and data show that the water rate increases on both under and overloads. A test made by Prof. Jacobus upon a compound four-valve engine fitted with reheating receiver and steam jackets illustrates this point. The engine showed maximnm economy at about 700 ihp; at half the load the water rate increased 24 per cent. and at 1,000 maximum ihp nearly 7 per cent.

The assumption of constant losses is not far from correct for well-designed machines. Brake tests show that friction losses at heavy loads are but slightly greater due to the greater pressures on the various parts. Generator losses are likewise nearly constant. In the generator under test, the increase in loss from full to 1/4 load was less than 1/2 per cent. of the rated capacity.

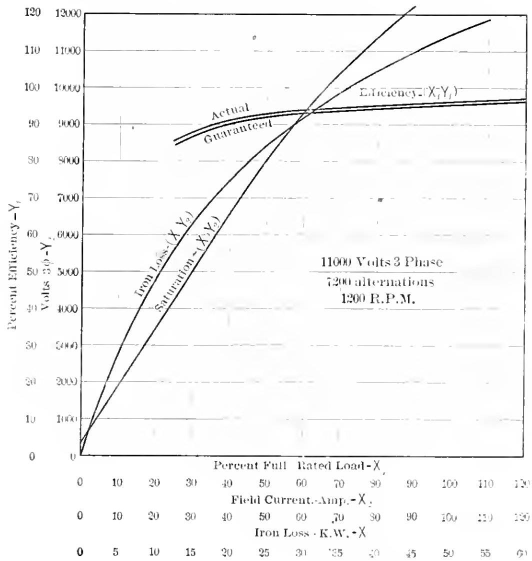

FIG. 8.—CURVES OF SHOP TEST OF 1,250-KW TURBO-GENERATOR.

Compare now engine performance with that of the turbine here described. Curve *A*, Fig. 7, shows the actual steam consumption per ehp hour. Curve *B* shows the consumption per equivalent ihp, under the assumption of constant losses and water rate, and of 90 per cent. combined efficiency at full loads. The increase in steam consumption at half load is but 4.6 per cent. and at overload the consumption decreases rather than increases.

Following out this method with an assumed total efficiency of 85 per cent., instead of 90 per cent., results are obtained shown in curve *C*. The indicated water rate of the turbine is 11.26 pounds and it is constant at all loads, thus confirming the original assumptions. In order to meet these results a piston engine must not exceed a water rate of 11.26 pounds per ihp at full load and must maintain this economy throughout its range of load.

The superior efficiency of the turbine finds explanation in the fact that expansion is approximately adiabatic; that the cylinder remains constantly at the temperature of the working steam and is not alternately heated and cooled as in the piston engine. Although mechanical losses in the engine are so nearly constant, the thermodynamic losses are so pronounced, particularly at fractional loads, as to preclude comparison with the steam turbine.

GENERATOR TESTS.

Individual tests on the turbo-generator were made in the Westinghouse Electric & Manufacturing Company's shops previous to the combined tests above described. These shop tests included the measurement of iron loss, determination of the saturation curve and short-circuit tests, and preliminary temperature runs. The characteristics of the generator are as follows: 1,250 kw, three-phase, 11,000 volts, 60 cycles, the full-load current being 65.6 amp. per terminal. Separate excitation of the generators is employed.

Results from some of the tests are shown graphically in Fig. 8. The actual efficiencies obtained were as follows:

	Actual.	Guaranteed.
1¼ full load	96.5%	96%
Full load	96	95.5
¾ "	95	94.25
½ "	92.7	92
¼ "	86	85

Following the customary practice, these efficiencies are calculated from measured electrical and magnetic losses, bearing friction and windage not being included. The short-circuit current of the generator is approximately 3¼ times the full-load current. The generator was run on open circuit for 11¾ hours at 12,150 volts, with full excitation. Under these conditions the maximum observed rise in temperature in stationary iron was 26.7° C. by thermometer, and the corresponding rise in the temperature of the field 16.7° C. With full load thrown off, the rise in voltage as estimated from the short-circuit test and armature resistance is under 6 per cent.

The Patent Office in Germany

The *Frankfurter Zeitung* of December 6, 1903, says: "The German Patent Office is overwhelmed with work. The number of applications for patents is still increasing. It was 27,565 in 1902 and will be about 29,000 in 1903 and 30,000 in 1904. Trade-mark applications for the last few years show an increase also. They were 9,924 in 1901, 11,168 in 1902, and will be about 12,000 in 1903. A further increase for 1904 is expected. Of the present five directors of the Patent Office four are lawyers and one a technologist.

"Another director is to be added. His duties will be principally to assist the president of the board of directors with reference to the technical personnel of the office, as well as to the general technical matters of the office, which, on account of the close relations of the patent office to the industries, are constantly becoming more important.

"Seventy-two technical clerks are at present employed in the examination of patent applications. In consequence of the great work involved in the examination of the steadily-increasing material, this force has become inadequate. An increase of nine technical clerks is necessary.

"In the two divisions for trade-marks there are at present, in addition to the two chairmen, five law and five technical experts and five assistant law referees. The necessity has arisen to increase the lawful organization of the division through additional members and cut off some of the assistants who can only take the place of a member to a limited degree. For 1904 two new lawyer members are required."

The Lamme Single-Phase Railway Motor.

We are enabled to present herewith illustrations and a description in detail of the Westinghouse straight-series, single-phase railway motor, which formed the subject of the English patent noticed in these columns last week.

The motor shown has a nominal rating of 125 hp on the basis of a one-hour run at full load with rise of temperature not exceeding

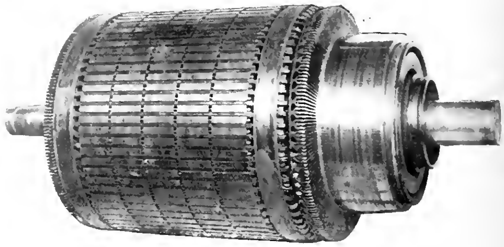

FIG. 1.—ARMATURE WITH COMMUTATOR AND BEARINGS.

75° C. Mechanically, it follows the general lines now regarded as standard for direct-current railway motors. The principal features peculiar to the new type are found in the construction of the magnetic field and in the winding of the armature and field coils. It is

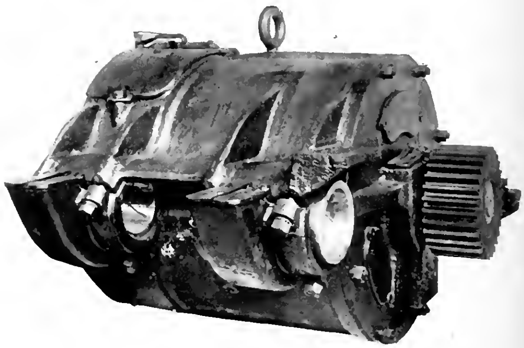

FIG. 2.—MOTOR, FRONT VIEW.

scarcely necessary to say that the motor is series-wound and of the commutator type.

The field frame consists of a cylindrical shell of cast steel, to which are bolted solid end brackets of the same material. These end

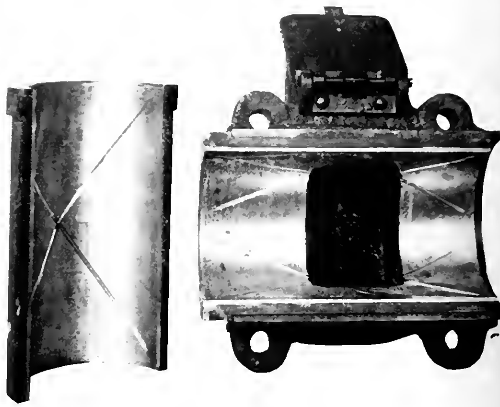

FIG. 3.—AXLE BEARINGS, BABBIT-LINED.

brackets contain supports for the armature bearings. The upper caps of the axle bearings are cast solid with the frame. The lower caps are rigidly held in place by heavy bolts. The axle bearings consist of cast-iron shells lined with babbit and divided into two parts. Solid shells, also babbit-lined, are used for the armature bearings. The bearing boxes are large and are packed with waste and oil lubrication is used throughout. The extensions which carry the axle bearings are especially strong and heavy. There is a large opening in the upper frame which permits access to commutator and brushes, and numerous hand holes are provided both in the end brackets and bottom of the motor. Lugs for "nose" suspension and support of the gear case are cast solid with the frame.

The field core is made up of circular punchings of soft laminated steel. The poles are rectangular in section and project inward, thus forming a magnetic circuit which is wholly laminated and without break from pole face to pole face. As the armature core is correspondingly constructed there is no mechanical joint in the magnetic circuit. The construction of the motor is in general the same as that which is used for ordinary alternating-current induction motors.

The field coils are wound with copper strap bent on edge, and held firmly in place by adjustable hangers of improved design. The

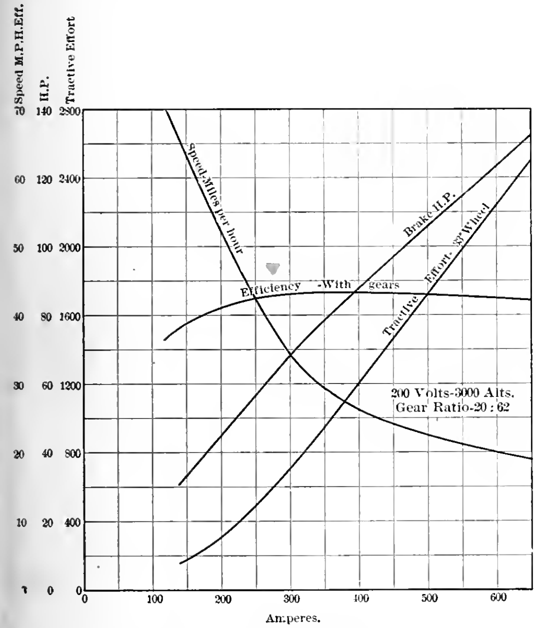

FIG. 4.—PERFORMANCE CURVES.

coils are all connected in series. Brush holders of the sliding shunt type are supported inside the end bracket, and carbon brushes are used.

The armature is of the slotted drum type with machine-formed coils. The core is composed of laminated punchings of soft steel built up upon a spider, with numerous ventilating spaces provided to permit air to circulate through the core and between core and coils. The slots are of the open type. The coils are made of copper strap without joint, and are held in place by retaining wedges of hard fibre, there being no band wires over the core. The winding is of the multiple type. The commutator is built up of cold-rolled copper segments with long necks.

The motor is wound for 225 volts and a frequency of 25 cycles or lower. Its general performance is shown by the curves in Fig. 4. These curves indicate the similarity in performance to the direct-current, series-wound railway motors now standard. Though designed primarily for operation on an alternating-current, single-phase circuit, the motor may also be operated by direct current. For this purpose a modification of the standard controlling apparatus is required.

The motor here described has been designated No. 91. A complete line of motors of this type has been designed by the Westinghouse Electric & Manufacturing Company for application to railway service of any class.

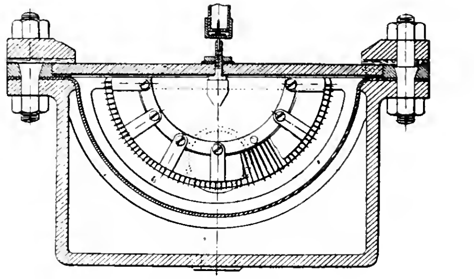
Recent Electrochemical Developments.

STERILIZING WATER BY OZONE.

While in this country that class of electrochemical processes in which chemical effects are produced by electric discharges has been brought into prominence by Bradley's celebrated work on the fixation of nitrogen from air, many inventors abroad have lent their energies to the development of the kindred process of ozonizing air and using the ozone for sterilizing water. On a commercial scale this method seems to have first been applied somewhat over 10 years ago in the city of Hamburg, where, during an epidemic of cholera morbus, smaller ozonizing and water sterilizing apparatus were installed in private residences, which were lighted electrically so that current was available for the other purpose. On a much larger scale such apparatus have been installed more recently in various cities, notably in Diesbaden, where the municipal water works are working in conjunction with an ozonizing plant. In view of the condition of the drinking water in many American cities, it is somewhat singular that such methods have not yet found any introduction in the United States on a commercial scale.

There have been devised quite a number of different ozonizers which vary greatly in design and especially in the nature of the dielectrics. While the Siemens and Halske apparatus, which appears to have found the most extended industrial application, uses glass dielectrics, others do not and are said to work satisfactorily. The use of glass is, of course, always a source of danger since it is liable to break. There is also a great variety in the design of sterilization towers. In general, however, the ozone is introduced at the bottom of the tower, which is filled with stone or sand, while the water passes downwards and thus comes into contact with the rising stream of ozonized air.

A patent granted on February 9 to Mr. A. J. Wessels, of Paris, France, relates to an ozonizer which is similar in design to that of Tindal. As shown in the adjoining illustration, a semi-cylindrical trough of metal, which forms one electrode, is placed inside a jacket of enamel. The intermediate space is filled with water for cooling purposes, since the process of ozonizing air requires that the temperature should not rise above a certain point. A glass cover forms the top of the apparatus and supports a series of metallic points, as shown in the illustration. The electric discharges take place between these points and the semi-cylindrical metallic trough below. The stream of air to be ozonized passes in a direction perpendicular to the cross-section shown in the illustration. The air is passed successively through several ozonizers, between which special cooling devices are inserted to reduce the temperature of the ozonized air, which goes from one ozonizer to the next one.



WESSELS OZONIZER.

MISCELLANEOUS.

A patent granted to Mr. O. Kartzmark, of Brooklyn, relates to details of mechanical construction of an apparatus for purifying liquids. Nothing is said concerning the electrodes to be used nor concerning the chemistry of the process, but it appears that like other inventors he intends to use anodes of such a nature that the anodic products of the current cause subsequent coagulation. In the apparatus described a receptacle with a series of parallel electrodes is placed in a larger vessel. The liquid is passed upwards between the electrodes and flows over the edges of the inner receptacle to the outer vessel.

A patent granted to Mr. A. J. Marschall, of Little Falls, N. Y., refers to the composition of an "exciting liquid" for use in a dry cell. It is a strong solution of zinc chloride with a small addition of ammonium chloride.

New Installation at City of South Norwalk Electric Works.

By A. E. Winchester.

THERE has just been completed an interesting installation, known as "The Enlargement of 1903," at the above plant, which has always been notable for its success. This enlargement is the third one required within five years to meet the increasing demands upon the plant, and is very gratifying to the advocates of municipal ownership. The original plant installed by the city was completed in 1892, at a cost of $22,500, and was used exclusively for street lighting. The movement in favor of the municipal plant was brought about by the poor service for street lighting, supplied by the local company. They supplied the city with 800-cp street lamps, and the demand was for something better. As the company did not respond to the demand, the city plant was built.

The construction and management have been carried on under

FIG. 1.—SOUTH NORWALK STATION.

a Board of Electrical Commissioners, consisting of three members, who were elected by the people from the establishment of the plant in 1892, until 1898, when the arrangement was made to appoint them by the council, which plan is still maintained. The present commissioners are: Mr. J. A. Volk, president; Col. Leslie Smith, treasurer, and Mr. Charles N. Smith, secretary. The plans and specifications of the original plant were prepared by and the construction was executed under the supervision of A. E. Winchester, formerly of the Edison Company, who was one of the electrical commissioners for ten years. He became general superintendent of the plant in 1897, and holds this position at the present time. The first installation consisted of a building containing a boiler, stack, engine, two 60-light arc dynamos, with the necessary switchboard apurtenances, pole line and 86 arc lights. Up to the time of the present enlargement all of the apparatus with the exception of the iron stack have remained in service.

In 1895 the question of embarking in commercial lighting was agitated, and after two years' investigation an appropriation for this purpose of $20,000 was made by the people in 1897. This money enabled the plant to establish a complete commercial service on a paying basis. The growth of the new business was so rapid that a year later it became apparent that it would be necessary to double the output of the commercial branch, and in May, 1900, $17,500 additional appropriation was made available to meet the demand. About this time the Connecticut Lighting & Power Company, which already had instituted suits against the city for alleged damages, etc., on account of the plant, also attempted to prevent the city from supplying commercial lighting or enlarging its plant. An injunction was obtained which was to have been argued before the Supreme Court, but after considerable legal cross fire, which did not stop operation or enlargement, all suits were withdrawn, leaving the city with a clear field to continue the operation of its plant. The city plant does not have a monopoly of the business, as there is a keen though harmonious competition between it and the local company which supplies commercial lighting by means of both electricity and gas; though it confines its energies to promoting the use of the latter. The streets are lighted exclusively by the city plant, which also now supplies over 90 per cent. of the commercial electric lighting and power.

The finances of the municipal plant are managed in a manner similar to that of a private enterprise, the city paying a fixed annual rate of $60 per annum each for the street lamps, and the customers are supplied at 10 cents per kw-hour for lighting and 5 cents for power, as maximum charges, with a sliding scale of prices proportioned to the service used.

Several new enterprises have been attracted to the city by the low rates established for power. In all cases this is lower than it can be made for, by individual customers, and where the installation is of moderate size, the rates are exceedingly low. For a continuous consumption of, say, 50 hp measured by the customers' meters, the rates would be 1.9 cent per hp-hour, corresponding to $4.95 per month, of 26 ten-hour days. There is no place known, except Niagara Falls, where power can be obtained so cheaply and at the same time relieving the manufacturer of the expense and annoyance of operating a power plant. The plant, therefore, enables the people of South Norwalk to enjoy the advantages of lighting and power, 24 hours per day, under most favorable conditions, of excellent quality and at remarkably low rates.

The building, now nearly double its original size, is a substantial brick structure, 48 ft. wide, and 109 ft. long. It has coal house extension with a capacity of 100 tons and is located adjacent to the railroad depot, not far from the center of distribution. In addition to the electric lighting plant, the building contains the city fire alarm system, and the power house whistle is used in connection with the fire bell to sound alarms. The chimney, built in 1898, to replace the original iron stack, is of red brick, built on a natural rock foundation, and in its base is located a fire-proof safe deposit vault for the city records. The "Enlargement of 1903" was decided upon after a careful investigation and report confirming the recommendations of General Superintendent Winchester, made by Prof. George F. Sever, of Columbia University, to a committee appointed by the council. In October, 1902, an appropriation of $20,000 was made to carry out these suggestions. The recommendations advocated the removal of the original belted engine with the two arc dynamos and

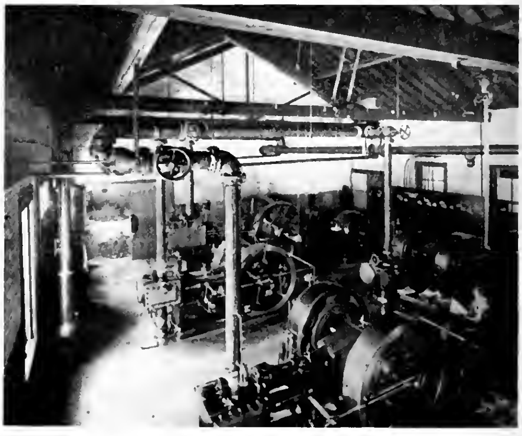


FIG. 2.—VIEW OF INTERIOR OF STATION.

the substitution for these units, of a motor-driven arc machine, capable of supplying 130 enclosed arc lamps, and the installation of a large modern unit to assist in supplying the commercial circuits. The load increased so rapidly that the existing equipment was threatened with serious overloads, until the installation of the new apparatus was completed.

One of the advantages of the new arrangement is that the arc lighting circuits are no longer dependent on any one engine for their operation, as the motor is driven directly from the bus-bars, and any of the five units, operating at 250 volts, has sufficient capacity to operate it. The space occupied by the motor-driven arc unit is so much less than the previous belted arrangement that it was possible also to place the 165-kw direct-connected unit in position without any addition to the building, or changes to the remaining apparatus. Careful records of the load show that this unit is normally sufficient to carry the arc lighting system and a considerable portion of the commercial load without operating the other engines, except at night, during the peak of the load.

The report by Prof. Sever recommended charging for electric current by means of meters, as the business had outgrown the scope of the contract system then in use. The meters have been installed, and their effect on the load curve of the plant is very interesting. The peak becomes sharper and the all-night load is less, showing conclusively that many people were negligent in using current when unnecessary in the old system of flat rates. Another interesting feature is the great demand for 8-cp lamps for residence lighting, in the place of 16-cp. On the whole, the customers appear to be very well satisfied with the meter system, and many find a considerable reduction in their bills over the old rates.

Specifications were prepared by the general superintendent, covering the "enlargement," and after being duly advertised, the conract was let in open competition to Messrs. Bellman & Sanford, of New York City, as general contractors to carry out the work. The motor-driven arc machine consists of a No. 12 four-circuit Brush machine operating at a speed of 500 r.p.m., and connected by means of a flexible coupling to a 90-hp, 8-pole motor. Both of these units were supplied by the General Electric Company, and are mounted upon an oak sub-base to insulate them effectively from the floor. The specifications called for uninterrupted operation of the city lighting system, and the old apparatus was shut down at one o'clock one night, the machinery dismantled, and the new apparatus set up and in working order before six o'clock the evening of the same day. The unit has been in operation uninterruptedly ever since that time, and has given complete satisfaction. The new switchboard panel was built to match the old switchboard, and all the switches were designed to be duplicates of those at present in use. The switchboard work was accomplished in such a manner that there was no interruption to the street service and the clause in the specifications requiring that continuous operation should be maintained was fully carried out, for which Messrs. Bellman & Sanford deserve great credit. After the arc machine was erected, the foundations for the new unit were built the unit erected thereon and the new piping connected to the present mains.

FIG. 3.—THE NEW UNITS.

The large unit consists of a 165-kw, 250-volt Fort Wayne generator, direct-connected to a 20 x 18 Watertown four-valve engine. This unit is mounted on a common sub-base of cast iron that rests upon massive foundations. The generator is guaranteed to carry an overload of 50 per cent. for two hours withut distress, and the engine will drive it under these conditions by slightly increasing the cut-off. The steam economy of this unit operating under full load is guaranteed to be 27 pounds when operating with 90 pounds steam pressure non-condensing. The generator efficiency is 92 per cent. at full load. The combined efficiency of these units is so high that at full load. The combined efficiency of this unit is so high that it is effecting a considerable saving in the operating expenses of the plant over the three small units which it supplements.

The design of the plant arranged for two steam mains cross-connected. By closing proper valves, it was possible to erect the new piping without interfering with the operation of the plant. Extra heavy piping was used throughout and the joints made up with 1/16-in. rubber packing. The pipe covering used was a combination of asbestos and cork, neatly covered with canvas and painted to match the other piping.

The old type open arc street lamps were replaced with modern enclosed arc lamps, which operate on a 5-amp series current. These lamps are manufactured by the Fort Wayne Electric Company. The cases are of sheet copper, and entirely water and bug proof. The former attribute is very necessary owing to the heavy fogs and storms along the coast. The efficiency of these lamps is greater than the old type and the diffusion of the light by the inner globe makes them more satisfactory to the city. The result of the better illumination is at once apparent on the streets.

After the installation of the machinery was finished, a test run of one week was made, to show that it fully complied with all of the specifications. It was then painted and striped to match the remainder of the machinery in the power house, and all the work left completed to the satisfaction of the general superintendent, and reflects most favorably on the skill and expertness of the contractors.

The results of the change and the improved machinery are already apparent in the economy of operation. Where it was previously necessary to operate four boilers, on the peak load, from two to three carry it now without difficulty. The average saving is nearly a ton of coal per day. This great saving is due to the higher efficiency of the new engine and the greater economy of the motor-driven arc machine. In addition to this, there is a considerable saving in the labor of trimming the lamps, as the new lamps burn 100 hours at a trim, compared with the old ones, which burned only 14 hours.

The plant to-day is thoroughly modern, inventorying about $88,000, of which about $16,000 has been paid from profits. Its normal capacity is 700 hp, supplying 108 street arc lamps, a commercial load of between 6,000 and 7,000 16-cp lamps connected and electric power for 26 manufacturing concerns.

FIG. 4.—VIEW OF SWITCHBOARD.

During the eleven years' existence of the plant it has saved the city in the item of street lighting alone, including all operating expenses, interest, depreciation, etc., over $27,500 as the difference between the average rate of the State, and what the cost has been from the city plant. As the original cost to establish the street lighting system was $22,500, the saving has not only paid for the plant, but leaves a net balance of $5,000 to the good. Aside from this, the commercial income yields an annual profit varying from $3,000 to $5,000, which is used to reduce the debt, and in time, under favorable conditions, as judged by the past results, will eventually free the plant of debt.

Probably one of the greatest, if not the greatest, factor in the success of this municipal enterprise may be traced to its independence from politics, which never have had any voice in its management or appointments, and the fact that it is operated to all intents without dictation from the local government.

The Recent Great Fire in Baltimore.

FIG. 1.—ELECTRIC LIGHT POLE.

THE great fire in Baltimore, which, breaking out on Sunday morning, February 7, destroyed probably $100,000,000 in property in the space of 48 hours, has already had its main features made known to every one who reads the daily newspapers. It has also been profusely illustrated from pretty well every point of view. It is not necessary, therefore, that in referring to the electrical conditions there we should repeat that which has already been covered almost *ad nauseam*. As has already been mentioned, the telegraph, telephone, electric light and street railway services suffered severely and their financial loss was considerable; although the interruption to service was remarkably short owing to the energy displayed by the officials of the various companies. We are glad to be able, however, to to present a few views of the devastation from some snapshots taken by Mr. Douglass Burnett, formerly of the New York Edison system, who has but recently become general manager of the United Electric Light & Power Company, of Baltimore, and who, in fact, may be said to have received thus his "baptism of fire" on being inducted into his new position.

The snapshots shown are some of those taken February 8 and 9 in the burned district, one of them, Fig. 2, looking north on Charles Street from the corner of Baltimore Street toward the Union Trust Building. It shows the overhead wires, which, curiously enough, were to have been abandoned upon the opening of the subway system on February 10. Invitations were to have been mailed on the Monday morning, the day after the fire, for the opening of the new rotary station on McClellan Street. The opening was to have taken place on Wednesday afternoon at 3.30, when the United Company expected to turn current on to the new underground, three-wire, direct-current system. Fig. 4 shows the new McClellan Street station, which had a most fortunate escape, the only damage being the breakage of the windows through the falling of neighboring walls. Fig. 5 shows the rotaries, transformers, etc., in this station after the fire. The building is surrounded by walls of gutted buildings in every direction, but the management has noted no damage was done to it except where the wire glass was cracked by the heat and where some of the sashes were broken by falling walls and bricks.

The United Company's men received the first fire signal when the automatic alarm in the Hurst Building not far away went off, and several of them went immediately to the premises, arriving when the first explosion occurred. Mr. Burnett himself saw personally the first flames burst from the building and was on his way to it and within two blocks of it at the time of the explosion. He and his men were thus on the ground from the very beginning of the fire. The service was shut down as soon as practicable, but the city lighting was resumed a few minutes after dusk in all but the burned territory; and the power circuits were in operation next morning. The McClellan Street station and the Pratt Street railway power house, both of which stood up so wonderfully while in the thick of this

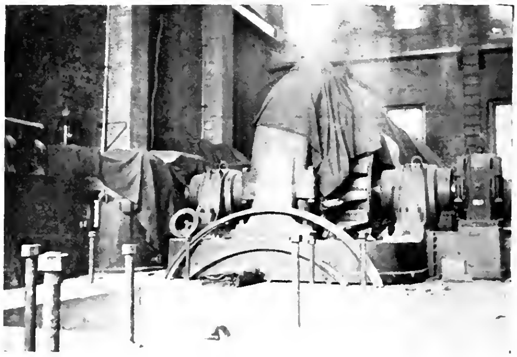

FIG. 5.—INTERIOR OF STATION.

unexpected fire, were designed by Mr. P. O. Keilholtz, consulting engineer of the company. In all probability Mr. Keilholtz did not have the remotest idea that his work would ever be subjected to such a test and strain as this; but he would wish no better example of endurance in design and equipment than was afforded at both places. It still remains a wonder that both plants were not wiped out of existence, and central station men might doubtless do worse than study the features of construction embodied in the stations named. As we understand it, the fire would have destroyed Pratt Street had the material there afforded the least encouragement.

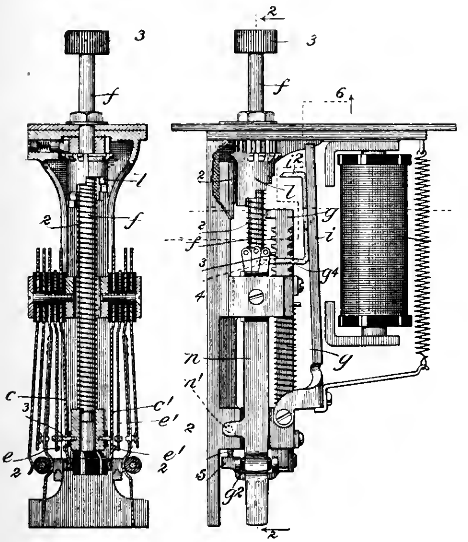
It is a remarkable fact that while 30 city arc lamps on a rough estimate were in the burned district, a number of them were in place or could be readily renewed. One of the views herewith, Fig. 1, shows one of the several city arc lamps in the district with the globes, lamp and the shepherd's crook intact, the wooden post being partially burned away. Another view, Fig. 3, shows the Hotel Carrollton on the left; the Continental Trust Building in the middle distance, where the Postal Telegraph Company's headquarters were wiped out, and the Maryland Trust Building on the right. The fire alarm box can be seen in the foreground. As usual, it was one of the curiosities of the fire to notice what was destroyed and what by some inexplicable chance was left standing and almost unharmed.

FIGS. 2, 3 AND 4.—VIEWS OF THE BURNED DISTRICT.

New Telephone Patents.

CODE-RINGING KEY.

Probably the most extraordinary ringing key of recent years is one for automatically giving code signals on non-selective party lines, which has recently been invented. With such a key it is aimed to overcome the drag upon the operator occasioned by the time and care necessary to send clear and distinct signals. Incidentally, at least one source of annoyance to subscribers is removed. This results from the fact that an indicator serves to show what code was last sent out on the key and the operator may repeat it in case of failure of the called party to answer without the necessity of questioning the calling party as to the station desired before an additional signal may be sent. A side view of the key as developed is shown in Fig. 1, together with a sectional view which shows the arrangement of springs. What may be called the key to the situation is, however, not shown, being an interrupter continuously driven, and included in the current leads which supply the keys. This interrupter times the interval between, and the duration of, the component rings which form the signal. It consists of two elements —that which controls the ringing current and that which controls a direct-current circuit, which restores the key to normal after the completion of the desired signal. These are so mounted upon their common shaft that the angular position of a dead segment of one corresponds exactly with that of a live segment of the other; that is



SCRIBNER-M'BERTY RINGING KEY.

to say, that while the restoring current is being supplied the ringing current is cut off and vise versa. The operation of the key is effected from a single button, which has two motions—a rotative one about its spindle as an axis, and a vertical one. The process of sending a signal first requires that the button be rotated until a pointer traveling with it indicates the desired party number upon a dial formed upon the key face. There is also traveling with the key spindle a stepped collar, *l*. This engages the ratchet bar, *g*, and the ultimate depression of the ratchet bar is dependent solely upon which step of the collar is in position to engage the bar. Ten-party lines are evidently contemplated, the bells of five stations being on each side of the line, the return circuit being earthed. Therefore, a switching device must be provided to connect the generator to the desired side of the line. This comprises the two sets of springs next the plunger, marked *C e'* and *C'e'*, together with the cam wedge of hard rubber secured to the end of the push spindle. This cam is so shaped that when turned to the right it affects one pair of springs, so that the ring is on one side of the line, and if turned to the left the other side of the line will be rung upon.

As soon as the key has been set and the depression begins, the supply of ringing current is temporarily cut off. Next the ratchet bar becomes engaged and depressed. This affects the ringing key proper, this embracing the outer sets of springs. However, no signals are sent as the current supply is cut off until the plunger returns to the uppermost position. This it strives to do as soon as released; but it only succeeds in doing it at a time when the interrupter is on a segment corresponding to silence of the bells, as its motion is restrained by the dog i_2, except when the armature *i* is pulled up. If this provision were not made the first ring might be of irregular duration. When the plunger has returned home and closed the ringing supply to the key, the code ringing begins, following the commutator; at each silent period the wedge of the ringing springs returns one step toward the normal position, being stepped along by the detent vibrating by the restoring magnet, as this receives direct curreent from the commutator during the silent periods. When the normal is finally reached the ringing springs become released by the wedge rolls dropping into their grooves. Just as this occurs a small pawl which has been restraining the plunger from being depressed during the automatic operations, is tilted to free the spindle for a further signal, should this be found necessary. Two patents have been granted for this key, both assigned to the Western Electric Company. C. E. Scribner has obtained one of these, while Frank R. McBerty has been granted the other one.

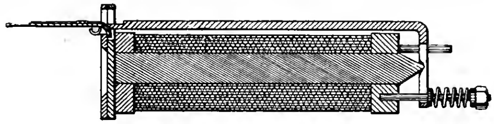
HAND TELEPHONES.

Two patents have been granted for designs of hand telephone apparatus. One of these describes a receiver of the general outward appearance of the old Bell hand telephone. The novel features, however, are several in number. First of all, the diaphragm is given an initial tension by an annular spring, which is forced upon it by the receiver cap. This bows the diaphragm toward the magnet pole. Second, the diaphragm is provided with a pole piece. This enters the end of the coil spool, the magnet being cut short to permit of this. The combined result, the inventor, Mr. Ernest Gundlach, of Western Springs, Ill., states, is an increased efficiency.

The second hand telephone combines a transmitter, a receiver and a calling buzzer within one piece of apparatus, the whole being assembled after the manner of the hand microphone of foreign practice. The calling device is contained within the receiver casing and consists of a buzzer, the magnet of which is that of the receiver. A switch upon the handle of the apparatus effects the transfer of circuits to the talking or calling conditions, as described. The whole forms a compact instrument apparently fairly well suited to the interior or house system working for which it is designed. Mr. E. T. Billig, of New York City, has obtained the patent covering this apparatus.

DIRECT-CURRENT DROP.

Fig. 2 shows a rather neat direct-current line drop which has recently been invented by Lambert Schmidt, of Weehawken, N. J. The



SCHMIDT ANNUNCIATOR.

magnetic circuit is very well designed, the air-gap being extremely small. The use of the core as a knife edge for the swinging armature is commendable, resulting in extreme simplicity of construction. The operation of the drop will be evident at a glance.

CENTRAL ENERGY SYSTEM.

A central energy system in which two repeating coils are used in each cord circuit forms the subject of a patent obtained by J. H. Lendi, of Chicago, and assigned to the Kellogg Switchboard & Supply Company. The object of using two repeating coils is that by so doing each can serve an additional function—as the winding of a supervisory relay. One winding of each coil is included in the battery supply circuit of one subscriber, while the other winding has a condenser inserted in circuit. In using the coils the condenser section of one is placed in parallel with the battery section of the other. Thus the relay armature associated with each coil responds only to the proper subscriber, while the inductive relations of the two ends of the cord circuit are such as to warrant good transmission.

SEMI-AUTOMATIC SWITCHBOARD SYSTEM.

What may be called a semi-automatic system has been invented by J. Kitsee, of Philadelphia. In this system a continuously revolving selector connects the operator to calling subscriber one by one in the order of the origination of their calls. The selector is stopped each time a call is found until the connecting plugs have been inserted in the jacks. Then the selector starts the process of locating and connecting the operator to the next call. This scheme does not seem very practical and, therefore, detailed explanation is omitted.

SOUND INTENSIFIER.

Mr. Gustaf T. Swenson, of San Pedro, Cal., has added to the applications of the telephone as a receiver for wireless telegraph signals. He arranges two electromagnets and a battery as a shunt upon the coherer, and by this means the received signals vary the magnetization of the magnets. These latter affect respectively the two diaphragms of a sort of receiver microphone repeater, which in turn affects a telephone receiver. Of course, no questions of timbre or quality are involved, great volume of sound in proportion to the received energy being alone desired.

Ohio Independent Telephone Companies.

A meeting of the independent telephone companies of Ohio will be held in Cincinnati, February 17, 18 and 19. The purpose of the meeting is to discuss closer association among the Ohio independent companies. The Independent Telephone Traffic Association of Cleveland is back of the movement. Several weeks ago a meeting was held in Columbus with the same aims in view and a committee was appointed to take up the question. One of the chief aims of the Cincinnati meeting will be the formation of a State association to take the place of the present association, which is now practically disrupted. Following the formation of an Ohio association it is the aim to form an inter-state association to combine similar associations in several of the central states. The purpose of holding the meeting in Cincinnati is to give encouragement to the independent companies that are now working to secure admission to Cincinnati; also to demonstrate the strength of the independent move in Ohio.

A Trade Mark Decision.

Judge Brown, of the Circuit Court of the United States, District of Massachusetts, has handed down an opinion enjoining a company which renews incandescent lamps from retaining the letters "G. E." in the stems of lamps renewed. The gist of the opinion is that this trade-mark is practically removable in the remaking of lamps, since it can be obliterated at an expense of only 55 cents per thousand lamps by applying to the exterior of the stem and over the trade-mark a small quantity of chemical paste. Since the bulb is opened on remaking to insert new filaments and to fasten them to the ends of the leading-in wires with carbon paste, the application of the same paste for the obliteration of the trade-mark the court held to be an obvious expedient. The opinion states that there is strong evidence that the real purpose in affixing an indelible trade-mark was for the ordinary purpose of a trade-mark and not, as the defendants alleged, as a part of a scheme to attack its business of remaking lamps. In summing up the court says that the complainant has a valid trade-mark. The defendants without legal justification put forth lamps bearing on this trade-mark. Though they did so without any intent to deceive and have been honorable in intention and in their business methods, and so far as appears have caused no actual deception, yet the use of this trade-mark in violation of its legal rights entitles the complainant to an injunction.

Independent Telephones in Post-Offices.

A special dispatch from Cleveland, O., of February 13 says: "Frederick S. Dickson, president of the Cuyahoga Telephone Company here, has won his fight against President Roosevelt and Postmaster-General Payne. The latter, with the President's sanction, ruled that post-offices throughout the country should use only one telephone, viz.: the one that had long-distance connection with Washington. This meant the loss of a large sum to the independent telephone interests of the country. Dickson pleaded with Mr. Roosevelt to intercede, but without success. But through many Senators and Representatives he has succeeded in getting the Payne ruling modified so that the independents will have a chance.

CURRENT NEWS AND NOTES.

MICA MINES in Charleroix County, Quebec, are mentioned as places where minerals are obtainable with remarkable radioactive qualities.

TROLLEYS IN NEW HAMPSHIRE.—The electric and traction street car companies in New Hampshire, of which there are eighteen, made a disappointing showing during the last year, according to the annual report of the State Railroad Commissioners. The Manchester Street Railway was the only one which earned a dividend. The street railroads in the State have 228 miles of track, $3,552,119 stock, $2,066,000 in bonds, and $1,109,003 liabilities. The gross income was $834,894; operating expenses, $796,795; taxes and interest, $103,250, and a deficit of $65,161. The Manchester road had a divisible income of $31,807.

FREEZING OUT A LEAK.—An interesting piece of engineering was recently carried out in St. Louis. A leak occurred in one of the cofferdams being used in the construction of the foundations for the new plant of the Union Electric Company on the river front. Water from the river poured through the leak and it looked as if serious damage would result. Finally the mechanical engineer of a near-by refrigerating plant met the situation by freezing out the leak. He laid ammonia pipes from his plant to the point where the leak existed and the breach was soon closed with solid ice. The water was then pumped out and work resumed.

STEAM AND TELEGRAPH.—Echoing the sentiment and ideas of Maud Müller, the London *Daily Telegraph* discusses the recent Pilgrim dinners in London and New York, conducted simultaneously by cable, and says: "Picturesque and genial as the event was in itself, and appealing with singular success, as it does, to the spirit of friendly good humor which, happily, is the dominating factor in the intercourse between the British and American peoples to-day, it has a profound meaning, whereof serious historians of the future may well take account. The nations in spite of themselves are being knitted together by the conditions of modern intercourse and the spirit of modern science in a mesh of subtle, invisible strands which is morally as strong as hoops of steel. If steam and telegraph, for instance, had existed in the latter half of the eighteenth century it is certain that the separation of the race would never have taken place."

SALE OF FRANCHISES.—Assemblyman Finch, of New York, has introduced in the New York Legislature a concurrent resolution amending the State Constitution with regard to the disposal of franchises to public service corporations. The proposed amendment was one which would absolutely forbid the giving away of any franchise or public utility, and compel the same to be sold at public auction. In the charter of the City of New York and the charters of second-class cities this is already provided for. But the significant thing in the resolution, so far as New York City was concerned, is a provision compelling the resale of franchises at public auction every fifty years, thus compelling the street railway companies, gas companies, telephone and telegraph companies, and all other public service corporations to repurchase their franchises from the city after they have enjoyed them for a fifty-year period.

MAGNETIC STEEL.—Mr. Robert A. Hadfield, vice-president of the British Iron and Steel Institute, has taken out an American patent under date of December 1, 1903, which covers the results obtained in the now classical papers of Barrett, Brown and Hadfield, first published in the *Proceedings* of the Royal Dublin Society and later in the *Journal* of the English Institution of Electrical Engineers. From this patent it appears that the heat treatment which Mr. Hadfield gives steel, either in castings or transformer plate, is quite as important as the original crucible charges from which the steel is made. It is rather startling to have perhaps the first living authority on the practical heat treatment of special steels announce that by an ingenious use of heat treatment and composition combined, he has succeeded in producing a magnetic material showing a magnetic permeability higher, and a hysteresis action lower, than the purest iron commercially obtainable.

ELECTRIC AUTOMOBILE SPEED.—In the recent automobile contests at Ormond Beach, Fla., the speed record for electric machines was lowered by Mr. W. J. Hastings on the Baker torpedo "Kid" with a mile in 1:00⅘ min., and the kilometer in 0:37⅗ sec.

ELECTRIC POWER ON NEW YORK CENTRAL.—The New York Central Railroad Company has, according to to a dispatch from Yonkers, N. Y., promised to build a large power house in that city at a cost of $2,500,000. It has laid before the Mayor and Aldermen plans to eliminate all grade crossings in the city preparatory to the introduction of the third-rail system. The plan approved will be submitted to the Legislature for final action. It is stated that the plans contemplate the use of five tracks to Croton.

PARIS TROLLEYS AND CABS.—A cable dispatch from Paris says that the Paris cabman is being threatened with loss of patronage and power by the slowly-increasing improvements in urban transportation facilities, notably in the instance of the Metropolitan underground system, with its three- sou (three-cent) fares. The cabman's syndicate is considering a project of reducing single fares so that the first 400 meters (quarter of a mile) be paid at a minimum rate of seventy centimes (fourteen cents), and also of attaching an automatic distance indicator, the same as that used in Berlin and Vienna.

RADIUM AND CANCER.—A cable dispatch from Vienna of January 28th says: "Professor Gussenbauer, an eminent surgeon, has discovered that contraction of the gullet caused by cancer can be alleviated in certain cases by the use of radium. The experiment was made of applying sixty milligrammes of radium in a rubber capsule to the affected part. The radium rays decomposed the cancerous growth, enlarging the gullet and allowing food to be swallowed, thus obviating an operation for the introduction of food into the stomach. The experiment is somewhat dangerous until further knowledge is obtained, inasmuch as too much radium will decompose the ulcer so rapidly that there is risk of perforating the gullet."

TRADE-MARK PROTECTION.—Many of our readers are interested in an appeal that has been sent out for support of national legislation for trade-mark protection. It is believed to be very desirable, and essential to place trade-marks on an interstate footing, and bring all trade-marks used in "commerce among the several States" under Federal statutory protection. The bill introduced by Senator Stewart January 12, 1904 (Senate Bill 3353), is intended to extend to trade-marks used in interstate commerce the statutory rights and privileges accorded to trade-marks used in foreign or Indian commerce. This bill provides also for a bureau, at the head of which shall be a Register of Commercial Marks, appointed by the President, at a salary of $3,000 a year.

BEARING OIL IN INDIA.—An article in the *World's Work* for February says: "When the American Engineers were building an electric power station in the Mysore territory in Southern India they found that something was wrong with the lubrication of the machinery. The oil disappeared. They discovered that a Hindu must, by his religion, take a periodical bath in oil. To him oil is oil. The workmen had drained the bearings for bathing purposes. How to stop the thieving was a puzzling problem until some one solved it. The Hindu does not eat meat, and he will not touch anything that has blood in it. Two or three animals were killed, therefore, and blood was dripped into the bearings. There was no more stealing of oil; however many other things were stolen."

FREE TELEPHONE SERVICE IN CHICAGO.—The Illinois Tunnel Company, which operates the new automatic telephone exchange in the business district of Chicago, gave notice to its subscribers February 5 that all service would be free up to April 1, 1904, and that all charges for past service would be canceled. The object is to educate the public up to using the new automatic service. So far the automatic telephone has not been used as much as it might have been had it not been on a strictly measured rate of 5 cents per call, whereas many of the Chicago Telephone Company's instruments are on a flat rate and others are on a guaranteed minimum rate for measured service; so that the automatic telephone would only be used when the old telephone was busy, or especially quick connection was desired.

INSTITUTE BUILDING FUND.—The Building Fund Committee of the American Institute of Electrical Engineers has taken hold very vigorously of its work of raising funds from among the members primarily, and next from electrical concerns benefited by engineering progress. It has just addressed circulars to all the membership, from which it has already raised considerably over $30,000, some sums being promised in a lump and others spread out over a term of five years. The committee hopes to secure practically the name of every member on this subscription list, and is greatly encouraged by the hearty and public-spirited responses it is receiving from all over the country. A careful and elaborate plan of campaign, to which we shall again have occasion to refer, is being inaugurated and is to be persistently pushed.

A. I. E. E. PHILADELPHIA LOCAL MEETING.—At a meeting of the Philadelphia Branch of the American Institute of Electrical Engineers, at the Engineers' Club, of Philadelphia, on the evening of February 8, Mr. C. E. Bonine gave a talk on the "Principles of Alternating-Current Motors," which was followed by an abstract by Mr. E. P. Coles of Mr. Walter I. Slichter's paper on "Speed-Torque Characteristics of the Single-Phase Repulsion Motor," and Mr. Charles P. Steinmetz's paper on "The Alternating-Current Railway Motor," which were presented at the New York meeting. Mr. C. E. Renshaw, of the Westinghouse Company, Pittsburg, gave a paper on "Alternating-Current Railway Motors." Mr. Renshaw dwelt upon the many advantages the alternating-current motor has over the direct for railway purposes, and went into details as to the principles governing the single-phase alternating-current motor. The discussion was participated in by Messrs. Cutler, Thomas Spencer and Breed.

WIRELESS IN BRAZIL.—Mr. K. K. Kenneday, United States Consul at Para, Brazil, writing recently says: "Experiments with a wireless telegraph system which have been quietly carried on between Manaos and Iquitos during the past few months have shown such satisfactory results that the cable company has bought the right to use the system between Para and Manaos, and the manager of the Manaos office is now in Para making final arrangements for installing the system. No other improvement is so important to the commercial interests of the Amazon Valley as the installment of a reliable telegraph service between Para, Manaos and upriver points. Owing to the character of the country through which it must pass a land line is impossible, and it has been found equally impossible to keep a cable line in steady operation. The present cable, recently laid and maintained at an enormous expense, is rarely in working order more than one or two days per week. The rapid and violent fluctuations of exchange in this country render it almost vital for merchants, shippers and brokers to keep in close and uninterrupted touch with their branch houses and agents at all points, and the constant breakages of the cable are looked upon as a calamity."

STATE GUARD ELECTRICIANS.—A bill is before the New York Assembly providing for enlistment of five technical expert civilian electricians as engineers of heavy artillery National Guard State of New York, for service in coast defenses, has been introduced and passed in the lower house with a fair chance, if pushed, of passing the State Senate and becoming a law. This bill, as we understand it, is the outgrowth of articles published a year or more ago in Electrical World and Engineer and was proposed or endorsed by members of the American Institute of Electrical Engineers, who took up the subject of having the National Guards of Massachusetts, Connecticut and this State (the only ones with heavy artillery organization), employ, with sergeant's rank, technical electrical engineers from civil life to handle coast defense plants such as are used in practice drills at Willets Point, Fort Totten and other coast defense points. We published several articles about it and described the manœuvres and experiments, at Fort Terry, of a volunteer engineer, Sergeant M. C. Sullivan, of one of the Thirteenth Regiment's companies, who gave a demonstration at the Military Tournament last year, in Madison Square Garden. We understand Col. Austin, of the Thirteenth, and Capt. Taylor, of the same regiment, are deeply interested in this bill.

Letter to the Editors.

Radium and Helium.

To the Editors of Electrical World and Engineer:

Sirs:—Considering the intense interest manifested in the marvelous performances of radium and kindred substances, would it be proper and permissible for a layman to put in a word on the subject?

Two statements recently made seem suggestive of a probable solution of the problem. The one is that radium maintains a higher temperature than its surroundings, the other that the emanated matter is helium. Does not this indicate that the phenomenon must be supposed analogous to what is commonly called combustion? This would, of course, imply that helium is a compound, not an element, but is there anything impossible in that? A piece of charcoal, for instance, at red heat, exposed to oxygen mixed or combined with other matter, will issue carbonic acid or other gases as the case may be—whether with or without measurable wave lengths I don't know. But the process will keep the temperature of the coal above that of its surroundings and the expelled—emanated—gases will give off their heat to whatever they strike and remain gaseous until a very low temperature is reached, exactly as in the case of radium. That the gases are expelled at a greater rate of quantity and a smaller rate of speed than the helium, does not alter the apparent similarity of the process.

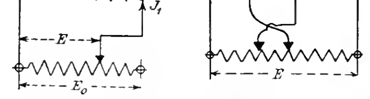
But this surmise would also imply that radium diminished in quantity by the so-called radiation. Perhaps it does, unless something is added to it from a source unknown. There would still be room for much interesting research, and more wonders may yet be found in connection with it.

Chicago, Ill. S. T. Sue.

DIGEST OF CURRENT ELECTRICAL LITERATURE.

Dynamos, Motors and Transformers.

Single Phase Commutator Motor.—Eichberg.—A very long paper, illustrated by a great many diagrams, on single phase commutator and their regulation. The author first discusses in general the phenomena which are of importance in a commutator motor and gives a review of the properties of the ordinary series motor and repulsion motor and deals finally with the Eichberg-Winter motor. Its arrangement is diagramatically shown in Fig. 1. Both the exciting voltage e and the total voltage E can be adjusted, although in high voltage motors the regulation of E would be inconvenient. The motor has a single phase stator winding and a rotor which is absolutely identical with a direct-current armature. The rotor winding is used in a double way. In one axis it is short-circuited so that it may be considered to form a short-circuit winding $W_{11}{}^1$ for the stator winding W_1. In points (brushes $b\,b$) which have the same potential as the short-circuited brushes $B\,B$, the exciting currents are introduced. It would, of course, be just as well possible to provide two separate commutator windings. With a two-pole arrangement it is necessary to use four brushes. With $2p$-pole series windings or parallel winding with Mordey connections, four brushes are also required; in the most general case $2p$ short-circuit and $2p$ exciting brushes may be used. The exciting current i itself is furnished by an adjustable series motor (or potential regulator). It is therefore always in phase with the primary current J_1. During



Figs. 1 and 2.—Single-Phase Commutator Motor.

starting, $W_{11}{}^1$ is essentially a short-circuited transformer which represents a relatively small impedance. With increasing speed, there is produced in $W_{11}{}^1$ (between the brushes $B\,B$) an e.m.f. in phase with i or J_1. The windings $W_1\,W_{11}{}^1$ therefore form together with increasing speed a transformer with an ohmic resistance load. In accordance with the increase of this load with increasing speed, the field Φ increases. The secondary circuit of the series transformer represents in the first moment a relatively high impedance. The less secondary turns are connected to the exciting circuit $b\,b$, the greater is the impedance of the series transformer. During starting, a very large part of the total voltage will be consumed by the transformer. With increasing speed, there will be produced between the brushes $b\,b$ an e.m.f. in phase with Φ. This annihilates the self-induction in the exciting circuit, and at a sufficiently high speed the secondary of the transformer will possess only a very small voltage, corresponding to the ohmic loss in the winding and the slot leakage. The total voltage E resolves itself during starting in such a way that W_1 gets a small pressure which, however, increases with increasing speed and soon reaches nearly the full value, E. The presence of the "cross field" Φ makes it possible to annihilate the short-circuit e.m.f. simultaneously with the annihilation of the inductance of the excitation winding. By varying the transformation ratio it is possible to adjust the ratio of F to Φ. Stator and rotor winding are independent of each other. It is therefore possible to apply directly a high voltage. In spite of the use of only one stator winding, the motor can be reversed, even without opening the stator circuit. If the secondary number of turns is increased, we get a higher speed for the same torque or a higher torque for the same speed. One may therefore start, without varying the primary voltage, simply by increasing the number of secondary turns. By this arangement it is possible to start, reverse, and stop the motor, without interrupting the high tension circuit. The curves obtained by the motor have already been reproduced and discussed in these columns. It is possible to arrange the motor so that it starts with full torque and maintains a given speed. The voltage at the exciting circuit and at the stator has approximately the same phase for nearly all speeds. It is therefore possible to get the voltage for the exciting circuit and the stator from the same transformer, the stator voltage being increased and the exciting voltage being diminished with increasing speed. Near synchronism only a few volts are used for excitation. Fig. 2 shows the arrangement which the author believes to be specially suitable for elevators and machine tool driving. The author sums up as follows what he considers to be the essential accomplishments of his system: The production and independent adjustment of the two fields, F and Φ in Fig. 1, results in the annihilation of the short circuit energy below the brushes and of the phase difference of the motor within wide limits. It is further possible to change the characteristic curve of the motor with constant total voltage (of the supply network), or, in other words, to get any torque at any speed. For high-tension motors it is possible to start, reverse and stop the motor, without opening the primary circuit. The motor has all good properties of the direct-current traction motor, among them the good action of commutator and brushes.—*Elek. Zeit.*, January 28.

Magnetic Dispersion in Induction Motors.—Behn-Eschenburg.—

An abstract of a paper read before the British Inst. Elec. Eng. The dispersion coefficient is defined as unity minus the ratio of the product of the coefficients of mutual induction to the product of the coefficients of self-induction of the primary and secondary windings respectively. It may be obtained experimentally as the ratio of the magnetizing current to the short-circuit current at equal terminal potential differences. It may be regarded as the sum of three distinct coefficients; first, the winding coefficient; secondly, the peripheral disperson; third, the flank dispersion. Concerning the first coefficient he says that in every motor a difference exists between the self-induction of the winding of one system and the mutual induction between corresponding portions of the windings of the primary and secondary systems, even if there were no so-called magnetic leakage to influence the relation. The reason is that mutual induction is the sum of the products of the magnetic lines by the number of conductors interlinked by each. Even if no magnetic line produced by the primary current fails to interlink with the secondary circuit, the number of times it interlinks the secondary turns depends upon the relative positions of the two circuits. There will be a relative position giving the maximum mutual induction, and one giving a minimum, and since one position is obtained from the other by steady motion, the average value will be the arithmetic mean of the maximum and minimum values. The winding coefficient is defined as half the difference beetween the maximum and minimum values divided by the maximum value. This coefficient is less the larger number of slots of the primary on the one hand or of the secondary on the other. In every motor, however, there come into operation magnetic leakages which may be separated into two stray fluxes so that we may distinguish between peripheral dispersion and flank dispersion. Peripheral dispersion runs along the face of the bore of the stator and along the phase of the cylindrical periphery of the rotor, since between the tops of the iron teeth of each single system over the openings of the slots there occurs a leakage of magnetic lines. These stray fluxes along the peripheral surfaces will bear to the mean total flux the same proportion as the magnetic reluctance of the path followed by the mean total flux bears to the magnetic reluctance interposed in the path of the stray magnetic flux between the tops of the teeth. The quotient of the stray flux by the main flux is called the peripheral dispersion coefficient. The second kind of magnetic leakage, called flank dispersion, exists outside the iron core. Those parts of the winding which constitute the end connections between conductors in the slots, and which project as curved winding bunches or bends at the flanks of the stator and rotor cylinders, give rise to a magnetic flux outside the iron core bodies. In the main this stray flux is equal to the magnetic flux

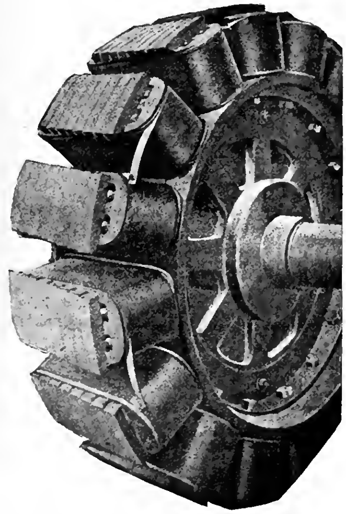


FIG. 3.—POLE CONSTRUCTION OF ALTERNATOR.

which would be created by an independent group of coils of a form similar to the two projecting bends at the two flanks, if put together as a coil. The author gives approximate formulas for calculating these three coefficients and by adding them he gets the total dispersion coefficient. He thinks that this coefficient may well form the basis upon which to design induction motors as upon it depends the power factor.—Lond. *Elec. Rev.*, January 29.—An illustrated reprint in full of the paper begins in Lond. *Elec.*, January 22.

Alternators Giving a Pure Sinusoidal e.m.f.—PATERSON.—A fully illustrated article in which it is said that the Oerlikon Company built the generators for the Lauffen transmission in 1891 with their pole pieces set at an angle to the axis of the pole wheel, with the result that the wave of electromotive force was very nearly a sine curve. The same firm is now building generators on this principle, and Fig. 3 shows the special pole construction. The iron is laminated throughout, the stamping being arranged in such a way that the polar edge makes an angle with the axis of the wheel. The distribution of flux with relation to the stator conductors tends to produce the desired effect.—Lond. *Elec. Rev.*, January 29.

REFERENCES.

Auxiliary Poles for Direct-Current Machines.—PUNGA.—An article referring to the paper of Pichelmayer who, as was recently noticed in the Digest, recommends the use of auxiliary poles for generating a special commutating field in order to insure perfect commutation. The present author remarks that such auxiliary poles have repeatedly been suggested before, but their use has distinct practical disadvantages which make the design difficult. Compared with the normal direct-current machine, a machine provided with auxiliary poles is more expensive. The use of auxiliary poles will be only justified when the voltage and the speed are comparatively high so that the design of a normal machine would become impossible, for instance, in the case of a 500-kw machine running at 1,000 revolutions per minute. In connection with steam turbines the use of auxiliary poles should be in place.—*Zeit. f. Elek.* (Vienna), January 24.

LIGHTS AND LIGHTING.

Three Phase Arc.—MERCANTON.—An account of experiments which he has made with a three-phase are, using three carbons arranged symmetrically and inclined to each other so as to form a triangular pyramid. The results depend to some extent upon the nature of the carbons used. The carbons should contain substances capable of volatilizing and "nourishing" the arc. Fig. 4 shows the

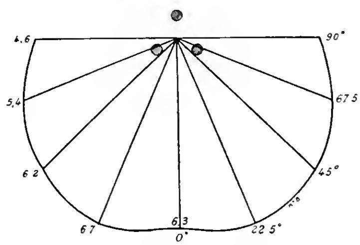

FIG. 4.—THREE-PHASE ARC.

results of photometric measurements with one set of such carbons, the lengths of the radii representing the candles per watt so that for 0° one watt gives 6.3 candles or reversely 0.160 watt is consumed per candle, which is a rather good efficiency. In spite of the advantages of the three-phase arc he thinks that mechanical complications would prevent its introduction into general use, but for special uses where regulation by hand is possible, and especially in connection with searchlights, the three-phase arc is thought to be able to render important service, on account of its steadiness and high light effect.—*L'Eclairage Elec.*, January 30.

Triplex Lamps.—HOPPE.—The first part of an article in which the author discusses the result which have been obtained in practice with the connection of three 35 to 37-volt arc lamps in series across 110-volt mains or of six such lamps in series across 220-volt mains. The advantage gained is that no energy is wasted in series resistances (as is the case with two 42 to 46 lamps in series across 110-volt mains). But on account of the series resistance being avoided, certain conditions must be vigorously fulfilled, if the light shall be good and steady. The regulating devices must be absolutely exact and in good working order, the best material must be used for the carbons, and there must not be any large variations of the voltage of the mains. Moreover, these lamps need special attendance, and if one lamp comes out of order, a comparatively large number of others is involved. The article is to be concluded. In the conclusion the author proposes to discuss the question of cost.—*Elek. Anz.*, January 24.

REFERENCES.

Lighting.—Lummer.—The first part of an article in which the author emphasizes that in spite of the enormous development of electric lighting we have not made any radical progress in the principal problem of lighting. The goal to strive at should be to produce light without heat. We need cheaper light, not more light. To test the progress made by a new system of lighting, it has been considered all-important to determine the price per candle. Although this value is practically important, it does not give any indication of the real economy, i. e., the ratio of the light produced to the energy consumed. The lighting engineer should base his researches more on scientific principles.—*Zeit. f. Belenoht*, January 10.

Power.

Individual Motor Drive.—Cooper.—An article in which the author points out that in many cases motors are used for driving machine tools which are entirely too small where they are expected to yield a considerable range of speeds by field regulation. Some examples of this kind are mentioned. When installing an electric motor it is important to know the conditions under which the maximum amount of power is required. If the maximum power be coincident with the maximum speed, and the amount of power decreases with the speed, a motor having field regulation is ill adapted to the work of furnishing different speeds. If the power required is nearly constant or if it decreases as the speed increases, this method of regulation is much more applicable. Some remarks are made on the determination of the maximum power required. Due consideration should always be given to the well known facts that the power of a direct-current motor decreases in inverse ratio as the increase of speed when the speed is increased by field regulation, and that the power increases in a direct ratio as the increase of speed when the speed is increased by increasing the volts impressed upon the armature. With field regulation the limiting condition is the tendency to sparking at the commutator, while with regulation by varying the impressed voltage, the limiting condition is heating of the armature. If it is desired to increase the speed 100 per cent. by field weakening, one must have 100 per cent. margin for sparking at normal speed, if the motor is to carry normal load at the increased speed. The same is true in regard to heating, if the speed is to be decreased by lessening the impressed volts. These rules are graphically represented in a diagram. A motor whose speed is to be varied by changes in voltage, field excitation remaining constant, will be directly proportional in size to the change in speed; while a motor whose speed is to be varied by change of field excitation will be in size as the square of the change of speed. For determining relative sizes of motors for constant horse-power application, the following rules are given: The total range of speed, using both variable voltage and field regulation, is as the square of the range of voltages. The change of horse-power is directly proportional to change of voltage on armature, field being constant. The change of horse-power by change of field strength is inversely proportional to change in speed, the voltage on the armature remaining constant. The relative size of motor, as referred to the maximum speed, is directly proportional to its speed variation when using variable voltages. The relative size of motor, as referred to the maximum speed, is as the square of the speed variation when using field regulation.—*Cassier's Mag.*, February.

Electric Power in Australian Railway Workshops.—An illustrated description of the electrical equipment of the railway workshops at Ipswich, Queensland. The power house contains three 200-kw generating sets each consisting of a single-acting compound engine directly connected to a 220-volt, 60-cycle, two-phase alternator. The motors installed vary from 1 to 75 hp and are all induction motors, the majority with squirrel-cage rotors. The number at present installed is about 170 and the aggregate power over 1,200 hp. Where speed regulation is required, the squirrel-cage rotor is replaced by a wound and insulated secondary, connections from which are made by means of collector rings on the shaft to external resistances. Thus the motor is enabled to exert full load torque at a number of speeds less than ful speed, depending on the number of notches in the controller. For crane work, however, suitably designed squirrel-cage motors can be used. The shop equipment includes 11 cranes, each operated by three motors, one for hoisting, one for cross traversing, and one for traveling.—Lond. *Elec.*, January 22.

Power Plant of Apartment House.—Moses.—An article on the general arrangement of the power plant and mechanical equipment of apartment houses. He recommends to get steam from the boilers at 100 to 150 pounds pressure, to use it expansively in the engines, etc., taking a few of the heat units available and allowing the pressure to drop from this initial to 2, 3, 4, 5 pounds as required. Thus, a portion of the energy of the steam is used for producing power, after which it enters the heating system, the drying coils in the laundries and the heater for the water fed to the boilers. In these it loses its latent heat and becomes condensed and returns to a receiving tank, whence it is pumped and returned to the boilers. The following three wiring systems are in use in apartment houses: two-wire 125-volt direct-current, three-wire 125-volt direct-current (one wire having double the carrying capacity of the others so that this is really a two-wire system with one of the wires split in two); a three-wire system with 240 volts between the outers. The first system should be used where no outside service is required; the second where outside service is required for lighting only; and the third where the outside service is required for lighting and power both alternately with the plant. The mechanical equipment is discussed in detail.—*Eng'ing Mag.*, February.

Large Electric Distribution System in Switzerland.—A note stating that the 10,000 water power station near Vallorbe has recently been completed and supplies not less than 190 municipalities with light and power. Current is generated at 13,000 volts and distributed at this voltage.—Lond. *Elec.*, January 29.

French Water Power Plant.—Domar.—A description of the Louziere hydroelectric plant which supplies current to a calcium carbide factory. There are three generating sets, each consisting of a 500-hp turbine coupled with a two-phase alternator.—*L'Eclairage Elec.*, January 23.

Traction.

"Tangential Traction."—Rosenfeld and Zeleney.—Some detailed information on this system which has been noticed briefly before in the Digest, and in its original form described in detail in an article printed several years ago. The principle is that a three-phase winding produces in a stator built up between the rails of the track, a horizontally moving field which corresponds to the rotating field produced by the stator of an ordinary three-phase machine. One

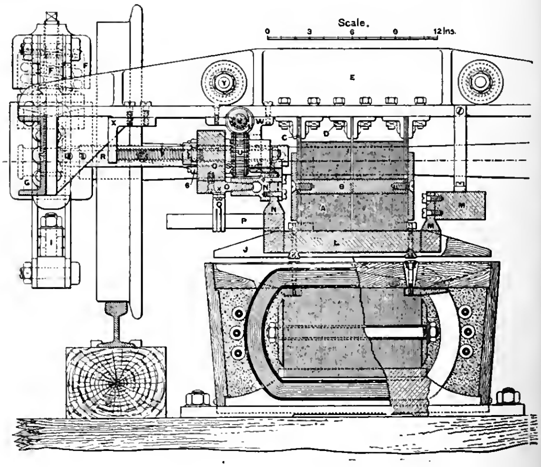

FIG. 5.—"TANGENTIAL" TRACTION.

may consider the stator laid along the track as part of an ordinary stator with an infinite diameter. The magnetic flux, travelling approximately at train speed, cuts the conductors of that part of the system corresponding to a rotor and called "propeller" attached to the motor car. The stator is not laid continuously along the line, but is divided into sections, spaced at certain distances apart. The train receives a constant pull, since the length of the propeller equals the distance between the axis of two stator blocks. Moreover, to avoid energy losses in those stator parts not utilized at the time for propulsion purposes, switching arrangements are provided by means of which only that section of stator blocks is supplied with current over which the train is passing. According to circumstances, a section is composed of one or more stator blocks. In the latter case, each of the three windings of the one block is connected in series with the corresponding windings of the next, and at the distant end of each section the three windings are short-circuited by a switch as the train enters the section. This switch is operated by a small low-voltage three-phase motor, the rails, which are insulated from one another and also in sections, acting as conductors for the rotor circuit. Since the stator of the switch motor is continually fed with current, the rotor will commence to actuate the switch as soon as its circuit is closed by a train entering the section. It is said that by reason of the low voltage in the rotor no special insulation of the rails is required. After the train has passed on to another section the switch opens automatically by means of a counter weight. Fig. 5 shows the section through the propeller and stator block, the right-hand wheel being cut off from the illustration. The stator block is 9 ft. long and 1 ft. 8 in. wide over the pole tips. The pole core has a section of 10 in. by 6¼ in. Altogether there are 24 coils, that is 8 per phase, and they are wound by copper wire 0.1 in. diameter. Current is fed to the winding at a pressure of between 1,300 and 2,000 volts. The propeller has a length of 60 ft., which is about equal to that of the two-bogie cars employed in the tests. The stator blocks were spaced over 18 meters. The propeller is composed of 12 bars, each 5 ft. 1 in. long, which are mechanically, electrically and magnetically connected by means of flexible joints. A squirrel-cage type of winding is adopted for the propeller, which, like the stator, is fitted with laminated pole shoes. For starting, however, the resistance P is inserted in the squirrel-cage winding. A device is fitted to the propeller by means of which the air-gap may be varied, but it seems impossible to make it less than 0.4 in. An experimental line of ¼ mile has been equipped by this system.—From *Bull. Inst. Montefiore, in Lond. Elec.*, January 29.

Vienna.—An illustrated description of the municipal railway system of Vienna which, completed, will consist of about 350 km of track. The bow trolley system is used except in the center, where the underground conduit system is employed. The cars which operate in the center of the city are furnished with two plows, one on each side, with wings which fold up so that they can be lowered into the conduit. The power station is in two parts, one originally built for lighting and the other for railway work, although the two are now operated in conjunction. The coal consumption in October, 1902, was 1.117 kg per kw-hour. The engines in the larger power station are five in number, of 3,400 normal and 4,200 maximum hp, and operate three-phase alternators.—*St. R'y Jour.*, February 6.

Indianapolis & Northwestern Traction System.—An article on this interurban line. The main power plant comprises two steam-driven three-phase generators of 800-kw capacity. Current is delivered at 370 to 400 volts to the rotary converters in the power station, which are used to feed the trolley lines near the station. The remainder of the current is taken by three 300-kw step-up transformers which raise the voltage to 2,600, at which it is transmitted to the sub-stations for distribution. A statistical note states that the mileage of the interurban lines radiating from Indianapolis increased during 1903 nearly 100 per cent., not considering several large projects now under construction.—*St. R'y Jour.*, January 23.

Single-Phase Traction Motor.—See the above description of the Eichberg-Winter motor under Dynamos, Motors, etc.

Installations, Systems and Appliances.

Central Station Statistics of Great Britain.—A supplement to Lond. *Elec.*, January 8, gives a large table of all the electrical central stations in the United Kingdom with no tramway road. Very full information on the equipment is given in about 50 columns. There are in all 264 stations in operation, and 24 in progress of construction. A supplement to Lond. *Elec.*, January 25, contains a table of those central stations which supply current for both lighting and traction. There are in the whole 98 such stations. In an editorial on this subject it is said that when arc lamps of the Bremer and "flame" type made their appearance it was expected that they would revolutionize electric street lighting, but this has not been the case. The number of public arc lamps has remained nearly stationary. It is not expected that arc lamps will be largely employed for side street lighting. Nernst lamps have been extensively adopted, and it is said that for use on continuous current circuit they have established a good reputation, but there is room for considerable improvement in their behavior when worked by alternating currents (the Nernst lamps used in England are from the factory of the Allgem. El. Ges. in Berlin). In different parts of the country the motor connections have increased steadily, in some places even rapidly, the increase being greater for direct-current motors than for single-phase motors. Certain stations have adopted a tariff whereby energy is supplied for motive power at an extremely low rate, provided the consumer will refrain from taking current during "peak hours." Stepney and Brighton are cases in point; in these places a time switch is used, and, outside the prohibited hours, energy is supplied at a flat rate of 2 cents per unit. The number of undertakings "supplied in bulk" from power companies is largely on the increase.—Lond. *Elec.*, January 8.—Diagrams showing variations of the connections to the electricity supply works in London are given in Lond. *Elec.*, January 8; diagrams for the connections in London and in the provinces, in Lond. *Elec.*, January 15. There are also given some summary figures which apply to the aggregate connections to electric central stations, including power and tramway loads, but not including power supplied from purely tramway power houses . The total number of kw now connected in London is 167,640, and in the provinces 488,127, making a total of 655,767 kw in the United Kingdom. This shows an increase of 152,196 kw above the corresponding figure for December, 31, 1902. The equivalent of 8-cp lamps connected in the United Kingdom to date is nearly 22,000,000. The connections to stations under municipal control in both London and the provinces have increased out of all proportion to those under company control, and for the first time the former are now more than double the latter.—Lon. *Elec.*, January 15.

Compensated Potential Regulator for Single-Phase Current.—Fleischmann and Eichberg.—An article illustrated by diagrams, in which the authors first discuss the disadvantages of the ordinary potential regulators for single-phase current, and then describe an improved form which, however, as Osnos remarks, appears to be identical with the induction regulator used by Lamme in his single-phase traction system. (*Elec World*, 1902, Vol. 40, October 4, page 538).—*Zeit. f. Elek.* (Vienna), January 10, 24.

Electric Installations on Board Ship.—Leblond.—The conclusion of his article in which he discusses the general requirements of electric installations on ships. In the present installment he deals with the prime movers to which the dynamos are directly coupled, and with speed regulation.—*L'Ind. Elec.*, January 25.

Electro-Physics and Magnetism.

Radiations Emitted by Righi Vibrator.—Willard and Woodman.—An illustrated description of experiments made to determine the nature of radiation emitted by a Righi vibrator and the dependence of the length of a linear receiver upon the wave length with which it is in resonance, and which was the subject of editorial comment last week. This problem resolved itself into the measurement of the energy received from the same vibrator by resonators of different lengths, and the measurement of the wave lengths obtained with different resonators. The measurement of energy with a linear receiver of definite length showed the existence of a fundamental and upper partials. The relation of the receiver lengths for the fundamental and the successive upper partials stand in the relation 1, 2, 3. The damping in the Righi vibrator is less than the theoretical value computed by Thomson for the radiation from a single sphere. The grating space of the separating surface does not affect the wave length measured.—*Phys. Rev.*, January.

Radioactivity.—Bumstead and Wheeler.—An account of the results of an experimental investigation of the properties of a radioactive gas found in the soil and water near New Haven, Conn. It is apparently identical with the emanation from radium. If any other radioactive constituent is present it can be only in very small proportion. The density of the radium emanating, as determined by its rate of diffusion, is about four times that of carbon dioxide. The authors were unable to obtain the radioactive gas from mercury, recently described by Strutt, and are therefore inclined to attribute his results to an impurity in the mercury used.—*Am. Jour. Sc.*, February.

Magnetic Properties at Low Temperatures.—HONDA AND SHIMIZU.—An account of an experimental investigation of the magnetization and the magnetic variations of the length of ferromagnetic metals and alloys, especially nickel-steel, at the temperature of liquid air.—*Phys. Zeit.*, January 15.

ELECTRO-CHEMISTRY AND BATTERIES.

Electrolytic Rectifier.—COOK.—An account of experiments made to find an explanation of the well-known behavior of the aluminium anode. He finds that the apparent resistance of the aluminium anode in potassium aluminium sulphate is not an ohmic resistance, but a resistance of the transition of the ions, primary or secondary. The formation of a film of alumina which is a very poor electric conductor, prevents the anions from reaching the conducting surface and thus discharging. When the electric pressure is greater than its "critical value" the film becomes crystalline in structure and in crystallizing exposes free metallic surfaces to the action of the anions, allowing them to discharge to the metallic surfaces. The value of the critical pressure and also the counter e.m.f depends upon the temperature. The critical electro-motive force for 1° C. is approximately 47 volts, and for 48° only 22 volts. The counter e.m.f. increases with decrease of temperature.—*Phys. Rev.*, January.

UNITS, MEASUREMENTS AND INSTRUMENTS.

Bending of Magnetometer Bars.—CHREE.—A paper on the source of error due to the bending of magnetometer deflection bars. In magnetometer measurements, the deflecting magnet is carried by the deflection bar at an appreciable height above the centre of gravity of the cross-section, and then bending of the bar when in use, under its own weight and that of the magnet with its carriage, results in an increase of the distance between the deflecting and the deflected magnets. To keep the instrument properly level, there ought to be a counterpoise on the other arm of the deflection bar at the same distance as the deflecting magnet from the centre. In the absence of such a counterpoise, supposing the instrument originally level, the weight of the magnet and carriage causes a slight tilting. In consequence of this the point of suspension of the deflected magnet moves toward the deflecting magnet, thus reducing the horizontal distance between them.—From *Phil. Mag.*, January, abstracted in Lond. *Elec.*, January 22.

Carbon Resistance.—GRAY.—Longden has formerly shown how to make a fairly satisfactory high resistance by depositing soot on a plate of glass whose ends had previously been silvered with a wedge-shaped film. The present author substitutes a tube of glass for the plate. The ends after being silvered are wrapped with a ribbon of stout tin-foil, which is firmly bound on with copper wire so as to make good contact with the silver. Then the soot is deposited between the ends. The resistance tube is mounted on a block of paraffine and for the connections mercury cups are used.—*Phys. Rev.*, January.

Oscillator with Adjustable Capacity.—CASTELLI.—A description of an oscillator in which various systems of electric oscillations can be produced and their wave lengths can be varied continuously within wide limits. The primary and secondary plates consist of sheets of tin-foil suspended by pulleys and counterpoised so that they are at equilibrium at any level. They can also be slid forward or backward so that their distance apart and the amount of surface in direct opposition can be varied at will. In the course of his measurements with this oscillator, the author made an observation which he believes to be new. If a vacuum tube is used for discovering the nodes, and is gradually shifted beyond the node, it remains alight even in places where it would not light up if it approached it from the outside . The author compares this result with the fact that the distance between the carbons in an electric arc can be increased while the arc is playing to lengths at which an arc cannot be ordinarily formed.—From *Nuovo Cimento.*, July, August, abstracted in Lond. *Elec.*, January 22.

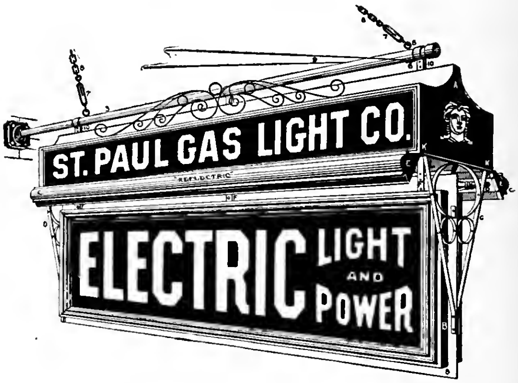
Magnetic Tests of Whole Sheets of Iron.—A fully illustrated description of the method of Richter, used by the Siemens & Halske Company for testing magnetic properties of iron sheets as a whole. The method has been noticed before in the Digest.—Lond. *Eng'ing*, January 29.

Electric Signs.

In giving a real brilliancy to frequented streets at night, the electric sign performs a service to the public, entirely aside from its utilitarian object, though in too many cases appreciation is blunted by inartistic forms and amateur construction, the full effect of which stands out clearly in the daytime. It is only recently that electric sign making has become an art, and before long we may expect to see the amateur sign maker wholly retired from the field. The accompanying illustration of a type of electric sign made by the Western Display Company, of St. Paul, Minn., shows what may be accomplished by inventive skill and making the most of the flexibility of the electric light, together with proper attention as to all mechanical details.

Instead of the ungainly box originating in the day when candles



ELECTRIC SIGN.

were the source of the illumination, the sign proper consists of two enameled plates on either side of a supporting metal frame. This construction, together with the enlarged top portion and the method of mounting produces an artistic effect recalling the pleasing signs of Old Paris. As will be noted, the lamps are mounted in a reflector from which the light is thrown with great brilliancy on the main display panels.

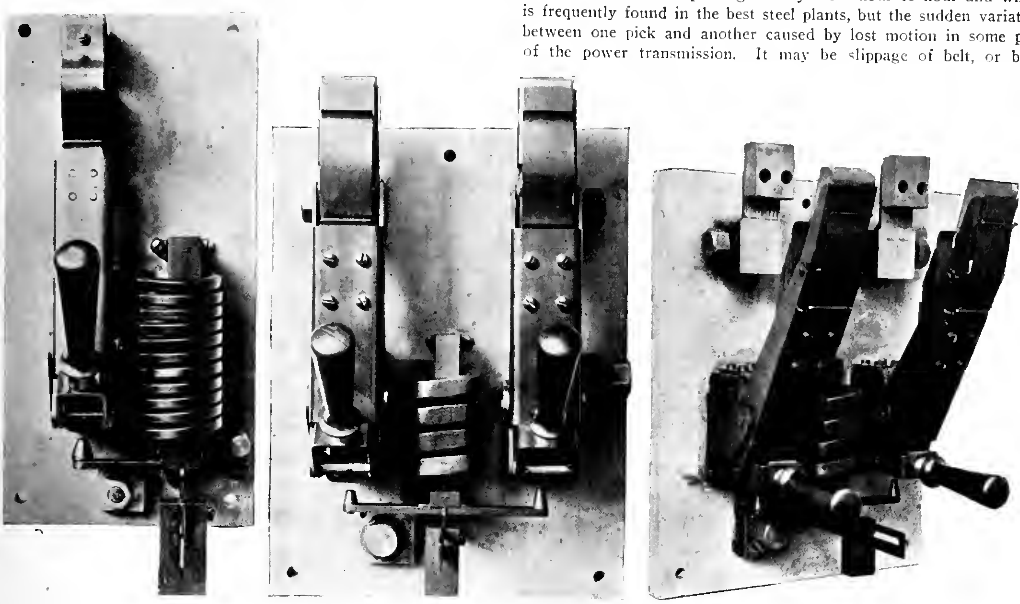
Above the main panels, which are of porcelain, is a glass panel on each side with white frosted transparent letters on a colored background, illuminated by transmitted light. The panels are interchangeable and can be removed without taking down the sign or disconnecting any wires. The wires for the electric lamps are encased in an iron channel and thoroughly protected from the weather. Both the transparent panel and the complete sign are free to swing.

New Type of Carbon Break Circuit-Breaker.

The constantly growing demand for a high-grade automatic circuit-breaker to be sold at a popular price has led to a still further development of existing types by the Westinghouse Electric & Manufacturing Company, resulting in a new type (Type D) which we illustrate herewith. In this device the current is shunted to carbon arcing tips and there ruptured as in the original type of Westinghouse circuit-breaker. The single break is used and the construction is such as to gain the highest degree of efficiency from these and the other features employed.

The circuit-breaker is designed for use upon circuits not exceeding 250 volts, and its distinguishing feature is the simplicity of construction. As will be noted from the illustrations, there is no complicated or hidden mechanism, the entire device being open to inspection. It is small and compact, and thus occupies but little space. There are but few parts, and the most of these are made from punchings, combining strength, lightness and smoothly finished surfaces at a cost which enables the makers to adopt popular prices. There are no springs to get out of order, the only thing of this kind being the flat strip which carries the carbon arcing tip and which also serves to throw back the movable arm when the breaker is opened. All screws are locked and the adjustments are few and permanent.

The movable contact is a laminated brush made from leaf copper and protected by a copper shunt, and so arranged that when the



Figs. 1, 2 and 3.—Carbon-break Circuit-breaker.

breaker is opened the current is shunted to the carbons above. The arc occurs when the final break is made on the carbons, the construction of the contacts aiding the natural tendency of the arc to rise and preventing it from being communicated to the other live parts. Flexible braided leads carry the current from the movable contact brush to the terminal, thus reducing the number of movable current-carrying contacts to a minimum. The temperature rise of the contacts is, in consequence, never over 20° C. with a normal current.

The breaking mechanism is simple. The current passes through a coil through which is thrust one pole of a laminated iron horseshoe electromagnet. The armature is attached to the other pole of the magnet, and is so placed that a current sufficiently strong will draw up the free end of the armature, a movable counterpoise serving to vary the amount of current required. When the armature is drawn up contact points attached to it strike the toggle joints which hold the breaker closed and the circuit is opened. If desired, it can be opened by hand at any time, in the same manner as an ordinary switch.

The circuit-breaker is made with one, two, three or four poles, thus covering all the requirements for alternating-current and direct-current circuits. The single-pole breaker is particularly adapted for use upon motor or lighting circuits when a switch is used in series to complete the circuit after the breaker has been closed. In the two-pole breaker the two poles are closed independently. A switch to complete the circuit is not necessary, as the tripping mechanism is so designed that a short-circuit or an overload will cause the first pole closed to open immediately upon closing the other. This feature combines the functions of two devices at practically the cost of one with added convenience and saving of space.

The three-pole circuit-breaker for use upon three-wire direct current or three-phase alternating-current circuits, and the four-pole circuit-breaker for two-phase alternating-current circuit, are both so arranged that the poles are closed at the same time by the same handle and tripped simultaneously, either by hand or by tripping coils.

As regularly made, the circuit-breaker has front connections, as shown, but when desired for switchboard mounting a threaded copper stud for rear connections is substituted. It is neatly finished in black oxide and presents an attractive appearance.

Motors for a Silk Factory.

Every manufacturer of textiles knows the importance of constant speed in weaving. By this is not meant the slight variation in speed which takes place gradually from hour to hour and which is frequently found in the best steel plants, but the sudden variation between one pick and another caused by lost motion in some part of the power transmission. It may be slippage of belt, or back lash of counters, or many things combined; but the primary cause is that the machine using the power is so far away from its source, thus making its transmission necessary through many belts and counter shafts. In many cases the trouble is so bad that it almost

Fig. 1.—Electrically-operated Silk Loom.

prohibits the making of light weight goods. Many things are tried to overcome the trouble, and journals are tightened up until the loom will barely run, or speed is reduced, or more picks are put in. Any one of the three may partly correct the evil, but any one of them only adds to the cost of production. This is one reason why looms, especially those utilized in the manufacture of silk, both in broad goods and ribbon, are not driven at their maximum speed. Silk calls for the most extreme regularity of texture. Whatever the quality of the goods, the beauty of the finished piece depends greatly on its evenness. To get this regularity, speed and production are sacrificed, because there is a limit at which a belt-driven loom can be run and make even work. If the limit is exceeded the momentum of the backward and forward motion of the lay is increased. The fly-wheel loses the control it has at a slow speed, and the blow of the lay becomes uneven, because the accelerated motion of the loom has also increased many fold whatever lost motion was in it before and "shirry" cloth is the result. In order to keep up the speed the plan is to put in more picks and so offer a better resisting medium to the blow of the lay, thus overcoming in a measure the defects. But this is wasteful. If we have a loom belted to the main shaft a higher speed can be obtained and better goods can be turned out than when the power is taken through many counter belts and shafts. All looms cannot be belted to main shafts, or, in other words, the power cannot be taken direct from its source, that is, from the engine to the loom. It cannot be done by belts, but it can be done by means of individual motors which seems especially adapted to the weaving of silks from the lightest to the heaviest fabrics. It might be thought too delicate a piece of mechanism to do the work; that the sudden jar caused by the banging off of the loom might wreck the motor; but it stands the strain under the severest tests even when geared up without the interposition of huffer springs.

As to gearing a motor direct to a loom: Some advocates of a belt connection between motor and loom say that it is necessary to act in a manner as an absorbent of the momentum, so that when the loom stops suddenly the elasticity of the belt and the slippage of the pulley inside it will prevent any jar to the motor. Others who favor belt connection are the makers of motors, who wish to connect the motor up without trouble. It is claimed that is one reason why so many failures have been made in electrically driven looms. Instead of an electrician looking into the matter and adapting his motor to textile requirements, he insists on putting in a motor which, however well adapted it may be to run a fan, sewing machine or lathe, is not suitable to put on a loom. The mechanical electrical requirements of a motor for a broad silk loom are many. First it must be made to gear into the loom by means of a steel pinion. Then the motor must stop when the loom is stopped. The motor stops the loom in the same way that the motor starts it—by throwing the current on or off—with no secondary motion by throwing out or in a clutch and then the current. Another thing necessary is that the motor starts at full speed instantly, for where a loom holds a flying shuttle, it is absolutely necessary to start at full speed in order to drive the shuttle across and into the box with just the right force and it will not do to have it start too quickly and consequently give too much force to the blow of the picking stick.

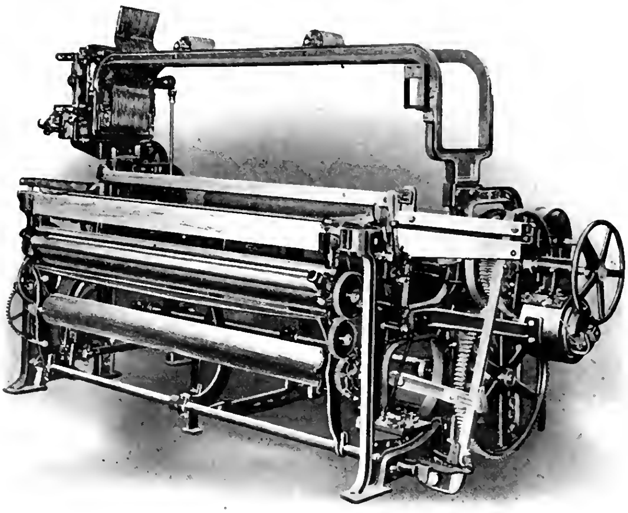


FIG. 2.—ELECTRICALLY-OPERATED SILK LOOM.

It is a great advantage also to have three speeds to a motor—the normal speed at which the loom is built to run, and say 12½ per cent. over and under. The motor should be light enough not to be cumbersome and yet strong. It should be directly attached to the loom and not to the floor. It should have plenty of reserve force behind it, so as to prevent it from unduly heating up when running, and that it may run equally well at a high or low speed. The higher the speed of course the more poweer is required from the motor and it also requires a reserve power in order to adapt it to the different fabrics woven in the same loom. At one time it may be a light taffeta requiring but very little power, while at other times a heavy brocade is being handled which would task the motor much more.

The silk factory at Andover, N. Y., owned by the Rochambeau Silk Company, has recently been installed throughout with motors directly connected to the looms, warpers and winders. This is the only silk plant in the country that is completely operated by direct-connected motors. The Northern Engineering Company secured the contract. There are 60 motors in all. They are ½-hp standard loom motors built by Roth Brothers & Co., of Chicago, Ill., and direct connected to Crompton-Knowles looms. The generating plant consists of a 50-hp Nash gas engine, vertical self-contained three-cylinder enclosed type, direct-connected to a 30-kw, 110-volt, 250-r.p.m. generator, built by the Commercial Electric Company of Indianapolis, Ind.

Nernst Lamp Company's Training School.

The Nernst Lamp Company will henceforth adopt the policy of establishing district offices in the larger cities of the United States and will deal directly with its trade through these branch offices, thereby resulting in a closer relationship between the manufacturer and the user. Each district office will carry a complete stock of the company's product and be in a position to give prompt attention to all orders received from its territory.

In carrying out these plans, the company finds it necessary to increase its selling force and will soon add to its staff a number of additional salesmen.

To increase the efficiency of its representative and other employees of the sales department, the Nernst Lamp Company have organized an "apprenticeship course" embracing a period of six weeks' time, during which time the apprentice will receive a nominal salary amply sufficient to pay all necessary personal expenses. The first two weeks will constitute a probationary period and will be spent in the nearest office of the company to which application is made, under the supervision of the district manager. While here the apprentice will have the opportunity of noting the methods employed by his tutor and assisting the latter in the discharge of his field and office duties. The remainder of the course will be given in the company's factory at Pittsburg, the third and fourth weeks being devoted to a detailed study of the mechanical and electrical features of the Nernst lamp, and the proper conditions and methods involved in its installation. This portion of the course will be concluded with a written examination on the work thus far encompassed. The fifth and sixth weeks will be spent in the study of maintenance and sales department systems and in practical work, in the maintenance and repairing of lamps, in the preparation of lighting plans, estimates, etc., and in actual soliciting under the tutelage of an experienced salesman.

Having completed the regular course to the satisfaction of his employers, the apprentice will be given a certificate to that effect and sent either to one of the branch offices where he will at once assume the duties of salesman or maintenance man under the supervision of the district sales manager, or to the Nernst lamp department of one of the company's central station customers. It is expected that the central station trade will constitute the bulk of the future business of the Nernst Lamp Company.

NEWS OF THE WEEK.

Financial Intelligence.

THE WEEK IN WALL STREET.—The stock market was unfavorably affected by the hostilities in the East, the Baltimore fire and fears of extensive liquidation of securities by insurance companies. There was little public interest of a sepculative character and professional operators were bearish. One of the features of the market was the sustained strength shown by the United States Steel issues, which tended to advance in the face of the early weakness and held fairly well during the later depression, seeming to be the objects of a certain amount of short covering and of fresh accumulation. A good deal was heard regarding the probability that large contracts would be placed for the steel structural material required by Baltimore, and it was also claimed that the corporation will display large export sales this month, and that a readjustment of steel rail prices will be satisfactorily arranged with the railroads. There was some manipulative activity in Brooklyn Rapid Transit and other issues, but they did not attract any general attention. The curb market was heavy throughout the week with evident efforts by insiders of various corporations to realize on their holdings. Greene Copper sagged in connection with the new stock issue so that the rights became of slight value. The market for electric and traction stocks was in the main weak, closing at lower prices. American Telephone and Telegraph ruled at 123, closing at that figure, which was a net loss of 3 points. Western Union lost ⅝ point, closing at 87⅛. Brooklyn Rapid Transit was the exception and made a net gain of 2⅜ points, closing at 42¾ after having reached 43½. Metropolitan Street Railway fluctuated between 115 and 118, closing at 117½. General Electric lost 4 points on the week's business, closing at 166, after having reached 169. The closing figure was but one point above the lowest of the week. Westinghouse common closed at 160¼. Following are the closing quotations of February 16:

EVERETT-MOORE TELEPHONE.—The creditors' claims against the Everett-Moore Telephone properties represented in the companies controlled by the Federal Telephone Company amount to about $3,500,000. Recently these creditors agreed to an eighteen months' extension of credit. It is stated that in the meantime these obligations are being funded, creditors being asked to take collateral trust bonds of the telephone properties. It is thought that this collateral will be marketable at the expiration of the period at a figure that will cancel all obligations. The bankers' committee still has charge of all Everett-Moore affairs, which are in the hands of an executive sub-committee. It seems improbable that the bankers' committee will be relieved short of the time stated. The Everett-Moore security holdings are all held by the bankers' committee, or rather subject to their order, as nearly all of it is hypothecated for loans in local banks. In the present state of the security market, the holdings would liquidate at a price that would leave the syndicate bankrupt, probably to the amount of the telephone indebtedness. Under favorable monetary conditions the syndicate could probably wind up within a year and come out a little ahead, but the bankers' syndicate has done so well that there is little likelihood of sacrificing values in order to make a clean-up. The expectation is that within a reasonable time all obligations will be so funded on the basis of marketable securities, so that in time the syndicate holdings will be released largely intact and representative of a handsome equity.

NEW YORK INTERBOROUGH.—The Interborough Rapid Transit statement covering operations of the Manhattan elevated lines for the quarter ending December 31, shows the best results in Manhattan's history. As compared with the corresponding period in 1902, the following increases are shown: Gross earnings increased 13.9 per cent.; net earnings increased 21.8 per cent., and surplus after charges increased 65.5 per cent. The item of charges which includes, besides interest and taxes, the dividend on Manhattan stock appears to have been swelled to some extent by the inclusion of certain sums in connection with the adjustment of some tax claims, but for the settlement of which the final surplus might have been somewhat larger. It is understood that the statement presented might have been made to look much more favorable were it not considered good policy to foster a very conservative view as to the real earning capacity of the property. A less "conservative" statement might have the effect of renewing the labor agitation which broke out among the company's employes more than once last year. The gross for the quarter was $3,657,709 and the the net was $2,261,314. The gross for the nine months was $9,868,249 and the net was $5,862,144.

COMMERCIAL CABLE STOCK.—Note is made of the recent advance in Commercial Cable. Business has been good, and the war makes it better by the demand for news. The Postal Company, owned by the Commercial, has just completed 550 miles of line between Omaha and Denver, giving it a third route a large portion of the way across the continent to handle the increase in business caused by the extension of the cable from Honolulu to Manila, which affords connection with China, Japan and the Far East. Upon the completion of this cable July 4 last, the rate from China and Japan was reduced from $2 to $1.12 per word from New York, and the press rate from $1 to 50c. per word. As a result of war this cable service will be employed largely by the press of the United States and Great Britain, as better time can be made this way across America for England, than by the Suez Canal.

BELL TELEPHONE REQUIREMENTS.—A leading Boston interest in the American Telephone and Telegraph Company says: "The American Telephone and Telegraph Company will this year need $20,000,000, but it may not need this money until the fall, although the company generally raises its money in July. It may be that the company will this year issue convertible 5 per cent. bonds, although the president recently informed me that this subject had never been given consideration. It may be considered better policy for the American Company to become a borrower of money this year than issue new securities if market conditions are not better next summer, than at present. The American Telephone and Telegraph Company may use a portion of a new capital issue this year for the acquirements of certain independent companies which it can secure at an equitable price." The statement comes from Boston that it is the intention of the American Telephone and Telegraph Company directors to issue some time within the next four or five months $15,000,000 in bonds. President Fish is now in California and is expected to return about April 1. After that the matter will probably be taken up for consideration. Nothing has been determined upon as to the rate of interest the bonds will carry. That matter will be decided probably by the money market. Some talk has been heard regarding convertible bonds, but nothing beyond the fact that $15,000,000 will be needed has as yet been determined upon.

WISCONSIN CONSOLIDATION.—The Construction Company of North America, of New York, has secured control of one of the most important interurban railways in Wisconsin. The company has been building the interurban line from Sheboygan to Plymouth, and the new power house of the Sheboygan Light, Power, and Railway Company, and with the securing of control will come the transfer to the New Yorkers of the local electric system as well. The properties are worth about $1,000,000, but the importance of the deal is in the fact that this road will be the vital link in the proposed line from Fond du Lac to Kaukauna, forty-five miles in length.

CAPITAL TRACTION CO., of Washington, D. C., reports gross of $1,413,312 for 1903, and net $822,374; charges and taxes, $114,187, dividends, $600,000. After various provisions for construction, equipment, etc., the surplus December 31 was $31,678.

DIVIDEND.—The Kings County Electric Light, Heat and Power Company has declared the regular quarterly dividend of 2 per cent.

Commercial Intelligence.

THE WEEK IN TRADE.—A summary of trade reports from the various sections of the country shows that temporary irregularities exist, due largely to the continued cold weather. The Baltimore fire and the war in the East have also affected trade more or less. In the West the cold weather checks spring trade expansion, but in the leading Eastern markets there is some activity. In the South distribution continues active. The great fire in Baltimore and the hostilities between Russia and Japan have affected the speculative markets to some extent, and the strength of prices in many commodities is attributed to the latter development. Conservatism in industrial operations is the rule. Money is easy and the banking situation is a very strong one as regards supplies of liquid capital, but currency has ceased to flow from the country, and with enlargement of activities in all lines a firmer market is looked for. Railway operations are showing decreased gross earnings, due to the severe weather of January, following reduced net earnings in December. Building operations in Baltimore will naturally develop a large inquiry for structural and building material. Country buyers are increasing in number at Chicago, St. Louis and Kansas City, and reports from these centers indicate that a good spring trade is anticipated. In the Northwest dullness prevails owing to the cold weather, but a fair business is being booked. In the Duluth district, lumber mill operations are active. Trade is improving on the Pacific Coast, with special activity in war supplies. The iron trade is irregular, but the railroads have begun to buy. Other metals are dull. Copper was further reduced in price, and the market was very weak. The official quotations of the Metal Exchange were marked down another ⅛c., the closing figures being 12¼ to 12½c. for Lake; 12⅛ to 12⅜c. for electrolytic, and 12 to 12¼c. for casting stock. The London market is also down. *Bradstreet's* reports 202 business failures for the five days ending Feb. 22, against 216 the week previous and 217 the corresponding week last year.

NEW TELEPHONE SYSTEM FOR MEXICO CITY.—The construction of an extensive up-to-date Yankee telephone system is contemplated in Mexico City. S. G. McMeen, a Chicago telephone expert, is now in the capital of the Southern republic making a study of the field and mapping the results as a final preliminary to the digging of the trenches and the laying of the conduit and cable. The cables in the underground section of the city will be laid in terra cotta conduit at a depth of about three feet from the surface. At distances of every 500 feet, manholes will be placed so as to facilitate repairs to the cables. The weight of the cables will be about six pounds per running foot. A new central station will be constructed. The visual signal system will be employed. Plans and specifications are now in process of being drawn up, and it is expected that contracts will be awarded within the next few weeks.

THE INTERNATIONAL TELEPHONE MFG. CO. of Chicago recently closed a contract with the Kansas Telephone and Electric Company of Parsons, Kan., for a complete new central office equipment consisting of a 1,000-capacity, 600-equipped, mechanical self-restoring dropboard and protective devices, also 200 International telephones. The board is the International Company's latest design and is equipped with flash light transfers, pilot lamps in connection with both the line and clearing-out signals, and is thoroughly up-to-date in every respect. The International Company states that during the past 90 days it has secured orders for switchboards aggregating over 6,000 drops equipped, and has recently found it necessary to increase its capacity to take care of the growing demand for its product.

JANUARY FOREIGN TRADE.—The statement of international trade for January showed a large balance in favor of the United States. This was expected in view of the high prices for cotton and breadstuffs in connection with the tendency for imports to decrease. The balance of trade in favor of the United States in January was $59,044,000, being $10,226,000 in excess of January, 1903, and $9,038,000 in excess of 1902. The imports of merchandise in January decreased $2,505,000 as compared with January, 1903. For the seven months ended January 31 the balance of trade in our favor amounts to $363,399,000, being $104,932,225 over the same period in 1903, and $16,747,000 over the corresponding period in 1902.

ACQUIRES SULZER PUMP PATENTS.—The International Steam Pump Company recently acquired the rights to manufacture the high-lift centrifugal pumps constructed by Sulzer Brothers, of Winterthur, Switzerland. After considerable experimental work, the company has produced a pump which is claimed to be so far an improvement over the ordinary centrifugal pump that heads up to 2,000 feet may be overcome with high efficiency. These pumps will be manufactured on an extensive scale at the new Worthington Works at Harrison, N. J. Numerous contracts have already been secured for equipments to be operated by motors.

ELECTRIC TRACTION FOR VERA CRUZ.—The construction of an extensive electric traction system in Vera Cruz, Mexico, is projected. The present horse tramways in that part of the world are about 11 miles long. They are controlled by the British contracting firm of S. Pearson & Son, who have large harbor and railroad construction contracts in hand in various parts of the republic. Sir Weetman D. Pearson is president of the Vera Cruz Company. In addition to converting the existing lines to electric motive power, it is proposed to extend the system considerably.

BLOCK SIGNALS FOR MISSOURI PACIFIC.—The Missouri Pacific Railroad has contracted with the Union Switch and Signal Company for the installation of an electrical automatic block system on all its main line tracks. Work will be begun at once on the 283 miles between Kansas City and St. Louis. Signals will also be put in on the first 165 miles of track on the Iron Mountain Road out of St. Louis, and on the line between St. Louis and Poplar Bluff by May 1. The system will then be gradually extended to the other lines of the Missouri Pacific.

EQUIPMENT FOR RAILROAD SHOPS.—The firm of Mackenzie, Quarrier & Ferguson, Engineering Building, New York, has secured a contract from the Australian General Electric Company—which is the Antipodean branch of the General Electric Company—for a 150-hp Harrisburg standard simple engine; also an 80-hp one. Both engines are to be belted to General Electric generators of 85-kw and 50-kw capacity each. The equipment, it is understood, will be installed in New South Wales government railroad shops.

NILES CRANES FOR BALDT STEEL PLANT.—The Baldt Steel Company, which is constructing a large plant at Newcastle, Del., to be equipped with considerable electrical machinery, has awarded a contract to the Niles-Bement-Pond Company, 136 Liberty Street, New York, for the electric overhead traveling cranes to be installed. There will be five equipments, varying in capacity from 10 tons to 30 tons. Jeremiah J. Kennedy, 52 Broadway, New York, is acting as consulting engineer to the Baldt Company.

ALBERGER CONDENSER FOR WESTERN PLANTS.—The Alberger Condenser Company, White Building, New York, has just taken two substantial Western contracts for its specialties. The Economy Light and Power Company, of Joliet, Ill., have ordered a high-vacuum condensing equipment. A similar equipment, also a cooling tower, is to be installed in the plant of the United Gas and Electric Company, of New Albany, Ind.

LIGHTING A PASSENGER STEAMER.—The large passenger steamer, the "City of Buffalo," is now being lengthened at the Detroit Ship Building Co., Detroit, Mich., and an increase in the electric light plant is being made by the addition of a 90-hp direct-connected unit. The Western Electric Co., Chicago, will furnish the generator, and the Ball Engine Co., Erie, Pa., the engine.

SALE OF SECOND-HAND ENGINES.—The engines of the Eightieth Street power station of the New York Edison Company have been sold to the Whitehead Machinery Company of Davenport, Ia. The equipment consists of two 300-hp simple condensing and four 900-hp tandem compound condensing Hamilton Corliss engines.

EDISON'S STORAGE BATTERY IN ENGLAND.—Thomas A. Edison's new storage battery is to be placed on the British market. A strong syndicate, headed by Sir Ernest Cassel, and in which H. F. Parshall, the well-known American electrical expert, is interested, will float a company for the purpose of acquiring the British rights.

LEFFEL WHEELS FOR 3,000-HP PLOW-MAKING PLANT.—The Oliver Chilled Plow Company is to install a large electrical equipment for the purpose of operating its plant at South Bend, Ind. About 3,000 hp will be developed by means of water. James Leffel & Co. secured the contract for the wheels.

EQUIPMENT FOR MEXICAN PAINT FACTORY.—Extensive paint and color works located at Irapuato, Mexico, are to be entirely operated by electricity. Steam power is employed at present. Ricardo A. Barkley is the proprietor of the works.

EQUIPMENT FOR MEXICAN FLOUR MILLS.—Large flour mills located at Irapuato, and owned by F. J. Randall, of that Mexican city, are to be electrically operated throughout, and contracts will be awarded for the necessary equipment.

PLUMBAGO IMPORTATIONS.—Figures from McCullough-Dalzell Crucible Company show importations into the United States from Ceylon in 1903, of 44,013 barrels of plumbago in lump, chip, dust, etc.

General News.

THE TELEPHONE.

CONWAY, ARK.—The Conway Telephone Company has been chartered, with a capital stock of $10,000. L. H. Pyle is president; F. E. Perminter, vice-president, and Gussie E. Pyle, secretary and treasurer.

LOS ANGELES, CAL.—The Home Telephone Company is considering the advisability of advancing its commercial rate from $4 to $5 a month.

SAN DIEGO, CAL.—The Home Telephone Company has paid $300 for a franchise to operate in this city. A plant costing at least $120,000 is promised. Long distance communication with outside cities has been arranged through the United States Telegraph & Telephone Company.

LOS ANGELES, CAL.—The stockholders of the Pomona Valley Mutual Telegraph & Telephone Company have voted a $20,000 bond issue, bearing 6 per cent. interest. The money thus raised is being used for construction purposes. The company has contracts for 500 telephones, 400 of which have been installed.

HARRISON, IDA.—The Interstate Telephone Company is installing many telephones here, in active competition with the Bell Company.

HARRISONVILLE, ILL.—The Harrisonville Telephone Company has increased its capital from $20,000 to $30,000.

KNIGHTSTOWN, IND.—About 125 representatives of independent telephone systems met at New Castle and perfected a permanent organization by electing O. H. Garriott, of Cadiz, president.

INDIANAPOLIS, IND.—The Cynthianne Telephone Company has filed articles of incorporation. The capital stock is $3000. John T. Arnett, U. C. Canada and Floyd Whitsel are the incorporators. The principal office will be in Cynthianne.

VELPEN, IND.—The Velpen Home Telephone Company has filed articles of incorporation with the Secretary of State. The capital stock is $5000. The company will build and operate in Pike and Dubois counties with principal exchange and office in Velpen. L. R. Bradwell, W. S. Risley, A. S. Morgan and others are the incorporators.

SHELBYVILLE, IND.—The Mutual Telephone Company is establishing a rural exchange in Sugar Creek Township, another in Van Buren township and a third system in the neighborhood of London and Boggstown. In addition to connecting up these rural lines the company expects to erect a line west on the Marietta pike connecting a number of residences.

CUMBERLAND, IND.—The Cumberland Telephone Company, of this city, is preparing to make important and extensive improvements. The concern was organized over a year ago, with a capitalization of $10,000. The officers are: William Gale, president; F. W. Weise, secretary. A new exchange will be built in Cumberland, and considerable money will be expended in extending the lines to supply the large demand for service.

NEW CASTLE, IND.—The officials of the 14 independent telephone companies in Henry County held a meeting on February 1, and effected an organization for the purpose of co-operation, the exchange of service, mutual benefit, to encourage the extension of lines and to unite in an effort to fight competition introduced by the Central Union people. Dr. Garrett, of Cadiz, was made president, and George Watts, of Knightstown, secretary.

WABASH, IND.—The Central Union Telephone Company, which has been operating here without a franchise for the past four months, has made formal application for a franchise. The council directed the city clerk to notify the company that unless the officials sign and accept the franchise offered to the company some time ago, the city authorities would begin the removal of all poles and wires in the streets and alleys. It is generally believed that the company will accept the franchise as it stands.

SHELBYVILLE, IND.—The Central Union Telephone Company has perfected plans for the rebuilding of all its outside construction and installing a new switchboard. The new switchboard equipment will be of the central energy type of the Western Electric Company. It is the purpose of the management to extend the use of the telephone to every town, no matter how small, throughout the entire Shelby County, and at all places to put telephones in at the most reasonable rates consistent with good service.

RICHMOND, IND.—The annual meeting of the Richmond Home Telephone Company was held February 2, and the following persons elected directors: E. H. Cates, Samuel Dickenson, J. W. Moore, J. M. Lontz, A. C. Lindemuth, L. M. Flesh and W. P. Orr. The present officers were re-elected, including A. C. Lindemuth as president. The company has enjoyed a remarkably prosperous year. Four hundred and nine new telephones were installed during the year, making the total present number 1971. It is expected that the 2000 mark will be reached soon.

AUGUSTA, ME.—The Plymouth Telephone Company has been organized at Plymouth, with a capital stock of $10,000. The officers are: President, A. O. Ward, of Plymouth; treasurer, W. G. Loud, of Plymouth.

WAVERLY, MINN.—The Wright County Telephone Company has been incorporated with a capital stock of $50,000. The directors are G. W. Jennings, C. E. Wright and others.

MEXICO, MO.—A meeting of telephone managers will be held to devise a plan to have all of the lines in Audrain County meet at a central point, probably in this city. J. N. Rosser, of Rush Hill, president of a company forming for the construction of a line from this city to Laddonia, is the promoter of the project.

MIDDLETOWN, N. Y.—The new officers of the Orange & Sussex Independent Telephone Company recently elected are as follows: President, George G. Otis, of Newburgh; vice-president, George F. Ketcham, of Warwick; secretary, M. C. Tuthill, of Washingtonville; treasurer, W. D. Haggerty, of Sussex.

OSWEGO, N. Y.—The City Council has granted a franchise to the Empire State Telephone & Telegraph Company to construct a subway for its wires and cables in West Bridge Street and West Second Street of this city.

LIBERTY CENTER, OHIO.—The Farmers' Mutual Telephone Company has been organized, with A. C. Clinton, president. The company will build a farmers' system.

CRESTLINE, OHIO.—The Bell Telephone Company is making an effort to secure a new franchise in Crestline. Some years ago it secured a franchise, but did not build.

NORWOOD, OHIO.—The Norwood Citizens' Telephone Company has applied for a franchise and will probably secure the grant. At present the Bell Company holds the field.

WESTON, OHIO.—The Weston Telephone Company has elected S. A. Murphy, president: G. B. Spencer, treasurer. The company reports a good gain during the past year.

URBANA, OHIO.—The United States Telephone Company has completed a line between Urbana and Springfield, and the Urbana Telephone Company is now giving long distance connection with all points south of the city.

MT. PLEASANT, OHIO.—The Mt. Pleasant Telephone Company, capital stock $5000, has been incorporated by J. M. Bennett, J. A. McGlenn, Michael Gallagher, C. P. McMillan and E. B. Jones. An exchange will be built at Mt. Pleasant.

PAINESVILLE, OHIO.—The Painesville Telephone Company has elected F. A. Searl, president; W. R. Radcliff, treasurer, and C. M. Grauel, secretary and manager. The company made a good gain during the year, and has recently installed a new switchboard.

HAMILTON, OHIO.—The Hamilton Home Telephone Company has elected Frank Hart, president; J. W. Shoneher, secretary; F. W. Whitaker, treasurer, and A. B. Crawford, general manager. The company has about 1500 telephones in operation and is making rapid gains.

BRYAN, OHIO.—O. L. Spanger has been appointed general manager of the Bryan Consolidated Telephone Company, which has recently absorbed the Williams County Toll Line Company and the Bryan Telephone Company. The company is planning numerous extensions this year.

CANTON, OHIO.—The Stark County Telephone Company has elected F. S. Dickson, president; R. W. Judd, treasurer, and A. S. Hillhouse, secretary and general manager. The company is planning to extend its lines throughout the county, and will install several exchanges in small towns.

CONNEAUT, OHIO.—E. S. Barber and J. S. Brailey, of Wauseon, who built the Conneaut Telephone Company's system, have retired from the management of that company, and J. G. Palmer has been appointed manager. The company now has 676 telephones, an increase of 24 during the year. It will make improvements this year.

BELLEVUE, OHIO.—The Local Telephone Company has elected C. R. Callaghan, president and general manager; Frank Knapp, secretary, and J. H. Beatty, treasurer. The company owns exchanges in Bellevue, Norwalk, Chicago Junction, Berlin Heights, Greenwich, Monroeville, Plymouth, Milan, New London and Attica, and has over 200 miles of toll lines. It has 2300 telephones in service, and with improvements planned for it is expected the number will soon reach 3000.

CINCINNATI, OHIO.—The City Council has refused the various applications for independent franchises in the city, and all the applicants have applied to the probate court under the law which provides that companies may appeal to the probate court in case the application has been refused by the Council. The four competing independent companies are the Queen City Telephone Company, the Fitzsimmons Telephone Company, the Interstate Telephone Company and the Cincinnati Telephone Company.

COLUMBUS, OHIO.—Several bills of interest to telephone people have been introduced in the Ohio Legislature. Representative Ely, of Ashland County, has a bill to compel rival telephone companies to make concessions so that subscribers on one line may talk to subscribers on the other line on payment of a fixed toll. The bill provides that the connection must be made by the company desiring the connection. Representative Judy, of Darke County, has a bill limiting telephone rentals in all cities to $6 per month for business telephones and $3 per month for residences. This applies to old as well as new companies.

SCRANTON, PA.—The Pennsylvania Telephone Company is improving its service in this city and will expend $200,000 in the work. The improvements will include the installation of a new switchboard.

HUNTINGTON, W. VA.—The Bell interests have obtained control of the Ohio Valley Telephone Company, which has lines extending from Huntington to Pomeroy, Ohio.

BARABOO, WIS.—The Baraboo Telephone Company has amended its articles of incorporation in order to increase its capital stock from $30,000 to $50,000.

LARAMIE, WYO.—The Rambler Telephone Company will build a line from this city a distance of 18 miles to Tie Siding, where the line will be connected with an extension of a telephone line from Fort Collins, thus giving communication with northern Colorado towns.

OTTAWA, ONT.—Mr. Frank J. Leonard, general manager of the Canadian Telephone and Telegraph Company has written to the city clerk of Toronto, Ont., that his company is ready to do business with the city on the following basis: "Business telephones at a yearly rental of $36, residences at $24. We will pay to the city for competitive franchise the same fee that the Bell Telephone Company has been paying for exclusive privileges. We will build a conduit system through the principal streets of Toronto, as may be required by city ordinance, or, in case the city would build its own conduit system, we agree to lease ducts in said system, sufficient for our business at such rental as may hereafter be decided upon."

Electric Light and Power.

SAN FRANCISCO, CAL.—The California Gas & Electric Corporation, which maintains 820 miles of high-potential transmission lines and branches, exclusive of distributing systems in cities, lost only three insulators during the first 37 days of 1904. Locke insulators are used largely, and 40,000 volts is carried.

SAN FRANCISCO, CAL.—The Northern California Power Company will soon erect a three-story brick and stone building in Redding, Cal., for a general headquarters for the company, which operates about 100 miles of electric transmission lines. Supplies will be carried, and an electric repair shop will be located in the basement.

SANTA ROSA, CAL.—A committee of the City Council of Santa Rosa has received a report from Thomas Merk, of the Engineering Offices. He estimates that it would cost $30,000 to install a municipal plant to generate current for 100 arc lights, using steam from the city water works station. His figure on a plant to supply 6000 incandescent lights was $50,000.

SAN FRANCISCO, CAL.—The Mutual Electric Light & Power Company, of San Francisco, has filed the following report of its business for the year 1903: The total receipts were $115,051.94, including $114,788.20 from light and power. The expenditures were: General expenses, $25,975.23; manufacturing, $58,106.12; distribution $11,202.12; total, $95,283.47. The original cost of the plant is placed at $519,993, but its present value is said to be unknown. The capitalization is $500,000, and 41,000 of the 50,000 shares have been issued. A $400,000 bond issue has been authorized, but the bonds have not yet been sold. The floating debt outside of that portion covered by cash on hand, outstanding accounts and collectible assessments, amounts to $58,447.99. Two 1500-kw three-phase generators, with engines which are to be direct connected, are on the ground and will be installed as soon as arrangements are completed for commencing the new power station.

SAN FRANCISCO, CAL.—The American River Electric Company, of which Mortimer Fleishhacker, of San Francisco, is president, is now supplying the city of Stockton, Cal., with current from its water power electric transmission system. Commercial light and power circuits are included. The first 1500-kw Westinghouse 3-phase generator has been in operation or several weeks, lighting Placerville and operating a 250-hp gold dredge at Jenny Lind. The plant is on the American River near Placerville. A second 1500-kw generating unit is ready for operation, and it is the intention of the company to order a third unit which will probably be installed before the end of this year. The Folsom Development Company's large gold dredge at Folsom, Cal., is now receiving power from the American River Electric Company. The first dredge was recently completed, a second is in course of construction and a third will be commenced soon. It is estimated that ten gold dredges will be in operation in the vicinity of Folsom within a year. The American River Company established a record for rapid electric construction work on the Coast in building this plant and about 100 miles of pole line between May, 1903, and January, 1904.

WASHINGTON, D. C.—The National Light, Heat and Power Company has been incorporated by P. H. Kennedy, H. E. Warren and C. D. Wright; capital, $500,000.

WASHINGTON, D. C.—The Pan-American Electric Light & Power Company has been incorporated with a capital stock of $1,000,000. The incorporators are: Morris Simon, Max R. Raubitschek, William I. Murphy, R. S. Donaldson, E. W. McCormick, S. A. Terry and others.

JEFFERSON, GA.—Judge H. W. Beal and Paul B. Matthews are considering the advisability of establishing an electric light plant and water works.

CHICAGO, ILL.—The Commonwealth Electric Company is stated to have purchased property adjoining its present works; the plant will be enlarged.

CICERO, IND.—The Town Board has taken steps toward the building and installation of an electric light plant.

TIPTON, IND.—It is reported that the municipal electric light plant is to be enlarged.

EAST CHICAGO, IND.—The Indiana Trust Company, receiver, has recommended that the equipment of the East Chicago electric light plant be improved.

FT. WAYNE, IND.—The City Council has adopted the report of the committee on contracts and franchises, recommending the passage of the ordinance granting the Jenney Light and Power Company a franchise.

AURORA, IND.—The City Council has notified the Aurora Gas & Electric Light Company to discontinue lighting the city after March 1, and to remove its poles and wires from the streets within 20 days after the expiration of the contract, March 1.

INDIANAPOLIS, IND.—The Indianapolis Board of Public Works will advertise for bids until February 25, for a 10-year contract for electric lighting of the city. The specifications call for 1600 arc lights of 2000 cp each and 500 incandescents of 50 cp each. G. E. Fisher, representing the Fidelity Construction Company, of Detroit, has surprised the board with a proposition to build a modern municipal lighting plant, to operate it for 10 years, and then sell it to the city at a merely nominal price.

MUSCOGEE, I. T.—The Muscogee light and power plant, ice plant and gas franchise have been sold to a Chicago syndicate. This plant was built and owned by C. W. Turner and was the first electric light plant built in Indian Territory. With the plant goes a gas franchise granted by the city to the company, and an agreement and bond to construct and operate it. The consideration was $125,000. The Chicago company will also build a street car system.

WALNUT, IA.—The City Council has adopted plans for a $14,000 electric light plant.

NEW ORLEANS, LA.—The charter of the New Electric Light Company has been approved by the City Council, and it has been authorized to do business in this city.

WORCESTER, MASS.—It is reported in financial circles in this city that a syndicate of capitalists has been organized to acquire control of the electric lighting and gas business throughout the western part of Worcester County, from Worcester to Palmer.

BENTON HARBOR, MICH.—The City Council has let a contract for lighting the city to the Benton Harbor & St. Joseph Electric Light Company. The company will supply 125 1200-cp arc lights at $47 per annum each, this being a reduction from $70 each.

KOOCHICHING, MINN.—The Village Council is calling for bids to install a municipal electric light plant.

STILLWATER, MINN.—It is reported that the Stillwater Gas and Electric Company will make surveys and plans for a new dam in connection with a power house. The work complete will cost $200,000.

CLINTON, MISS.—The citizens have voted to issue bonds for the construction of water works and an electric light plant.

ST. LOUIS, MO.—The Anheuser-Busch Brewing Association has contracted for two 200-kw turbo-generator units for its plant in this city.

STANBERRY, MO.—The Stanberry Electric Light Company has been incorporated with a capital stock of $25,000, all paid in. The incorporators are: James T. Norman, Alvin C. Frisbie and Thomas D. Hussey.

COLUMBIA, MO.—A special election has been called by the City Council to vote on the proposition to issue bonds for $100,000 for the purchase of the waterworks and the electric light plant belonging to the Columbia Water & Light Company. The plant has been appraised at $67,000 by a board of commissioners, and that amount will be paid for the plant, the remainder being used in installing a system of deep wells.

JERSEY CITY, N. J.—The Monterey Light & Power Company has been incorporated; capital, $500,000. Incorporators: Kenneth K. McLaren, Robert L. Hogust and Roger H. Williams.

JAMESTOWN, N. Y.—The Warren Electric and Manufacturing Company has secured the contract for machinery for the municipal electric light plant for $8000.

MOORESVILLE, N. C.—B. A. Troutman, of Mooresville, is the promoter of a stock company which expects to build an electric light plant in this town.

SALISBURY, N. C.—The Salisbury electric light and gas plants have been sold to the Salisbury-Spencer Light and Railway Company. The electric plant will be used in the operation of the street railway now under construction.

RICHWOOD, OHIO.—The Richwood Light, Heat & Power Company, capital $30,000, has been incorporated by O. P. Lenox, L. G. Peet, B. Cahill, J. F. Wood and L. P. Albright. The company will purchase the lighting plant now owned by E. A. Schambs, and will add to the equipment and extend the service.

COLUMBUS, OHIO.—The Indianola Heating & Lighting Company and the Public Service Company have agreed on a consolidation. The former operates a lighting and heating plant on the North Side, and the latter is building a similar plant on the West Side. The capital of the new company will be $1,500,000. A. W. Field, who has been manager of the Columbus Railway & Light Company, is slated for manager of the consolidated company.

GROVE CITY, PA.—J. W. Russell, Jr., Borough Secretary, writes that the borough will probably construct a municipal electric light plant.

WILKESBARRE, PA.—The City Council has granted franchises to the Ashley Electric Light Company and the West Side Electric Light Company.

NEW CASTLE, PA.—The town has decided to erect a municipal lighting plant, and contracts for material will be closed at once. At present the Mahoning Valley Railway Company lights the town.

NASHVILLE, TENN.—It is reported that Meiklebam, Dunsmore & Ackerman, of New York, have agreed to take $2,000,000 of the stock and bonds of the Great Falls Power Company which, it is stated, will shortly begin the work of developing the Caney Fork falls near Nashville, where a minimum of 2000 hp is available. The concern proposes to supply power and light to many towns in central Tennessee.

WILLS' POINT, TEX.—The Wills' Point Electric Light Company has filed letters of incorporation, with a capital stock of $10,000. The incorporators are: O. I. Johnson, Charles E. Brown and W. B. Rogers.

NEWPORT NEWS, VA.—The Newport News Shipbuilding & Dry Dock Company contemplates the building of a plant for manufacturing electrical equipment for ships.

ELLENSBURG, WASH.—A special election has been held here, at which the citizens voted favorably upon the proposition of bonding the city for $20,000 for an electric power and lighting plant.

MONTICELLO, WIS.—E. L. Bables is reported interested in the construction of a lighting plant.

SHEBOYGAN, WIS.—The Sheboygan Light, Power & Railway Company has passed into the control of the Construction Company of America, which is building the interurban railway to Plymouth.

WHITEHALL, WIS.—As a result of the washing away of a portion of the mill-dam, this village is now without electric light. There are no prospects of resumption until warm weather sets in.

SHERBROOKE, QUE.—The Sherbrooke Heat, Light & Power Company has made a proposition to the Council of the city of Sherbrooke that if the company is granted a contract for 15 years, it will give a reduction on the flat rate of 16-cp lamps from $6 to $5, and an equal share of the net profits. It is expected that this proposition will be turned down, as the municipal ownership party claims that as the company is only able to pay 4 per cent. there would be little left for division. It is understood that if the electric company does not accept the city's offer of $200,000 for electric light and gas plants, that a company will be formed and electric light supplied the city at a minimum figure.

THE ELECTRIC RAILWAY.

MOBILE, ALA.—The Mobile Light & Railroad Company will apply to the board of revenue of Mobile County for the right to extend the Whistler branch from Pritchard Station to Magazine Point.

BIRMINGHAM, ALA.—The annual meeting of the Birmingham Railway, Light & Power Company was held at the offices of the company in Birmingham. The officers now are: Robert Jemison, president; W. A. Walker and J. A. Emery, vice-presidents; J. P. Ross, secretary; C. O. Simpson, treasurer and auditor; J. A. Emery, general manager.

LOS ANGELES, CAL.—Abbot Kinney, who, with the old Los Angeles Traction Company, was engaged in building an electric railway from this city to Santa Monica in opposition to the Los Angeles-Pacific Railroad Company, has sold his interest to Gen. M. H. Sherman and E. P. Clark, of the Los Angeles-Pacific Company, for $280,000.

DENVER, COL.—Under a final decree issued by Judge Hallett, in the United States Court, all the holdings of the Denver, Lakewood & Golden Railway will be sold within 60 days for the benefit of creditors. There is due, according to the decree, to the holders of 627 outstanding bonds of the company, for principal and interest, the sum of $1,016,060, no part of which has been paid. The court has appointed a special master, who will take charge of the sale and report to the receiver and to the court.

NEW LONDON, CONN.—The Groton & Stonington Street Railway Company is perfecting arrangements for beginning the construction of its proposed road as soon as the weather moderates.

CHICAGO, ILL.—The Aurora, Elgin & Chicago Railway is about to issue second mortgage bonds to the amount of $500,000.

BELLEVILLE, ILL.—Attorney Charles A. Karch has received word from President J. R. Piercy and Chief Engineer Isaac C. Smith, of the Southern Illinois Electric Railway, which will build a line from Salem, Ill., to Belleville, where it will connect with the East St. Louis & Suburban, that they have been successful in disposing of their bonds to a New York firm, and that the work now under way will be pushed so as to have the lines in operation by July 1.

INDIANAPOLIS, IND.—The Marion County Construction Company, organized to construct and build electric and steam railroads, and other public works has increased its capital stock $25,000. C. E. Haugh is president and W. C. Smith, secretary.

COUNCIL BLUFFS, IA.—The City Council has voted to grant a franchise ordinance to the Council Bluffs, Tabor & Southern Electric Railway.

ARKANSAS CITY, KAN.—L. H. P. Northrup, who was given a franchise to build an electric railway in this city and an interurban road between Arkansas City and Winfield, and Arkansas City and Chilocco, has employed Thomas V. Hall & Company, consulting engineers, to survey the line.

HOPKINSVILLE, KY.—The Southern Kentucky Interurban & Traction Company is said to be contemplating the building of an electric railway from Hopkinsville to Franklin, Ky.

LEXINGTON, KY.—The plan of Cincinnati, Hamilton and other Ohio capital to construct an electric railway from Lexington, Ky., to Frankfort, Ky., a distance of some 30 miles, has been revived.

LOUISVILLE, KY.—The Louisville & Southern Indiana Traction Company is offering to float $250,000 5 per cent. first mortgage gold bonds, to be used in building into Louisville. The common stock of the company is $2,000,000 and the preferred stock is $1,000,000. The trustees of the new issue are the American Trust & Savings Bank, of Chicago, and the United States Trust Company, of Louisville.

BOSTON, MASS.—The Newton Street Railway Company has petitioned the railroad commissioners for authority to issue $250,000 5 per cent. coupon bonds, par value $500 each, the same to be used for additional extensions and equipment.

WORCESTER, MASS.—A petition has been filed in the State Legislature by the Worcester Consolidated Street Railway Company for authority to build an extension to its lines through West Boylston and Sterling, connecting Worcester and Leominister.

BOSTON, MASS.—The railroad commissioners have given their approval of the sale of the Framingham, Southboro & Marlboro Street Railway Company to the Boston & Worcester Street Railway Company, and have authorized the latter company to issue 1850 new shares to consummate the sale, the said new shares to be exchanged share for share for the capital stock of the Framingham, Southboro & Marlboro Street Railway.

DETROIT, MICH.—The Detroit United Railway Company will likely build an electric belt line to handle freight. The idea is to have an electric belt line upon which freight coming into Detroit can be handled, thus relieving the freight traffic on streets now crowded with passenger traffic.

TRENTON, N. J.—The Trenton Street Railway Company is installing an 800-kw generator in its power house. Additional boilers will be installed later, and the company proposes having practically a duplicate set of generating machinery, so that there will be little danger of a tie-up from accidents.

ALBANY, N. Y.—The Ithaca-Cortland Traction Company has been authorized to issue a mortgage for $650,000 for construction work.

ALBANY, N. Y.—The State Railroad Commission has given authority to the Central Long Island Electric Railway to issue a mortgage on its property for $500,000. It is proposed to build a line from Port Jefferson to Patchogue.

NIAGARA FALLS, N. Y.—The Electric City Railway Company has been incorporated to build a line eight miles long. The capital stock is $80,000 and the directors are Alvah K. Potter, Lockport; James S. Simmons and Frederick J. Brown, Niagara Falls.

NEW YORK, N. Y.—The Interborough Rapid Transit Company has ordered 200 steel cars for use in the subway. The cars will be delivered in the spring for use as soon as the road is opened to traffic. The new cars are to be 51 ft. 2 ins. long, including platforms, 12 ft. high from rail to roof, and 8 ft. 7 ins. wide over the sheathing. The interiors will have a aluminum finish. The seats will be of metal.

MARION, OHIO.—The Findlay, Forest & Marion Railway Company has been incorporated, with $10,000 capital stock, by Claude Meeker, Walter B. Beebee, H. E. Armbruster, M. B. Earnhart and William A. Morrison.

WARREN, OHIO.—The Warren, Cortland & Jefferson Traction Company has been incorporated, with a capital stock of $10,000. The incorporators are: John Lundy, P. N. Taylor, A. H. Gebert, J. L. Morgan and Geo. Pomeroy.

WILKESBARRE, PA.—There is talk of building a third-rail electric railway from White Haven to Wilkesbarre.

NEWHOPE, PA.—The Trenton, Newhope & Lambertville Street Railway Company has secured an option on the Newhope-Delaware Bridge, which is being constructed between this borough and the city of Lambertville, N. J. The company, which is connected with the New Jersey & Pennsylvania Traction Company and the Yardley, Morrisville & Trenton Street Railway Company, has a charter for a line from Yardley to this place, and it is understood that construction will begin in the spring.

LANGHORNE, PA.,—William B. Parry, who built the Newtown, Langhorne & Bristol Street Railway, and who has been actively interested in the movement to connect Philadelphia, Langhorne and Trenton by a direct electric railway, has secured rights of way over most of the route lying between Langhorne and Willow Grove. Private right of way has been secured, as far as possible, and the proposed line extends from this borough to Somerton, Philadelphia, thence to Bethayres, Alnwick Park, Heaton and Willow Grove, where connections would be made with the Philadelphia Rapid Transit lines for Philadelphia and Doylestown.

CORSICANA, TEX.—The Corsicana Traction Company has increased its capital stock from $100,000 to $125,000. It is reported that the company will make important improvements and will extend its system.

MEMPHIS, TENN.—The location of the line of the Shelby Traction Company of Memphis has been determined, and estimates are now being made for the construction of the twenty-mile line.

OGDEN, UTAH.—The La Porte Construction Company of La Porte, Ind., has been awarded the contract for the construction of the Burns-Bamberger road between Farmington and this city. The Salt Lake and Ogden Railway road extending from Salt Lake to Farmington will be converted into an electric system. The work is to be completed within ten months and will be commenced some time in March. About $5,000,000 will be expended on the proposed work.

NEWPORT NEWS, VA.—The directors of the Newport News & Old Point Railway & Electric Company have elected officers for the ensuing year as follows: President, William J. Payne; vice-president, Geo. A. Schmelz; treasurer, Henry A. L. Schmelz; secretary, D. C. Zollicoffer; general manager, H. H. Carr.

NORFOLK, VA.—Judge Waddill, in the United States Court, has granted the petition of the receivers of the Bay Shore Terminal Company to issue receivers' certificates to the amount of $150,000, which funds will be used by the company to complete its electric railway system through from the business parts of Norfolk to Ocean View.

DAVENPORT, WASH.—The Adams County Electric and Transit Company has decided to extend its system from this city to Crystal City, a distance of about twenty-six miles.

APPLETON, WIS.—W. H. Holcomb, J. A. Hayes, John L. Jacqet and Paul V. Cary have incorporated as the Outagamie Traction Company to build an electric railway between Appleton, Hortonville and other cities. The necessary franchises have nearly all been secured.

ROSSLAND, B. C.—MacDonald and Winn, of this place, are seeking incorporation for a company to build a line of electric railway from Crawford Bay on Kootenay Lake to a point near Fort Steele, East Kootenay district.

BRANTFORD, ONT.—Application will be made to the Parliament for a charter incorporating an electric railway from Thorold south to Port Colborne, east to Fort Erie, westerly through the counties of Welland and Haldimand to Brantford.

WALKERTOWN, ONT.—The Walkertown & Lucknow Railway Company is seeking incorporation to build a line of electric railway from this town to the village of Lucknow. A. H. Macdonald, of Guelph, is solicitor for the applicants.

GUELPH, ONT.—The Guelph Junction Railway Company will ask incorporation to build a line from Guelph to Goderich, with a branch to Listowel and another branch to St. Mary's and Clinton, via Stratford, with power to lease or sell to the Canadian Pacific Railway. Electric power will be used.

WINNIPEG, ONT.—Messrs. Campbell, Pitblado, Hoskin and Grundy, of Winnipeg, give notice of an application to the Manitoba Parliament for an act to incorporate a company to build and operate an electric railway and telegraph and telephone lines within a radius of 75 miles of Emerson, in the Province of Manitoba. Permission is also sought to construct and maintain a water power development on the Roseau River.

OTTAWA, ONT.—At the coming session of Dominion Parliament a company, in course of organization, will apply for a charter to construct an electric railway from Ottawa to Buckingham, thence up the Leivre River to a point on the line of the proposed Grand Trunk Pacific Railway, and on to James Bay. The names of those interested in this enterprise are withheld at present, but it is understood they comprise Ottawa and Montreal capitalists.

QUEBEC, QUE.—A project is under way to connect with the city of Quebec by means of an electric railway, a number of parishes surrounding that city. A company has been formed and application will be made to the Provincial Legislature for a charter. The capital of the new company will be placed at $100,000.

NEW INDUSTRIAL COMPANIES.

THE ALPHA COMPANY, of Cleveland, Ohio, has been incorporated with a capital stock of $25,000, to construct power plants.

THE NATIONAL TELEPHONE CONSTRUCTION COMPANY has been incorporated at Chicago with a capital stock of $2500. The directors are E. J. Phillips, G. A. Herrick and others.

THE HARPER ELECTRICAL COMPANY, of Fort Wayne, Ind., has filed articles of incorporation. The company proposes to manufacture electrical supplies. Raymond and Joseph Harper and others are the promoters.

THE DRAWBAUGH PATENTS COMPANY has been incorporated in Jersey City, N. J., with a capital stock of $40,000. The incorporators are Leo J. Matty, Emilius W. Scherr and Herbert G. Ogden.

THE ELECTRIC BURGLAR ALARM & DEVICE COMPANY has been incorporated in Washington, D. C., with a capital stock of $60,000. The names of the incorporators are: G. M. Walker, J. E. Crandall and C. H. Neely.

THE MISSOURI AUTOMOBILE WORKS, St. Louis, Mo., with a capital stock of $10,000, one-half paid, has been incorporated. The shareholders are: Robert N. Collins, Christopher W. Johnson, Cyrus W. Haas, A. T. W. Pritchett and L. P. Graffmann.

THE GISSON-SHORT CYCLE AND AUTOMOBILE COMPANY, of Indianapolis, Ind., has incorporated with an initial capital of $10,000. This amount will be increased soon. The company will manufacture and sell automobiles, repair bicycles and automobiles, motor vehicles, etc. W. H. Brown, C. E. Short and C. E. Gibson are the incorporators.

THE STERLING ELECTRIC COMPANY, of Lafayette, Ind., has increased its capitalization $100,000. This money will be used for improving and enlarging the plant in order to take care of the company's rapidly increasing business. The officials deny the report that the company or plant is to be consolidated with Kellogg Switchboard and Supply Company, of Chicago.

LEGAL.

"HOW OLD IS ANN?"—"How old is Ann?" is a question that the Supreme Court of Virginia must decide. It came up recently at Richmond in the case of Northington vs. the Norfolk Railway & Light Company. The age of Miss Ann Northington, of Norfolk, when she signed a certain conveyance is in doubt. One side of the controversy contends that she was eighteen, while the other says she was twenty-three. When one of the attorneys stated that the proposition was "How old is Ann?" there was a burst of laughter, in which the court was compelled to join. It became apparent, however, that it was no joking matter, and that upon the decision of the court depends who will receive a large sum of money.

WAGNER MOTORS AND TRANSFORMERS.—Judge Adams, of the United States Circuit Court, St. Louis, handed down decisions in two important patent cases Saturday, February 13. One was the General Electric Company against the Wagner Electric Manufacturing Company, of St. Louis, for infringing a patent on electric motors. This was a motion for preliminary injunction. The court denied the injunction. The other case was brought by the Westinghouse Electric & Manufacturing Company against the Wagner Electric & Manufacturing Company, for manufacturing electrical transformers. Suit was brought on a patent granted to George Westinghouse, Jr. The court in this case decided that the transformer manufactured by the Wagner Company was no infringement of the patent sued on.

TELEPHONE AND EMINENT DOMAIN.—In Kirby vs. Citizens' Telephone Company of Sioux Falls, S. D., the question came up whether the erection of a telephone system in the streets of a city constituted an additional servitude. Upon appeal, the Supreme Court of South Dakota sustained the vacating of a preliminary injunction against the telephone company. Its points were: 1. Const. Art. 6, Sec. 13, providing that private property shall not be taken or damaged for public use without just compensation, and that the fee of land taken for highways shall remain in the owner, and Article 17, Sec. 18, providing that compensation shall be made before property is taken or injured, do not apply to the use of the streets of a city for the purposes for which they have been dedicated. 2. Under the direct provisions of Laws 1885, p. 208, c. 141, Sec. 3 (Rev. Civ. Code 1903, Sec. 554), a city may permit a telephone company to erect poles and maintain a telephone system on its streets. 3. The construction, maintenance, and operation of a telephone system on the streets of a city in such a manner as not to cause unnecessary injury or inconvenience to property owners is not an additional servitude for which an abutting owner is entitled to compensation.

ACCIDENT FROM CONDUIT WORK IN STREET.—The case of Leavitt vs. New England Telephone Company was settled recently by the Supreme Court of New Hampshire. In an action against the telephone company for injuries caused in passing over a sidewalk at a place where an excavation had been made by defendant, under license from the city, plaintiff's claim was that defendant was liable for the injuries without regard to the fact that the city had done part of the work of filling the excavation. Plaintiff offered no exceptions to the court's charge, but merely excepted to the admission of evidence in substantiation of the defendant's theory that, the city having completed the filling of the excavation, defendant was not liable. It was held on an appeal that plaintiff could not obtain a reversal on the theory that defendant's evidence was irrelevant, but should have excepted to the charge. The remarks of defendant's counsel to the effect that the concreting over the excavation was done for the city, and when defendant was stopped in its work by the superintendent of streets its liability ceased, furnished no ground for setting aside the verdict, as the statements of fact were supported by evidence, and the statements of law, if erroneous, would be deemed to have been corrected by instructions.

PERSONAL.

H. L. WEBB.

MR. HERBERT LAWS WEBB.—All the American friends of Mr. Herbert Laws Webb will be interested to know that after several years of residence in this country he has decided to take up his abode permanently in England, his native land. Mr. Webb has been connected with the development of electrical industries from his earliest youth, being a member of the well-known Webb family so prominent in submarine cable development in England in the last century, and one of whom was formerly secretary of the English Institution of Electrical Engineers. Mr. Webb is also a nephew of Sir W. H. Preece, F. R. S. As an electrical engineer Mr. Webb has been actively engaged in the practice of his profession since 1889, and before he came to the United States he had devoted his attention to submarine cable work. While in this country he gave his attention chiefly to telephonic development, although for a short period in 1892 he was editor of *Electricity* at the time that paper started. For several years past he was engaged as a member of the expert staff of the New York Telephone Company, for whom he made three trips to Europe on inspection work, as well as for the American Bell Telephone Company. For about a year past Mr. Webb has been in England as an expert connected with the Buckingham automatic telegraph system and in connection with telephonic work. In 1897 he gave evidence at the well-remembered Glasgow telephone inquiry and since that time has been called into other investigations of the same character. He is the author of an excellent guide to cable testing, etc., and of an admirable little telephone handbook which has had a wide circulation. To the electrical and general press and particularly to these columns, as well as to the magazines, he has contributed numerous articles on electrical subjects, chiefly of a telephonic nature. In resuming residence in London, Mr. Webb is making his headquarters at 8 Queen Anne's Gate, but he will shortly be moving into larger quarters where he will engage in the practice of consulting electrical engineer, giving special attention to telephonic work. The best wishes of his American friends follow him back to the old country, whither he returned during the last week or two.

MR. A. A. KNUDSON, the specialist on the subject, lectured before the Franklin Institute, Philadelphia, last week, on the corrosion of metals underground by electrolysis.

MR. W. H. BASSETT, of Jefferson City, Mo., has been appointed auditor and traffic manager of the Kinlock Telephone Company, of St. Louis, with headquarters at Jefferson City.

MR. P. LETHEULE, of the French Thomson-Houston Company, has been appointed by the French Government engineer of the French Department of Electricity at the St. Louis Exposition.

PROF. FRANK G. BAUM has resigned from the electrical engineering department of Stanford University to accept the post of electrical engineer for the California Gas & Electric Company, in connection with the Bays Counties and Valley transmission plants.

MR. LOUIS ALBERGER, of the Alberger Condenser Company, White Building, New York, who has been absent from his office for some three weeks past owing to indisposition, has gone for a trip to Cuba to look over the business situation in that part of the world.

MR. WILLIAM E. GAVIT has been elected vice-president of the old American Institute of New York, in whose spacious rooms and building the New York Electrical Society holds so many of its meetings. In this respect Mr. Gavit has been an active and influential friend of the Society.

MR. DOUGLASS BURNETT has been elected general manager of the United Electric Light & Power Company, of Baltimore, Md. Mr. Burnett has been identified with the New York Edison Company since 1894, and is a member of the American Institute of Electrical Engineers and of the New York Electrical Society.

MR. W. D. BALDWIN, president of the Otis Elevator Company, White Court Building, New York, has returned from a trip to Europe, whither he recently went in connection with the contract for the large passenger "lifts" to be installed in the London underground railroad system now being constructed by the Charles T. Yerkes syndicate.

MR. CAMERON FORBES, a member of an old Boston family well known in connection with Bell telephone history and development, and who has been prominently connected with the electrical firm of Stone & Webster since graduating at Harvard, has been offered by President Roosevelt an appointment as one of the commissioners for the Philippine Islands. He has accepted.

PRESIDENT H. S. PRITCHETT, of the Massachusetts Institute of Technology, while in Germany recently, spent some time studying the experimental electric road in the environs of Berlin upon which the uniform high speed of from 100 to 130 miles an hour is maintained. He will have an interesting account of his impressions in *McClure's Magazine* for March.

MR. J. H. WAUGH, of Pittsburg, Pa., has severed his connection with the Westinghouse Electric & Manufacturing Company and has assumed the active management of the business of the Electrical Equipment & Supply Company, of that city. This latter company has just been chartered under the laws of Pennsylvania, with a capital stock of $60,000. President Waugh is greatly encouraged as he starts out, business developing rapidly, with inquiries from all over the Union.

MR. JOHN F. KELLY, of the Stanley interests and president of the John F. Kelly Engineering Company, Singer Building, New York, has gone to

Milwaukee in connection with the development of the plans of the Allis-Chalmers Company, which concern, as mentioned in our last issue, is to enter into the manufacture of electrical machinery on an extensive scale.

MR. PUTNAM A. BATES, assistant secretary and sales manager of the Crocker-Wheeler Company, announces that he has resigned his position and will retire from that company on March 1 next. Mr. Bates has formed a partnership with Mr. John Neilson, who was until recently assistant secretary and assistant treasurer of the New York & Stamford Electric Railway, and under the firm name of Bates & Neilson, will conduct a general practice of consulting electrical engineering, with offices in New York City.

OBITUARY.

MR. ERASTUS WIMAN, of Staten Island, N. Y., died last week. He was at one time very active in electrical matters, especially telegraphy, and later on took up the development of electrical lighting with equal energy, establishing a large plant on Staten Island where he introduced also the alternating-current system for the streets. His electric fountain displays are well remembered by New Yorkers. Deceased was born in Churchville, Ont., in 1834.

H. W. OLIVER.—Mr. Henry W. Oliver, the well-known iron manufacturer of Pittsburg, died at Alleghany, Pa., on February 9, of a complication of diseases. Mr. Oliver was born in Ireland in 1840, and was brought to Pittsburg when two years of age. He began his business career as a messenger for the old National Telegraph Company at the age of 13, and ultimately became president of one of the largest iron and steel plants in the country. Mr. Oliver served in the Civil War, and throughout his life was active in politics.

M. A. HANNA.—Senator Marcus A. Hanna, of Ohio, died at Washington, February 15, of typhoid fever, after an illness extending over nearly two months. Deceased was one of the most widely known men in the United States, being prominent in national politics and in large business enterprises in Cleveland, which was his home. Senator Hanna was prominently identified with the street railway development in Cleveland, and at the time of his death was a director of the Cleveland Electric Railway Company. He was born in New Lisbon, O., September 24, 1837, and was consequently in the 67th year of his age. Special funeral services were held in the United States Senate chamber on Wednesday of this week, and the remains were afterwards taken to Cleveland for burial.

Trade Notes.

THE SPRAGUE ELECTRIC COMPANY has just issued a bulletin devoted to the W. L. engine type of direct-current generators, illustrating and describing them.

THE SPRAGUE ELECTRIC COMPANY announces that its Baltimore office, which was destroyed in the recent fire, is now located in the Maryland National Bank Building.

HADAWAY ELEC. HEATING & ENG. COMPANY, of New York City, announces that it has moved its offices to Room 322, No. 136 Liberty St. It has doubled its shop capacity, and is now able to take care of a large business.

CROCKER-WHEELER COMPANY, of Ampere, N. J., announces that its Chicago office has established headquarters for Western Ohio, at No. 1232 Union Trust Building, Cincinnati, O., with Mr. H. A. Brown as representative.

THE ELECTRIC PORCELAIN COMPANY, East Liverpool, O., has planned to make an addition to its already large plant, to cost $16,000. This extension is necessary in order to supply the rapidly growing demand for this company's goods.

THE ELECTRIC STORAGE BATTERY COMPANY.—Owing to the fire in Baltimore, the Electric Storage Battery Company has removed its Baltimore office to Philadelphia, and until further notice it will be at the headquarters, Allegheny Avenue and Nineteenth Street.

THE DOWNWARD LIGHT ELECTRIC COMPANY, 225 Fourth Ave., New York, has found its increasing business so widespread that it has been deemed advisable to open a branch office in Philadelphia. This is located in the Witherspoon Bldg.

C. & C. ELECTRIC COMPANY, 143 Liberty St., New York, has recently issued several bulletins, both quite voluminous, one giving a list of some users of its various generators and motors, and the other being devoted to illustrations and description, etc., of its "M. P." machines, direct-current, so well and widely known. Applications of the apparatus are shown, as well as details of construction.

ELECTRICAL MATERIAL COMPANY, of Baltimore, Md., informs us that it was fortunate enough to escape damage direct, from the recent great fire. Under the circumstances, it now looks naturally for a very large increase in business, and has decided to more than double its stock to take care of the inrush of orders. It is now in a better position than ever to make immediate shipments.

THE NERNST LAMP COMPANY, in accordance with its new policy of establishing district offices in the large cities, has recently opened an office at 47 State St., Detroit, Mich., and appointed Mr. Charles F. Case as district sales manager of it. The territory embraced by this office is the lower peninsula of the State of Michigan, the northwestern part of Ohio and the northeastern part of Indiana.

VIADUCT MANUFACTURING COMPANY.—We are glad to note that the great fire at Baltimore, Md., did not reach the offices of the Viaduct Manufacturing Company, of that city, whose factory, being located ten miles out at Relay, is also still in full blast, turning out large quantities of telephones, district messenger boxes, Skirrow switchboards, resonators, etc. All orders are being attended to with prompt dispatch.

THE REEVES ENGINE COMPANY, New York, whose product has met with such phenomenal success, is now in a position to entertain establishing selling agencies throughout the United States and foreign countries. Its manufacturing facilities have been so materially increased that it is able to make prompt deliveries, and will be pleased to hear from capable people desiring to avail themselves of this excellent opportunity. Its sales office is at 85 Liberty St., New York.

THE "TALKING" SIGN.—The Mason Monogram Company, 280 Broadway, New York, has issued a unique card regarding its electric "talking" signs. The card contains a night view of a store over which is one of these signs. In the card is a slit, under which a circular card is moved about its centre. On being turned words are brought under the slot, reproducing the effects of the actual sign. It is an excellent idea and shows in very compact form just how these signs produce the results claimed for them. The utility of the card is made greater by the addition of a neat little monthly calendar attached to one corner.

TURBINE ENGINEERING COMPANY.—This concern, of West Troy, N. Y., and Whitehall Building, Battery Place, New York, calls attention to its hydraulic power department at the former address. It acts as engineer and contractor for complete hydraulic power plants, and states that its relations with the manufacturers of the equipment used in such plants is of a character that places it in a peculiarly advantageous position for carrying out such work. It takes the contract for the entire plant, with all the consequent benefits to the purchaser dealt with. The officers are: A. M. Young, president; H. G. Runkle, vice-president; M. J. Warner, treasurer; F. A. Curtiss, secretary; L. G. Read, general manager; J. Sturgess, manager of the hydraulic department.

EUREKA TEMPERED COPPER.—The Eureka Tempered Copper Works, North East, Pa., have just issued their 1904 catalogue and price list of their copper and brass products for all purposes. The list is a very complete one and includes commutator bars and commutators for machines of all the standard makes; trolley harps; trolley wheels; brushes; switches, etc., a code word being given for each size and make. Besides this there are several tables of value in making calculations and estimates. At the back of the book are several numbered pages perforated, which are to be torn out and replaced by sheets of corresponding numbers when received from the works. The catalogue is gotten up in an excellent manner, and is well illustrated. It shows great painstaking and care in its production. The Eureka works are among the oldest in the business, and their long experience has placed the concern in a position to produce the best goods possible.

Record of Electrical Patents.

UNITED STATES PATENTS ISSUED FEBRUARY 9, 1904.

[Conducted by Wm. A. Rosenbaum, Patent Attorney, 140 Nassau St., New York.]

750,309. ANNUNCIATOR; Lambert Schmidt, Weehawken, N. J. App. filed Aug. 28, 1901. (See page 365.)

751,440. COMMUTATOR LEAD AND MODE OF MAKING SAME; Charles F. Adams, Pittsfield, Mass. App. filed Aug. 8, 1903. A flat copper strip is folded lengthwise and slit along the fold at one end so that the members may be bowed outward to embrace the conductor, the opposite end going into the commutator bar.

751,441. MEANS FOR PROTECTION AGAINST REVERSE CURRENTS; Leonard Andrews, Manchester, England. App. filed June 25, 1903. Two magnetic circuits are energized respectively by a shunt and a series winding, two secondary windings are arranged to be excited by the magnetic circuits and to operate a circuit-controlling magnet.

751,442. REVERSE CURRENT CUT-OUT; Leonard Andrews, Manchester, England. App. filed June 25, 1903. A closed magnetic circuit carrying two coils and an open magnetic circuit shunting both parts of the closed circuit on which said coils are wound, the open circuit including a reciprocating member which actuates a switch.

751,459. LINE INSULATOR; Cummings C. Chesney, Pittsfield, Mass. App. filed Jan. 14, 1903. An H-shaped insulating support composed of a plurality of insulators set at an angle to each other.

751,460. LIGHTNING ARRESTER; Cummings C. Chesney, Pittsfield, Mass. App. filed Aug. 8, 1903. The earth wire includes a solenoid coil and an air gap, the latter being opened by the energizing of the coil.

751,474. POLE CHANGER FOR DYNAMOS; Isidor Deutsch, Montreal, Canada. App. filed May 14, 1903. Details.

751,501. ELECTRIC TELEPHONE; Ernst Gundlach, Western Springs, Ill. App. filed Nov. 10, 1902. (See page 365.)

751,527. APPARATUS FOR DIVIDING, SEVERING AND SIMILARLY TREATING CLOTH; Alexander Marr, Manchester, England. App. filed June 5, 1903. Electrically heated wires are arranged upon the surface of a drum, and the drum rolled over the cloth to sever it along lines corresponding to the position of the wires.

751,539. RINGING-KEY FOR TELEPHONE-SWITCHBOARDS; Frank R. McBerty, Evanston, Ill. App. filed May 9, 1902. (See page 365.)

751,547. MOTOR CONTROLLER; Francis V. Nichols, Pittsfield, Mass. App. filed June 13, 1903. Improvements directed towards reduction in size and simplicity.

751,549. SYSTEM OF ELECTRICAL DISTRIBUTION; John S. Peck, Pittsburg, Pa. App. filed May 1, 1903. A plurality of compound-wound rotary converters adapted for operation in parallel, a bank of transformers each having a plurality of secondary windings so arranged that the number of rotary converters connected thereto may be varied without varying the compounding effect upon the direct-current circuit supplied thereby.

751,563. DYNAMO ELECTRIC MACHINE; David B. Rushmore, Pittsfield, Mass. App. filed June 26, 1903. The internal shape of the field coil is different from the external shape of the core which it surrounds, to produce ventilating spaces.

751,566. RINGING-KEY FOR TELEPHONE-SWITCHBOARDS; Charles E. Scribner, Chicago, Ill. App. filed May 9, 1902. (See page 365.)

751,571. TIME LIMIT RELAY FOR ELECTRIC CIRCUITS; Harve R. Stuart and Arthur B. Reynders, Wilkesbarre, Pa. App. filed April 11, 1903. A time limit relay for electric circuits, comprising two contact members, mechanical devices for operating one of them to close the relay circuit, electro-magnetic devices for releasing that member, a retarding device and means for varying the length of the path through which the movable member travels.

751,574. ELECTRIC SPARK-PRODUCING APPARATUS; Chester H. Thordarson, Chicago, Ill. App. filed March 10, 1903. Details of construction of a vibrator wherein the breaking of the circuit is accomplished by a sharp hammer-blow, the force of which may be adjusted.

751,581. CONTROLLING MECHANISM FOR ELECTRIC VEHICLES; Frank S. Wahl, Buffalo, N. Y. App. filed Dec. 21, 1901. Details.

751,595. PARALLEL FEEDER PROTECTION; Leonard Wilson, Pittsfield, Mass. App. filed July 16, 1903. A plurality of parallel feeders and a choke coil for each feeder having one winding energized by the current in its feeder and a second winding opposing the first and energized by the sum of the currents in all the feeders.

751,597. ELECTRIC SWITCH; Gilbert Wright and Harold C. White, Pittsfield, Mass. App. filed June 13, 1903. Details of a quick-acting switch.

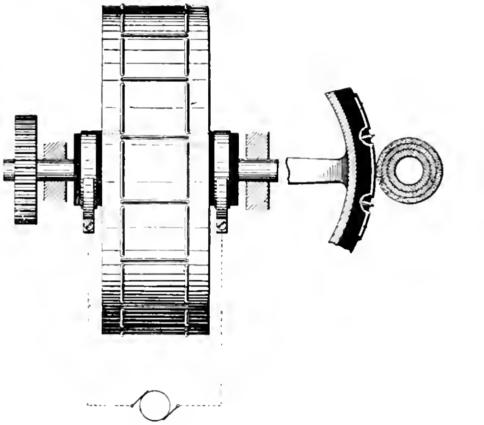
751,598. MEANS FOR CONTROLLING GOVERNOR MOTORS; Gilbert Wright, Pittsfield, Mass. App. filed Sept. 24, 1903. A switch consisting of a handle mounted upon the end of spring plates arranged mid-way between two sets of contacts, so that by hand-manipulation the center plates can be thrown to one side or the other and held as long as desired to impart a corresponding rotary impulse in one direction or the other to a motor.

751,616. MAGNETO-ELECTRIC GENERATOR; Hugh J. Creighton, Anderson, Ind. App. filed May 13, 1903. The magneto is mounted on a base in a manner to yield when inaccuracies of strain occur in the belt.

751,634. RHEOSTAT; George Graybill and John P. Oden, York, Pa. App. filed June 8, 1903. A rheostat for lamp sockets consisting of a rod projecting more or less into a body of granular resistance.

751,638. ATTACHMENT FOR COTTON SEED LINTERS; John W. Harrington, Eastpoint, Ga. App. filed May 2, 1903. A magnetic plate arranged in the throat of the machine to remove bits of iron that may be carried in the body of seeds.

751,654. APPARATUS FOR THE REGULATION OF ELECTRICAL CIRCUITS IN HEATING DEVICES; Willie D. Kilroy, Uxbridge, England. App. filed Oct. 6, 1902. A combined plug and socket operating as a switch in various angular positions.



751,527.—Apparatus for Dividing, Severing and Similarly Treating Cloth.

751,655. TELEPHONY; Isidor Kitsee, Philadelphia, Pa. App. filed Jan. 9, 1901. (See page 365.)

751,664. ELECTRIC INSULATOR; Thomas T. Lyman, Montclair, N. J. App. filed April 4, 1902. An insulator to prevent the formation of electric arcs, composed of asbestos, plaster-of-paris and silicate of soda, vitrified and coated with a waterproofing solution.

751,728. ROTARY SNAP ELECTRIC SWITCH; Monroe Guett, Hartford, Conn. App. filed Sept. 23, 1903. Details.

751,739. INSULATOR; Peter S. Lindal, Edinburg, Pa. App. filed March 31, 1903. Glass plates between which the conductor is held are placed in a box and clamped together by a screw.

751,743. INSULATOR; Joseph M. Mahoney, Boston, Mass. App. filed Dec. 1, 1902. A two-part sleeve having interlocking connections.

751,745. AUTOMATIC SWITCH; Morris Moskowitz, New York, N. Y. App. filed April 8, 1903. Details of a pole-changing switch especially applicable for train-lighting systems in which the generator is subject to frequent reversals in direction of rotation.

751,749. TROLLEY WHEEL; John E. Palmer, Somerville, Mass. App. filed Nov. 14, 1903. Means for retaining the wheel on the wire.

751,750. INDICATING MEANS FOR SNAP ELECTRIC SWITCHES; Charles G. Perkins, Hartford, Conn. App. filed Oct. 29, 1903. A dial supported by and adapted to be rotated on the outside of the cover of the switch.

751,760. ELECTRIC SIGNALING APPARATUS; John E. Stannard, Springfield, Mass. App. filed Feb. 2, 1903. Details.

751,772. STORAGE-BATTERY PLATE; Charles B. Askew, Chicago, Ill. App. filed May 20, 1903.

751,777. FLEXIBLE CONDUIT; Archibald T. Blackler, Malden, Mass. App. filed March 14, 1903. An insulating conduit consisting of a helix composed of smooth, flexible, compact, insulating material, longitudinal strips of a similar character interwoven and one or more longitudinal locking threads.

751,780. ELECTRIC SIGNAL; Harold E. Bradley, Warwick, R. I. App. filed Oct. 3, 1903. The invention comprises the specific devices used in a block system wherein a signal set by one car as it enters the block, is not returned until the last of any number of cars which may also have entered, has passed out.

751,788. ELECTRIC SIGNAL APPARATUS; John M. Golding, Washington, D. C. App. filed July 15, 1903. Means whereby a person desiring to signal another at a different point, may close an electric circuit including the signal at the distant point, which closure will at the same time lock an indicator, which will remain locked until the circuit is broken at the distant point, to notify the sender of the signal that the same has been received.

751,797. CENTRAL-ENERGY TELEPHONE SYSTEM; John Henry Lendi, Chicago, Ill. App. filed Dec. 19, 1900. (See page 365.)

751,803. WIRELESS ELECTRIC APPARATUS ACTING ON TYPEWRITERS; Giuseppe Musso S. Angelo Dei Lombardi, Italy. App. filed Sept. 23, 1902. The electric waves are used to command two disks rotating synchronously at the communicating stations and which are connected with keys of typewriters.

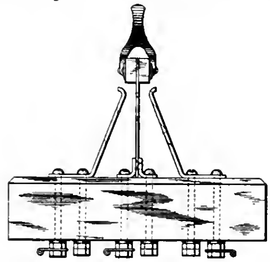
751,816. PROCESS OF WINDING; Arthur J. Strong, Dayton, O. App. filed May 15, 1903. A method of winding wire upon a closed ring.

751,818. ELECTRICALLY-PRODUCED-SOUND INTENSIFIER; Gustaf T. Swenson, San Pedro, Cal. App. filed Dec. 17, 1902. (See page 365.)

751,829. TELEPHONE; Ernest Theodore Billig, New York, N. Y. App. filed Dec. 2, 1902. (See page 365.)

751,830. ARC PREVENTER; Charles E. Blood, Fitchburg, Mass. App. filed Oct. 14, 1903. Air pipes leading to the contacts of the controller are closed and opened at the proper time by the movements of the controller.

751,831. INSULATOR PIN; James H. Bullard, Springfield, Mass. App. filed Aug. 8, 1903. A metal insulator pin comprising a series of webs united near one end and merged into a base at the other.



751,598.—Means for Controlling Governor Motors.

751,839. ELECTRIC HAIR BRUSH; Henry C. Doersch, Nyack, N. Y. App. filed June 1, 1903. Details.

751,854. THERMOSTAT; George D. Hoffman, Chicago, Ill. App. filed May 25, 1903. Details.

751,857. SYSTEM OF ELECTRICAL PROPULSION; Erich Krause, Hoboken, N. J. App. filed Oct. 22, 1903. Solenoids arranged in line with each other and supporting internal rails, cause an armature or car riding upon the rails to be drawn through them.

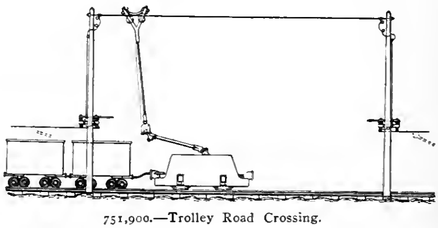
751,886. APPARATUS FOR STERILIZING WATER; Henry Jacques Wessels, Paris, France. App. filed June 22, 1903. (See page 361.)

751,900. TROLLEY ROAD CROSSING; James M. Collins, Byersville, O. App. filed Feb. 2, 1901. At the crossing the trolley wire is raised to an elevation where it will not interfere with crossing traffic and to enable cars to connect with the elevated portion at the crossing, an extension trolley is suspended therefrom and engages with the car trolley while the car moves over the crossing.

751,903. SYSTEM FOR THE OPERATION OF ELECTRIC MOTORS; Arthur C. Eastwood, Cleveland, O. App. filed Sept. 25, 1903. Relates to the construction of the controller for operating the reverse switches and closing the circuit through certain solenoids to cut out the sectional resistance.

751,949. ROAD CROSSING DEVICE; Frank L. Sessions, Columbus, O. App. filed Aug. 8, 1902. A modification of 751,900.

751,974. RAIL CONTACT SHOE AND SUPPORT THEREFOR; George W. Brady and Lawrence R. Jones, Wheaton, Ill. App. filed April 13, 1903. The lips of a straddling shoe which bear against the opposite sides of a third-rail and are hinged and spring-supported, to yield on passing around curves.



751,900.—Trolley Road Crossing.

751,982. SOUND MAGNIFIER FOR RELAYS; Matt A. Hacker, Irvine, Ky. App. filed April 28, 1902. The stroke of the armature is delivered to a diaphragm located at the small end of a megaphone.

751,985. UNDERGROUND CONDUIT INSULATION; John M. Humiston, Berwin, Ill. App. filed April 27, 1903. To diminish electrolysis, sections of non-conducting tubing are inserted at intervals in the metallic tubing.

751,986. APPARATUS FOR PURIFYING LIQUIDS; Otto Kartzmark, Brooklyn, N. Y. App. filed Dec. 26, 1900. (See page 361.)

751,991. CURRENT DIRECTOR; James F. McElroy, Albany, N. Y. App. filed Jan. 28, 1901. A switch having contact fingers in two sets, one used for making and breaking circuit while the other is used for distributing current in two or more circuits.

752,005. ELECTRIC ARC LAMP; Frederick Sindingchristensen, Brooklyn, N. Y. App. filed Aug. 29, 1902. Details of the feed mechanism.

752,008. INDUCTION COIL; Charles F. Splitdorf, New York, N. Y. App. filed July 15, 1902. A thin sheet of hard rubber is wrapped several times around the outside of the primary winding.

Electrical World and Engineer

THE CONSOLIDATION OF "THE ELECTRICAL WORLD" AND "ELECTRICAL ENGINEER."

VOL. XLIII. NEW YORK, SATURDAY, FEBRUARY 27, 1904. No. 9.

ELECTRICAL WORLD AND ENGINEER.

Published weekly by the

McGRAW PUBLISHING CO.

INDEPENDENT TELEPHONE UNION.

It is interesting and encouraging to note that the independent telephone companies in Ohio have again drawn together and reconstituted on an active basis their association. Details of their convention last week are given elsewhere in this issue. One of the most striking things about the convention was its evident friendliness toward co-operation, and in this respect the paper presenting a plan of consolidation is worthy of note. It stands to reason that local telephone service to-day, standing by itself, is not of much account, particularly in regions with scattered population; but while recognizing this truth, the local independent companies have often been very slow to give up their isolation and freedom. It is true that great groups have already been formed, but the subject remains a very live and pressing one.

At the Cincinnati meeting last week a plan was proposed for organizing all toll lines and exchange operating companies. The plan is, to say the least, bold and novel. The group organization, or basic unit, would accept only such members as are not engaged in any contract which would be denied them as members. Members would be required to bind themselves to neither sell to nor enter into any contract with any telephone person, other than a member of the organization. The compulsory power of the organization should be in a body of delegates, sitting in a lower and an upper council. Each company should be represented by a delegate, sitting in both councils. In the upper council he should have a single vote, while in the lower council his vote should be in proportion to the assessed value of the property belonging to the company which he represents. This body should levy necessary taxes, the limit being fixed. The tax levy would originate in the upper council. This body should elect a president to administer affairs in vacation. No money should be paid out except by vote of the council. A referee should be elected, who would settle all controversies between members. All district organizations should be members of the central organization. Its powers should be vested in a body of delegates, one from each district. Sitting in the higher council he should have a single vote, while in the lower council he should have a vote equal to the entire vote in the lower council of his district organization. This body should levy necessary taxes, a limit being fixed. No money should be disbursed except by vote of the council. A president and vice-president should be elected by the council. A referee should be elected who would settle all controversies that might arise between district organizations, or between members of different district organizations. The president should appoint with the consent of the upper council an advisory board, consisting of a director of board of trade, director of patents, director of tolls and such others as might from time to time be advisable. The director of the board of trade should arrange a place for the sale of stock and bonds of member companies. The director of patents should look after patents, to see that members are not taking liability in infringements, and also to buy any new patents of advantage. The director of tolls should establish a clearance house to adjust tolls on messages passing from one district to another. This organization should furnish at a small profit to each member metal plates bearing the copyrighted trade-mark and the words which he would be required to place on each telephone.

This was received with favor, and may prove a foundation for alliance. It is a federal scheme following American political lines, but none the worse for that. The question arises as to how far it can be applied to the management of a business or an industry. A simpler way out, apparently, would be the good—or bad—old plan of regular business consolidation; but this is just what so many of the local independent companies want to avoid.

RECOGNITIONS AND REWARDS.

The recent foundation of the Edison Medal in the American Institute of Electrical Engineers has called attention to the limitations which exist in this country to the recognition and reward of distinguished merit. It is true that the universities and colleges can and do confer honorary degrees upon prominent men from year to year, but aside from that we seem to be lacking in this democracy in power to do that which in Europe, as well in France as in the countries where royalty exists, is done by the head of the nation. We have no Legion of Honor, for example; nor have we a Victorian Order. It interested and pleased a great many of us to note the other day that in connection with the high-speed Zossen work the Emperor William has just decorated Mr. Rathenau and some of the engineers associated with those brilliant experiments. It has also gratified many of us to note that the King of Italy has ordered to be put upon the new postage stamps of that country the heads of Volta and Marconi.

In this country, however, we seem to be reduced to the necessity of founding medals in honor of men while they are still alive, and this may explain a practice which in some respects is not without its dangers and disadvantages. The medals which have been founded to assist in perpetuating the names of John Fritz and Thomas A. Edison, as well as to recognize public service and to stimulate ambitious youth, seem to us admirable illustrations of the manner in which the citizens of a republic can assume the functions of royalty. But it is obvious that the practice should not be and could not be carried very far. Yet failing its extension, we venture to suggest the idea, and feel that we are not undemocratic in doing so, that it would be well if some means existed of expressing to a great man in some tangible lasting form other than a brick house or a loving cup the esteem in which his fellow-countrymen held him and his services.

ELECTRIC HOISTING AT FULL ARMATURE EFFICIENCY.

Our Digest columns this week describe a rather ingenious coupling of two motors by which a wide speed variation is capable of being obtained without more than a single line voltage, and without resorting to rheostatic control in the armature circuit. It is well known that the shunt direct-current motor operates very satisfactorily at constant speed with varying torque. When, however, as in electric hoisting, constant torque has to be provided at variable speed, with frequent stopping and starting, the shunt motor is quite unsuitable, and even the series motor suffers both in range and in efficiency. In the Ward Leonard method the ideal control is obtained at the expense of a triple machine.

In the case described, two shunt motors have their armatures clutched together so as to rotate as one shaft. One of the motors has the usual stationary field frame. The other has its field frame mounted so as to be free to rotate. The hoisting pulley is attached to the latter element. The two armatures are kept constantly running during operations, and when the two fields are equally excited, the movable field magnet remains stationary. By varying the shunt field excitations, however, under the control of a single rheostat, the hoisting pulley can be driven at any velocity from half armature speed forward to half armature speed backward, with no sacrifice of armature efficiency, and with only the increased losses due to a doubled plant and doubled frictions.

Such a combination would be likely to lend itself to small elevator work, since the mechanical and electrical connections would be of the simplest character. Moreover, a single armature and commutator of doubled length might be employed, running through two field systems side by side, one fixed and the other movable. This would form a motor with two fields and one armature, and a motor in which there would be one stator and two rotors. The usual starting devices of a shunt motor would have to be provided, together with a field rheostat with the arm connected to line and the two ends of the rheostat connected to the two field windings respectively. Hence, when the arm stood midway, both fields would be equally excited, but moving the arm in either direction, took resistance out of one field circuit, and added it to the other. By placing the motor in the cellar and the differential field rheostat on the elevator car, the speed of hoisting or lowering should be capable of prompt and close regulation, without, appreciably, affecting the speed of the armature in space. The weakest point of the arrangement is, of course, the duplication of the motor parts, the reduction of output per pound of weight and the increased frictional losses when the relatively massive field frame has to rotate.

THE ENERGY OF RADIUM EMANATION.

In a paper presented by Messrs. Rutherford and Barnes at the last meeting of the American Physical Society, as abstracted in the last number of the *Physical Review*, some very interesting data are given concerning the emanations of radium. It seems that radium and its active salts throw off minute material particles perpetually with enormous velocities. At the same time, a gaseous emanation is released, which is supposed to consist of the deëmanated molecules, or the molecules from which the particles have been projected. The deëmanated molecules in the gaseous emanation undergo a change in the course of a few minutes or hours, and release energy in the process. The change results in a material denominated "emanation X." This emanation X undergoes three more changes in succession, each lasting minutes or hours, each change being accomplished by a further disengagement of radiant energy or heat.

The entire process suggests that the radium atom is unstable, and that, at certain periods of its internal activities, it breaks up or disrupts. As in South American republics, revolutionary movements repeat themselves at regular intervals, and at the crisis the entire structure of an atom undergoes reorganization. This reorganization does not occur at a single transition, but continues through several successive stages, each change reducing the internal energy of the atom, and releasing the superabundant energy which is radiated off. How much internal energy is left in the atom when it resumes business on the lowest plane is not known; but the amount of energy apparently given off in the degradation is stupendous to our minds. The paper states that, from the author's results, one gramme of the radium emanation yields in all stages between two millions and twenty millions of greater calories. We are accustomed to regard the energy of coal, released in combustion, as being relatively large. But coal is reduced to mere ashes by comparison with radium emanation, on the above figures. One gramme of coal liberates in combustion about eight greater calories, or something like a million times less than radium emanation.

To put the results another way, a chunk of coal releases, during combustion, enough energy to lift itself about two thousand miles, or say from New York to Panama, vertically upwards against constant sea-level gravitation. A chunk of hydrogen, our most energetic combustible, releases in combustion an amount of energy capable of lifting itself about four times as far, or to a vertical distance (against sea-level gravitation) roughly equal to the distance from New York to Manila. But a chunk of radium emanation, according to the figures given in the paper, yields without any combustion an amount of energy in the process of its evolution that would lift it against sea-level gravitation not only to the sun, but to the orbit of the planet Neptune, the outside fence post of the solar system, and which is about thirty times further from the sun than the earth is.

Assuming that this is all true, the question suggests itself as to whether the radium atom is a favored atom in its initial energy stock; or, whether other more placid atoms, such as zinc and lead, contain unsuspectedly similar stores of internal energy. In other words, is it just the instability of the radium atom that happens to reveal to us this enormous stock of energy, that would otherwise be beyond our present power to discover, and which other kinds of atoms possess it in a similar degree, or is radium the only atom that is so rich and bursts with its own richness? This question awaits reply. There is no answer yet at hand.

It is manifest that if a pound of radium emanation starts off naturally with some dozens of megawatts of heat power, and if other substances possess like stocks of power awaiting liberation, it would only require the discovery of some means of effecting atomic instability in cheaper forms of matter to obtain heat supply on our planet long after coal may have become exhausted.

THE FIELD FOR THE ELECTRIC LOCOMOTIVE.

It is always a pleasant and a profitable thing to hear from those who have been long conversant with electrical work in its most practical form, and we are glad, therefore, to present Mr. H. Ward Leonard's discussion of the electric locomotive question. The questions he raises are not those usually considered in electric traction for the reason that as a rule the tendency in electric railway practice has been toward the rapid dispatch of single cars for fast passenger traffic. As we have more than once noted, this procedure while very valuable within bounds encounters certain other limitations that cannot well be escaped. It is well suited to suburban and interurban work, provided that the traffic does not pass a certain critical density and provided that extreme speeds are not attempted. In the former case every large road has been driven to the operation of trains, perhaps with multiple-unit control to secure acceleration; but still, as trains, which can be run at almost the same working headway as single cars and with much greater carrying capacity. In the latter case the operation of single cars has been definitely proved to be vastly uneconomical of power, by the Zossen tests and by many others. In freight haulage single motor cars are out of the question in work on a commercial scale; and success, as Mr. Leonard clearly shows, hinges on the use of very powerful locomotives hauling as large trains as the grades and the adhesion permit. Speed is a secondary consideration and the whole question is one of cutting down labor and economizing in the dead weights. The longer the train unit under these circumstances, the better will be the economic result.

It is certainly a very striking difference between American and English practice that the train loads for freight in the former should be seven times as great as in the latter, while the discrepancy in costs is nearly four to one in favor of the American roads in spite of higher wages. Of course, part of the difference in train weights must be ascribed to the different lengths of haul, and in general to the magnificent distances which characterize American railroading; but the effect on relative costs is none the less striking. A glance at Mr. Leonard's table shows, however, that the weight of the average American freight train has steadily increased, as indeed the known increase in the capacity of the locomotives would of itself show. That the electric locomotive with all its weight active in adhesion can outhaul a steam locomotive is obvious, and we now know well that electric locomotives can be made of very great hauling capacity. But their use has, up to the present time, been practically barred out by the difficulty of delivering adequate power to them at the voltage hitherto usual. The key to success is obviously the use of a high-voltage working conductor, from which power can be more easily drawn, and this in turn is obviously a case for the use of alternating currents. At the present time the boom in alternating-current railway motors is on, and the old prejudice is for the most part broken down, so that the system can at least be assured of a fair trial. Whether the new commutating alternating-current motors can be made to give good results on very large units such as would be necessary in building freight locomotives of great hauling capacity is an undetermined question. A desperate effort will assuredly be made to fit them for this and every other kind of service, and the results must be awaited before trying to pass judgment.

But in any event the plan proposed by Mr. Leonard more than a decade since, and later elaborated by Huber abroad, certainly offers an entirely practicable means of providing locomotives of any desired power operating on a very simple system of working conductors and possessing in the fullest degree the capacity for easy and perfect regulation now enjoyed by direct-current locomotives. The plan undeniably involves some complication in the equipment of the locomotive, but nothing of a forbidding character; and a locomotive thus equipped has the valuable property of being able to run on almost any sort of distributing system that would be used for any kind of railroading. If it should prove of large capacity the composite locomotive could be run perfectly well from the working conductors which served to feed alternating-current locomotives for local service, or could at termini work admirably upon a third rail system if such a thing survives the irruption of alternating currents. It is a system, too, which can very easily be tried on a railroad for the most part equipped with steam locomotives, and certainly it possesses a flexibility which goes far in making up for its complication. As we remarked in commenting on the paper by Huber published some time since, we should very much like to see the trial made on a commercial scale, and given a full and complete test. The complete success of this or any other form of electric locomotive utilizing alternating current in the working conductors, would result in opening the field of general railway traction at once, and the duel between steam and electricity could then be fought out on its merits. Steam locomotives have now worked up to about the limit of size that can be practically used for railway roadbeds, bridges and tunnels as at present arranged, and the double-header is, as Mr. Leonard remarks, not a very good way out of the difficulty. The time is soon coming when electric freight and haulage must be tried to settle the question of its usefulness, and without disparaging the steam locomotive in the least, we feel that it will have a desperate battle to hold its supremacy. The present attitude of the managements of main steam railroad lines toward the adoption of electricity is far more encouraging and determining than electrical engineers have thus far allowed themselves to believe.

Important Developments in European Electrical Industries.

It would appear from recent statements by the *Frankfürter Zeitung* that the Allegemeine Elektricitats Gesellschaft has bought an interest in Brown, Boveri & Co. It is understood that there was paid for 4,500,000 marks of shares of the Brown, Boveri Co., 3,500,000 marks in "A. E. G." shares, representing at the present quotation of about 210 per cent., a cash valuation of the investment of $1,765,000. These are not treasury shares, however, and no corporate action was taken in this connection; but it is simply a deal with the previous owners of the shares, the right being reserved to the other shareholders to participate in the deal in proportion to their holdings. The new "A. E. G." shares will consequently not become the property of the Brown, Boveri & Co., but on the other hand the "A. E. G." will acquire 4,500,000 marks of Brown, Boveri shares. The action was probably prompted by the desire of the "A. E. G.", which now undertakes the manufacture of turbines, to co-operate with Brown, Boveri & Co., who have been successfully engaged in this field for some time. As is well known, Brown, Boveri & Co. are constructing turbines after the Parsons system, while, in addition to its Riedler-Stumpf system, the "A. E. G." recently entered into an arrangement in America with the General Electric Company with regard to the manufacture of Curtis turbines.

The share capital of the Swiss firm of Brown, Boveri, of Baden, amounts to 12,500,000 francs, on which there was distributed in the last three years dividends of 7, 5 and 10 per cent., respectively. For the current fiscal year the prospects of the company are particularly promising, particularly on account of the large new business of the company in turbine construction.

Indirectly, the "A. E. G." acquires through this exchange of shares an interest in the Brown, Boveri Co. in Mannheim and the "Motor" Company for applied electricity in Baden, the "securities owned" (8,040,000 francs) of the Baden Brown, Boveri Co., being largely composed of these shares.

The increase of capital contemplated by the "A. E. G." will now have to be raised by a further 3,500,000 marks above the originally proposed 22,500,000 marks, so that the total share capital will in the future amount to 86,000,000 marks. This would apparently include the new capitalization due to the amalgamation of the Curtis steam turbine patents and the Riedler-Stumpf patents in the United Steam Turbine Company, of Berlin, for the use of these inventions in Germany, Austria-Hungary, Russia, Holland, Belgium, Sweden, Norway, Denmark, Switzerland and the Balkan States. This company, which, it seems, has been jointly formed by the American and German interests, has a capital stock of $750,000, while a separate company for the actual manufacture of the turbines, which will be undertaken in the workshpos of the Union Electricity Company, is on the point of being constituted with a capital of $1,250,000. Another company for Italy is also to be established to work in conjunction with the Mediterranean Thomson-Houston Company.

Single-phase Third-rail Roads for Indiana.

One of the most interesting and important signs of the times is to be noted in the contracts just awarded in Indiana for single-phase, third-rail roads. The first contract is for the equipment of the Fort Wayne, Decatur & Springfield road, extending from Fort Wayne, Ind., to Springfield, Ohio. On this road the Westinghouse single-phase motor equipment, with induction control, has been adopted, as it was not necessary to use existing direct-current trolley lines in any of the cities which are entered. The Indianapolis & Cincinnati Traction Company, which is constructing a high-speed line between Indianapolis and Connersville, Ind., has given out a contract for the equipment of 53 miles of road with the Westinghouse single-phase, alternating-current railway system. This is to be a high-speed line, largely on private right of way, going ultimately to Hamilton, Ohio, and thus making it possible to give high-speed electric service between Indianapolis and Cincinnati. The third-rail system had been practically decided upon before the advent of the single-phase system. The opportunities for saving in first cost and operation by the single-phase induced President C. L. Henry and Sargent & Lundy, consulting engineers for the work, to reconsider their plans for a direct-current third-rail road with rotary converter sub-stations and to adopt the single-phase. Two 500-kw. three-phase, 25-cycle, 2,300-volt generators were contracted for some time ago, to be used in connection with the third-rail direct-current system, with polyphase distribution. The power station equipment, as regards generating machinery, will remain unchanged. The step-up transformers, which will raise the voltage to 16,500 for transmission, will be connected on the Scott system, so as to give two-phase current on the high-tension line. There will be six static transformer sub-stations, one-half of which will be connected on one phase, and the other half on the other phase. The transformers in these sub-stations will give 3,300 volts on their secondary terminals, which will be the trolley line voltage. This voltage will be reduced by a transformer on each car.

In view of the fact that all cars must operate over the 500-volt direct-current city lines in Indianapolis, rheostatic control will be used instead of the induction control, which would be used were it not necessary to operate over direct-current trolley lines. Both methods of control might be used on a car, but the weight and complication of having two methods on a car are thought to offset the small economy gained by the induction control on the alternating-current portions of the line. One of the chief advantages of the induction control is its economy in starting a car. On the interurban portion of the line, however, the stops will be few, and hence, if induction control were used it would have to be put on simply to gain economy in a comparatively small number of stops. The first contract calls for ten cars, each equipped with four 75-hp motors, with gearing which will give a maximum speed on a level of 42 miles per hour. These cars are intended for local service.

The sub-stations will be approximately 10 miles apart. The trolley wire will be No. 000 copper. There will be no feeders supplementary to the trolley wire. The sub-station transformers will supply 3,300 volts direct to the trolley line.

The consulting engineers estimate that in the equipment of the entire ultimate road of 93 miles from Indianapolis to Hamilton a saving over the former direct-current plans of $500,000 will be effected in first cost. The adoption of this new system involves also little apparatus which would have to be discarded in case the single-phase alternating-current system did not prove to be a success. The generators at the power station, the transmission lines and the motor equipments would all serve equally as well on a 500-volt direct-current system, with high-tension transmission, and to change to such a system with rotary converter sub-stations would necessitate only additional direct-current feeder copper and the installation of rotary converters and step-down transformers at the sub-stations.

Merger of Chicago Electrical Association and Western Society of Engineers.

On the evening of February 19 forty-one members of the Chicago Electrical Association dined at the Albion Café, it having been previously announced that the question of merging the Chicago Electrical Association into the Western Society of Engineers would be fully discussed and voted upon at that meeting. The Western Society of Engineers is an organization maintaining permanent headquarters in the shape of library, reading-rooms and meeting-room, with secretary's office in Chicago. It is composed of all classes of engineers, being in the nature of a general engineering society, with a membership on January 1, 1904, of about 700. According to the plan proposed and agreed upon, members of the Chicago Electrical Association will be admitted to the Western Society of Engineers without the payment of initiation fees. Members of the Chicago Electrical Association will constitute the electrical section of the Western Society of Engineers. The president of the Chicago Electrical Association will become a vice-president of the Western Society of Engineers and will be chairman of the electrical section. The work of the electrical section will be conducted as the association work has been heretofore. The advantages of the plan are that there are a number of men who would be desirable members for both associations, but who would not care to take the burden of joining two different organizations. The electrical association heretofore rented the use of the meeting-room of the Western Society of Engineers. It will now have a home of its own and will secure the benefit of the publication of its proceedings in the *Journal* of the Western Society of Engineers, and also the advantages of the library, reading-room and permanent secretary's office maintained by the Western Society. At the dinner some regret was expressed at the giving up of the name of the Chicago Electrical Association, which has become so well known, but it was the general sentiment that the advantages to be gained by consolidation would more than offset some of the disadvantages.

The Seattle Municipal Light and Power Plant.

By R. E. HEINE.

THE city of Seattle (population 140,000) is at present planning and erecting an electric power plant and transmission system for the purpose of supplying the city with electric light and power. The electric current generated is to be used, first, for street lighting, operating series incandescent and arc lamps, and later on for the operation of alternating-current motors and ordinary incandescent lights. No direct-current distribution is being planned for at present. The system at present includes a generating station near Cedar Lake, about 40 miles southeasterly from Seattle, two three-phase transmission lines and a distributing station at Seattle.

Power will be generated at 2,300 volts, 60 cycles, three-phase. This source of Seattle's water supply, which is carried to the city partly by the Cedar River and partly by a 48-in. wooden stave pipe. The idea of locating a municipal power station at this lake originated with the present city engineer, Mr. R. H. Thomson. The city owns the river for water supply and a greater part of the pipe line, which the transmission line will follow for 28 miles.

About one-half mile below the lake a substantial timber dam has been constructed, and from this a 49-in. wooden stave pipe joined further on to a steel pipe carries the water to a point three and one-half miles below to the site of the present power house. The gross head of water is 610 ft., and the effective head at the turbines is 560 ft. The wooden stave pipe is of fir, $1\frac{5}{8}$ in. thick and has a total length of 15,729 ft. The riveted steel pipe is 48 in. in diameter, the plates are 3/16 in. thick at the upper end and 9/16 in. thick at the power house. The stave pipe is being made at the city's saw mill

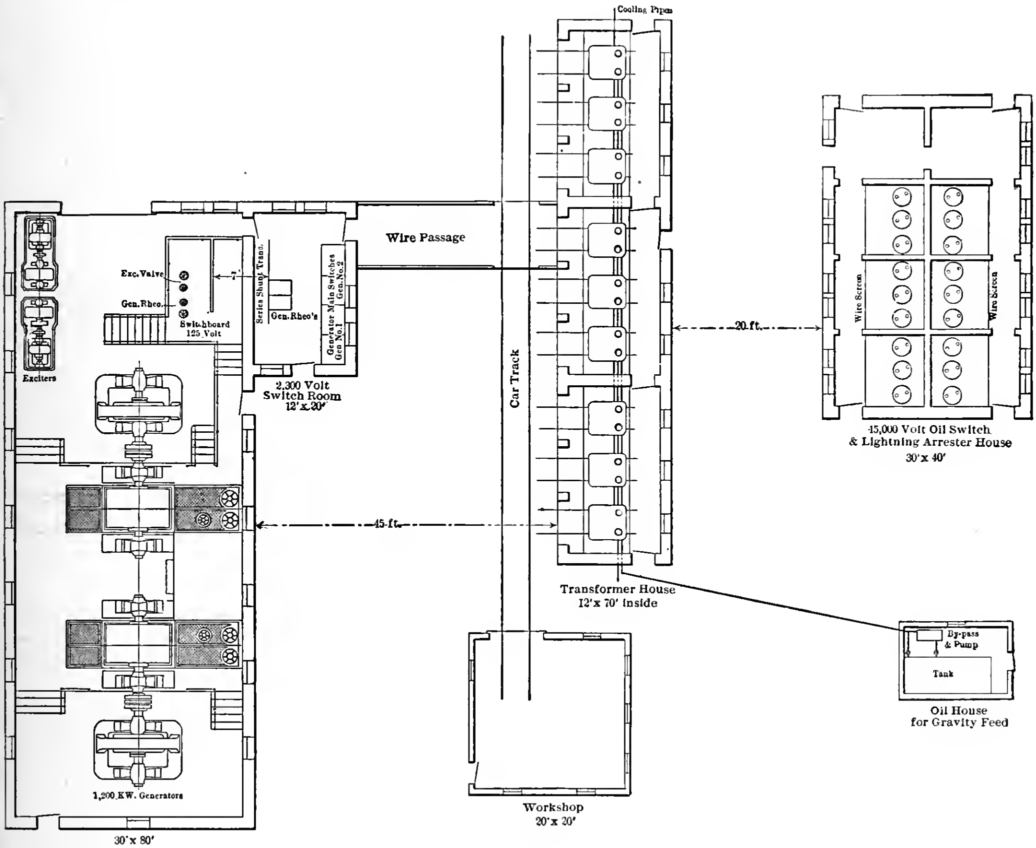

FIG. 1.—GROUND PLAN OF SEATTLE GENERATOR STATION AND MAIN BUILDINGS.

will be stepped up to 44,000 volts and transmitted to Seattle over two three-phase lines. At Seattle the current will be stepped down to 2,200 volts and changed to two-phase.

At the present time the lights and motors in Seattle are operated by two companies, both using a 60-cycle, two-phase system; furthermore, all of the load for the first few years will consist of arc and incandescent lights only. Hence, it was decided to adopt the rather high frequency of 60 cycles per second, and permit a switching of the load from one station to another in case of accident. The distributing station in Seattle will be provided with synchronizing devices, which allow for the supplying of power for the principal circuits during a shut-down of any one plant through accident or otherwise.

The source of water supply, Cedar Lake, is a clear body of water about three and one-half square miles in area situated in the lower Cascade Mountains, 1,535 ft. above sea level. The lake is also the at Cedar Lake and the steel pipe was furnished by the T. A. Gillespie Company, of Pittsburg.

The total available amount of power is 30,000 hp, but at present but 5,000 hp will be developed. In order to utilize the total power additional storage reservoirs are required.

Two Pelton water wheels, of the two-wheel type, will furnish power to the generators. The wheels are direct-connected to the generators, and operate at 400 r.p.m. They are capable of developing 50 per cent. overload and are guaranteed to operate at a minimum efficiency of 80 per cent. at full load. A Lombard governor controls each wheel. Two 125-hp wheels, running at 525 r.p.m., furnish power for the exciters, and are controlled by one Lombard governor.

The generators are standard machines of the Bullock Electric Company, of 1,200 kw output, 2,300 volts, 60 cycles, three-phase, of the revolving field type. The guaranteed efficiency of the generators is 95 per cent. at full load and the regulation is 8 per cent. on non-inductive load, 16 per cent. for a power factor of .9 and 20 per cent. for a power factor of .9, speed and excitation remaining constant. Two generators will be installed at present, but the plant is so arranged that additions may be made without interrupting the service.

The exciters are in duplicate, and of 75-kw capacity, 125 volts, compound-wound. Either exciter is capable of furnishing current for both generators for the lights in the station and for operating the motors in the station. This arrangement keeps one exciter in reserve for emergency service. Fig. 1 shows a ground plan of the station and the surrounding buildings and Fig. 2 gives sectional elevations of the same.

The switchboard at the generating station is placed on an elevated platform at one end of the present building, overlooking the machines. When the entire plant will have been erected it will occupy a central position. The board is made of Vermont marble, and is but 8 ft. long and 90 in. high, containing but four panels, two for the generators and two for the exciters. There are no alternating-current bus-bars and consequently there is no need for any transformer panels. A space of 4 ft. is left between the wall and the board, and all instrument and pilot wires pass down the back of the board, underneath the floor and through a wall to an annex 12 ft. x 20 ft. Here are kept all the switchboard transformers, shunts, exciter and generator rheostats and the electrically-operated oil switches.

The exciter rheostats are controlled by means of a chain and sprocket wheel from the panel, and the generator rheostats from pedestals with hand wheels in front of the panel. This gives an arrangement absolutely clearing the board of all dangerous voltages, and at the same time minimizing the amount of wiring to the panels.

The transformer house is of stone, 70 ft. long and 12 ft. wide on the inside. It is divided into three fire-proof compartments, each containing one bank of three transformers, which are all placed in a single row. A path 4 ft. wide is left the entire length of the house for the attendant; the oil and water taps, oil gauge and water overflow and thermometer are placed along one side of this path, so that observations can readily be made. A concrete pit runs the entire length of the building below the transformers, and in this are carried the oil and water pipes. A large tile opens from this pit below each transformer to drain burning oil in case of fire.

The high-tension leads leave the building through large tiles and are supplied with glass tubes supported by the wire. The glass tubes extend several inches beyond each end of the tiles. There are no high-tension switches in the transformer house. A pilot switch, however, is provided for each bank, so that in case of fire or accident the bank may instantly be cleared on both the high and low-tension side. The electrically-operated switches adapt themselves to this arrangement without adding any complications. Each transformer is mounted on a car resting on a truck by which it can be run into the shop for repairs.

At the same time that it is ideal to have all parts of a generating plant in sight at all times, experience has proven that this may result in the loss of the entire plant. The rapidity with which burning oil spreads and its intense heat, combined with the fact that water merely spreads it, makes it almost uncontrollable when once started. Being "between the devil and the deep sea," it was decided to first reduce the risk of fire and then make everything as convenient as possible under the circumstances. To this end a separate high-tension switching and lightning arrester house was designed. This building is constructed of stone and concrete, 40 ft. x 30 ft. wide. It

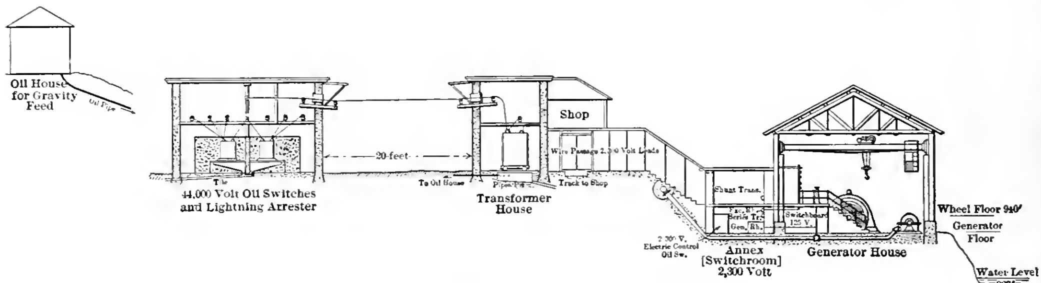

Fig. 2.—Cross-Section of Elevation Generating Station and Main Buildings.

The exciter wheel pipes run directly under the switchboard platform; valves are connected in here and pedestals for their control are placed on each side of the rheostat pedestals.

A motor control on the Lombard governor, operated from the board, places the main water wheels under control from the board. All parts of the plant are, therefore, under direct control of the attendant at the small 8-ft. switchboard, and any operation may be performed almost within arm's reach.

Inasmuch as both generators are of the same capacity as the bank of transformers which it supplies, there is no necessity of interchanging the generators, and bus-bars are not required. Each generator is provided with two main switches, one of which connects it with its own bank of transformers and the other connects it with a spare bank during changes or repairs.

The three ammeters on each generator panel are of the vertical edgewise type, and any unbalancing of any one phase throws that pointer out of the line and makes it more conspicuous. The generator panels contain the usual equipment of line ammeters, field ammeter, switch indicating wattmeter, Lombard governor control button, and pilot switches to control main switches. The integrating wattmeters are not placed on the board, not being necessary for operation. All switchboard instruments are finished in black and polished copper. The exciter panels are of standard pattern, and are equipped with Weston instruments.

From the generator house a passageway carries the leads to the transformer house, which contains nine transformers, each of 400-kw capacity, 60 cycles, 2,300 to 45,000 volts, of the oil-insulated, water-cooled type. These are built by the Stanley Electric Company, of Pittsfield, Mass.

is divided into eight compartments by concrete walls rising to such a height from the ground as to leave room for the two sets of bus-bars connected to the high-tension lines.

In six of these compartments are placed the six triple-pole, 45,000-volt oil switches. Each of these switches is provided with a disconnecting switch to clear the oil switch from the line during repairs. There are no single-pole switches used on the high or low-tension lines. This helps to prevent the unbalancing of the lines, and as one bank of transformers is held in reserve there will be no need of using two transformers in delta connection at any time.

The end compartments carry two sets of lightning arresters (one set for each transmission line) with their disconnecting switches, and from here the lines go out to Seattle. Fig. 3 shows a complete diagram of connections and wiring at the generating station.

The oil is fed to the transformers by gravity from a tank in the oil house, situated on a hill nearby. The oil can be returned if necessary through the same pipe by means of a by-pass and pump.

The lines will be built of cedar poles, 35 to 40 ft. in length, spaced approximately 140 ft. apart. There will be two lines, each carrying one circuit consisting of three No. 2 B. & S. medium hard-drawn copper wires spaced 72 in. between centers in the form of the usual triangle.

As no railway work is contemplated, the two lines will probably be operated in multiple and be so arranged that either one can be quickly disconnected should a short-circuit or ground occur on the line. Much of the country through which the lines pass is covered with fir trees up to 250 ft. in height and damage caused by falling branches will probably make this plan an advisable one. The entire plant, however, is in duplicate and can, therefore, carry separate lighting and motor loads.

One of the lines carries a telephone line of two No. 11 B. & S. hard-drawn copper wires on a 5-ft. cross arm 5 ft. below the cross arms of the power circuit. The transmission lines will be transposed in opposite direction every two and one-half miles, and the telephone line at shorter intervals. The wire for the lines and interior work has been furnished by the Standard Underground Cable Company, of New York.

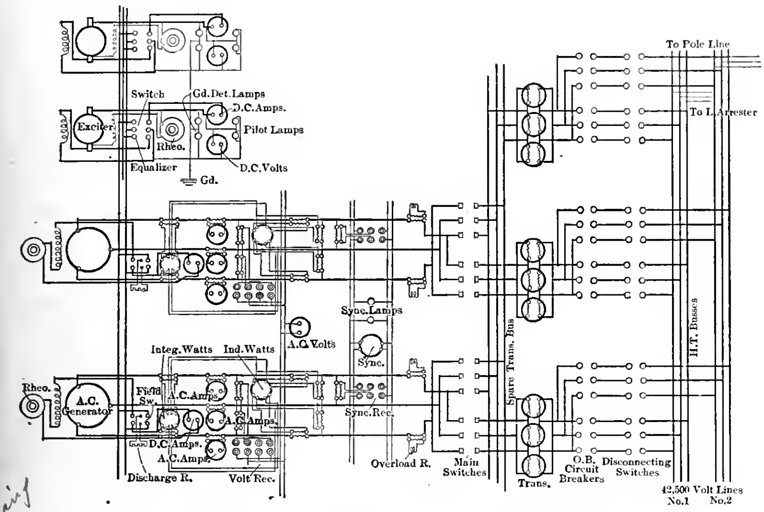

Fig. 3.—Wiring Diagram of Generator Station Main Circuits.

The insulators for the greater part of the system are supplied by the California Electric Company, of San Francisco. They are of the three-part porcelain type, weighing 11½ pounds each. They are 10 in. in diameter and 11 in. high over all.

The sub-station (corner Yesler and Seventh Avenue) will be a fire-proof structure of brick and stone. The high-tension wires will enter on the side of the building and the oil switches, all triple-pole, will be in separate compartments. The transformers are of 600-kw capacity each, in banks of two, changing from three-phase to two-phase at 2,200 volts for distribution. Concrete barriers separate the transformers and a pit with tile drains is arranged below them as in the case of the generating station. A car truck for moving the transformers is also supplied. The transformers are of the water-cooled type, the cooling water being supplied from the city water mains.

The sub-station switchboard, like that in the generating station, is a 125-volt board. The 2,200-volt switches and regulators are placed immediately below the board and are controlled by handles and hand wheels at the board. Only plain 125-volt wiring is on the board, and the panels are polished on the back as well as on the front. From the switches the circuits are run to the "tub" transformers for series arc street lighting and to the overhead and underground systems for other purposes. Fig. 4 shows a complete diagram of connections for the sub-station.

The switchboard is of Vermont marble. One panel is provided for each bank of transformers and carries an ammeter for each phase, a voltmeter receptacle, two levers for operating the four-pole oil switches connecting to either of two sets of bus-bars, and two levers operating the two triple-pole, high-tension oil switches to throw the transformers on either line. As there are no double-throw switches throughout the plant, the load can be transferred without dropping it during transfer.

A somewhat similar panel is provided to tie in with another station in case of line trouble or a shut-down of the plant. This arrangement provides for a transfer to or from the sub-station of 2,000 hp at 2,200 volts. This panel carries, besides the voltmeter, ammeters and oil switch levers, a frequency indicator, which may be connected to either system.

The distributing panels are single-phase, every alternate one being of the same phase. Each carries an ammeter and voltmeter receptacle together with two double-pole oil switches with overload relays by which the load may be transferred from one set of bus-bars to another of the same phase on the other side. Wattmeters are supplied for all of the panels, but are not placed on the board. Emergency switches are provided for on poles near the building by which the entire load may be cut off the building at the receiving station in case of fire or accident.

The entire design and construction of the plant is under the supervision of Mr. R. H. Thomson, the city engineer of Seattle, who has also constructed for the city its present water works system, one of the most successful in the West.

The designing and planning of the electrical work of the plant has been done by Mr. J. D. Ross, electrical engineer of the city, who is in charge of this part of the work.

U. S. Army Wireless Telegraphy.

After experiments for six months the success hoped for was attained over the United States Army wireless telegraph line between Fort Wright, Fisher's Island, and Fort Schuyler, N. Y., a distance of 97 miles. Messages of 1,000 words each were exchanged and read as distinctly as an operator could read a land line, at a speed of 30 words a minute. The line established is intended for use between St. Michaels and Nome, Alaska, where it has been impossible to establish ground lines because during the winter the cables are wrenched away by the ice. Upward of $350,000 has been expended to establish a land telegraph line, but without success.

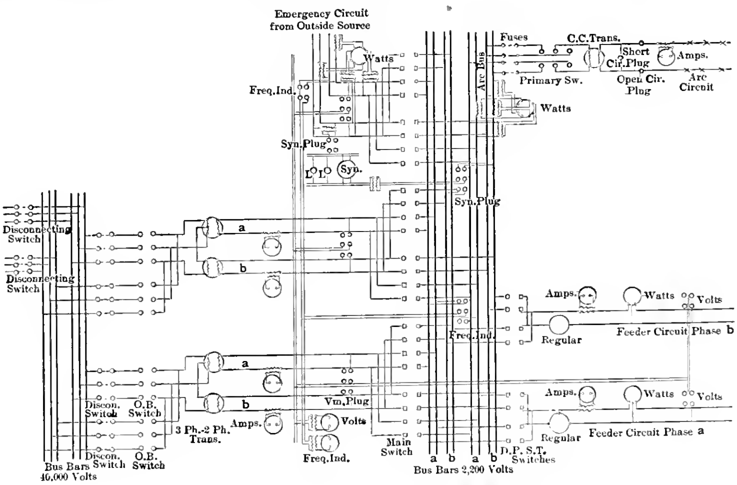

Fig. 4.—Wiring Diagram of Sub-Station Main Circuits.

How Can We Haul by Electric Locomotives Freight Trains Weighing Twice as Much as Those Now Hauled by Steam Locomotives?

By H. Ward Leonard.

FOR many years past the most important problem before the electrical engineers of the world has been the development of an electric locomotive which would commercially replace existing steam locomotives. It is a fact, the significance of which is apparently not appreciated, that the cost of hauling freight is inversely proportionate to the number of tons handled in a single train. For many years I have firmly believed that the principal advantage possessed by electric power when compared with steam power for tractive purposes lies in the possibility of hauling by means of electric power upon existing railways, freight trains very much heavier than can be hauled by steam locomotives. The way to make the maximum net earnings out of a trunk line railway is to keep in every block section a freight train of the maximum possible weight and moving at as high a speed as practicable; for this means that the enormous fixed charges of a railway are distributed over the maximum possible tons of freight and hence the fixed charges per ton mile are reduced to a minimum. In support of these ideas, I have prepared a table, printed herewith, showing the enormous economies which have been made in this country since 1894, principally due to the great increase in the draw-bar pull of the locomotives.

I also give a tabulation below, from which it appears that the average train load in tons on the Pennsylvania Railroad was about seven times as much as the average load in tons for the London and N. W. Railway, these figures being 518 and 72 respectively; while the cost per ton-mile for the Pennsylvania Railroad was only about one-quarter of the cost per ton-mile of the London and N. W. Railway, these figures being .4 and 1.49 respectively.

UNITED STATES STEAM RAILROADS.

	1901.	1900.	1899.	1898.	1897.	1896.	1895.	1894.
Total number of locomotives (including passenger locomotives)	39,729	38,065	37,245	36,746	36,410	36,338	36,610	36,304

It is a well-known fact to those who have given consideration to such matters that the steam locomotive on account of various limitations cannot be made much more powerful than it now is. It is also well known that the most powerful steam locomotives have such extraordinarily high depreciation as to make it very doubtful whether any real economy has been gained by the most recent increases in size and power.

The urgent demand for greater hauling power leads frequently to double heading; that is, the use of two steam locomotives on one train. Each of these steam locomotives can develop, say, 175 hp, but double heading is not nearly so economical, for many reasons, as would be the case with one large locomotive or two locomotives which would perfectly divide the total load between them and which would be, at all times, under simple control by one operator.

When judging the comparative advantages of the various electric systems which have been proposed for railway work, it seems to me that all other considerations must be secondary to the consideration of whether the system has the ability to haul greatly increased train loads over long distance with a maximum of reliability and a minimum of depreciation and with a system of control which will give the minimum investment in power plant and transmission system. I believe that the Ward Leonard system possesses these desirable qualities to a higher degree than any other system yet proposed, and that by means of large locomotives operated upon this system, very great economies can be effected in the cost of hauling freight upon existing trunk line railways, as compared with the best results obtainable by the present steam locomotives.

Time alone can show what the best form of electric locomotives will be for hauling the enormous freight trains, which I think we shall see in the not distant future; but I am convinced that extremely powerful electric locomotives will soon demonstrate their superiority over steam locomotives for long distance freight haulage, and when this fact is conclusively demonstrated, there will follow an industrial revolution, the extent of which seems almost unlimited, and, in comparison with which the electrical work we have thus far seen will appear utterly insignificant.

Removal of Car Tracks.

One of the recent bills introduced in the New York Legislature allows a company to remove its unused rails without impairing its franchise, and to relocate its route with the consent of local authorities so as to meet changing conditions of traffic. At the present time there are said to be a number of miles of street occupied by street railroad tracks laid under valid franchises, upon which the street railroad companies are compelled in self-protection to operate a few cars in order to keep the franchises alive for use in case they should hereafter become important. It is declared to be to the city's interest that the company should be free, with the consent of the city, to remove such tracks in order that the condition of the street may be improved. The fourth bill would allow the removal of such tracks without invalidating the franchises. In New York City, for example, on Amsterdam Avenue there are four tracks, two owned by one company and two by another. One company is said to be quite willing to discontinue the use of its track and use the tracks of the other company, but has been unable to do so, because of the objection of the trustee of its mortgage that if the tracks were removed the franchise would be imperiled.

New York Subway Model.

In the rooms of the Rapid Transit Commission in New York City there is on exhibition an elaborate model of the great work, that is to be shown at the St. Louis Fair. On a massive carved oak table is a miniature New York underground railroad station, brilliant with small electric bulbs. Looking through this the spectator will get a view back into a section of tunnel, equipped with tracks, signal appliances and lights, and with tiny electric trains at intervals. A brass plate on the front of the table explains that this is the New York subway designed by Mr. William Barclay Parsons, chief engineer. In a big showcase, on another oak table, will be exhibited various minerals and curios found below the surface of the city by the subway builders, including cannon balls dug up in Elm Street, ancient coins found all along the line, and even a human skeleton.

A Composite Plant at Bloomsburg, Pa.

By L. S. Levy.

Of the numerous small water powers in the eastern part of Pennsylvania, one that has been utilized to good advantage is that on Fishing Creek, a tributary of the Susquehanna River, flowing into the latter at Bloomsburg. It is on the banks of this creek that the old Irondale Iron Company had its mills. The skeleton of the pig-casting house is still standing; it was almost entirely of wood, as were the two jib cranes that served the casting floor. These cranes, in their bare simplicity, are silent witnesses of the methods of fifty years ago. The old blast house is now occupied by the plant that forms the subject of this notice. The blowing engines were driven by two overshot wheels located in the very pit in which their more modern successors have been installed.

The Irondale Electric Light, Heat & Power Company was incorporated on April 7, 1902, with a capital of $50,000. This company was organized for the purpose of using the Fishing Creek Falls for electric power generation, the existing service being inadequate. The falls are situated about two miles from the center of the town, and about one and a quarter miles above the power house. The old dam at this point was repaired and raised to a height of 15 ft. The im-

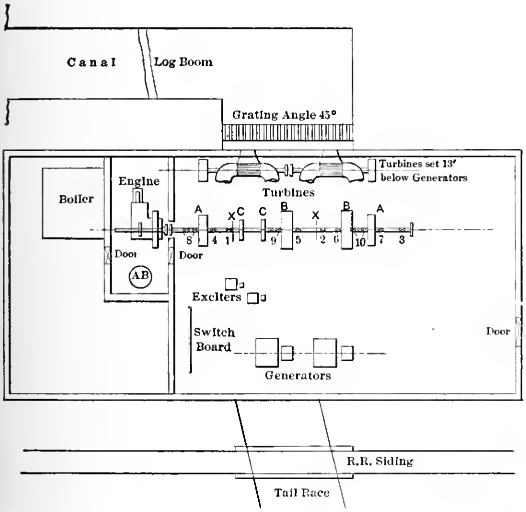

FIG. 1.—PLAN OF STATION.

pounded water is conveyed to the power house by means of the old canal, as the latter required very little repair to put it into good shape.

The power house is a building 108 ft. x 40 ft., and is two stories in height. Only the ground floor is used for power purposes, the object being to rent the upper floor for factory purposes. Reference to the plan diagram in Fig. 1 will show the location of the turbines. There are two horizontal wheels 30 in. in diameter of the Victor type, which operate under a head of 29 ft., and develop 250 hp at a speed of 250 r.p.m. Regulation is effected by means of a Snow governor, which serves both turbines through a countershaft. Power is delivered to the main shaft through Candee 10-ply canvas belts.

As an auxiliary in times of low water, ice jams, etc., a 300-hp engine is installed. This was built by Russell & Co., Massillon, Ohio. It is of the simple automatic type, cylinder 19 in. x 22 in., speed 200 r.p.m. When required for service it is direct-connected to the main shaft through a flange coupling. Steam is furnished at a pressure of 100 pounds by a 300-hp water tube boiler built by E. Keeler & Co., Williamsport, Pa., who also furnished all steam auxiliaries, including a Scranton boiler, feed pump, Hancock inspirator, Burrows damper regulator, etc.

Conditions that had to be met in this station practically dictated the use of a quill shaft. It had to be possible, of course, to operate either generator, or both, from either turbine, or both. These conditions are very handily met, as will be readily understood by reference to Fig. 1. This will give an idea of the layout of the station in addition to the shaft itself. The turbine belts run over pulleys A and A'. These pulleys are mounted on quills 5 ft. 9 in. long and $7\frac{5}{8}$ in. and $6\frac{5}{8}$ in. in diameter. One portion of a 40-in. Hill clutch is mounted on a quill, the other portion of the clutch being, of course, mounted on the inner shaft. Each of the generator pulleys B and B', is 90 in. in diameter, with a 27-in. face, and is mounted on a quill. As

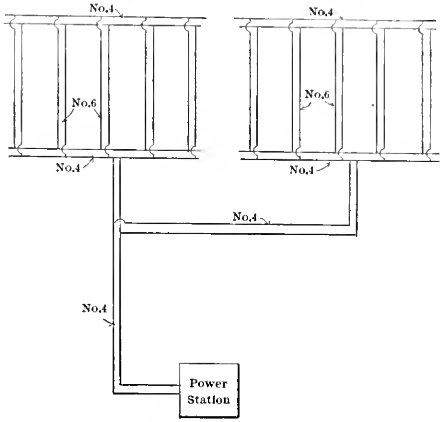

FIG. 2.—DIAGRAM OF DISTRIBUTING SYSTEM.

with the turbine quills, they are connected with the main shaft by clutch couplings. At C and C' are shown the exciter driving pulleys. The pedestal bearings 1, 2 and 3 serve the inner shaft alone: 4, 5 and 6 serve the quill alone, 8 and 9 are double bearings, serving both quill and inner shaft, while 10 has three journals, the outer two serving quills and the center one the inner shaft. At X the inner shaft is divided, the parts being connected with flange couplings. This arrangement has worked very well, and when additions are made to the plant they will be installed in a similar manner.

The generators are Westinghouse two-phase machines of the revolving armature type. They are driven at 514 r.p.m. and furnish current at 2,200 volts and 60 cycles. They are rated at 180 kw, and are guaranteed to stand 25 per cent. continuous overload, with no greater increase in temperature than 40° C. They are excited by two $3\frac{3}{4}$-kw, four-pole generators, either one of which is sufficient for both of the large machines. The main generators have a compound field, but the series winding is used only when the machines are operated in multiple.

The current is carried to the switchboard by wires laid in ducts under the floor. The switchboard comprises three panels—two gen-

FIG. 3.—INTERIOR OF STATION.

erator and one feeder. On each of the generator panels is mounted two ammeters; a recording wattmeter, double-break main switch rheostats, etc. There will be seen on the small framework at the left of the switchboard four instruments; the upper two are voltmeters, while the lower left is a frequency meter, and the lower right one is a synchronoscope. At the bottom of each of the generator panels are three plug receptacles that are used for making equalizing connections between the exciters, and for serving the same purpose for the series winding of the main generators when they are operated parallel.

The distributing system has been carefully worked out along the following plan: Four No. 4 copper wires are carried to the center of distribution, which is at a distance of 3,000 ft. from the station; at that point they branch off, as shown, and are carried for about 500 ft. on the company's own poles. For the remaining 2,500 to the center of distribution the wires are carried on the Bell Telephone Company's poles. Any trouble from induction is avoided by two transpositions. The poles are spaced 120 ft. apart, and on every fifth one a lightning arrester is mounted. Both branches of the circuit running up and down the main street are No. 4; the crosstown lines are No. 6. It will be noted that there is plenty of copper, but the excellent service rendered has well justified the outlay. Customers are well satisfied, and there is no reason why they should

FIG. 4.—CANAL.

not be, for there is very little difference in voltage between one end of the town and the other.

At the present time there are 3,500 lamps connected and there are about 120 being added every week. There is a load of about 50 hp in small motors, and this business is also increasing on account of the cheap rates and the good service rendered. Many establishments in town are using water motors, and these are being rapidly replaced with two-phase induction motors; $30 per horse-power per year is charged for motors, while the lighting rate is still on a flat basis of 30 cents per lamp per month. The plant was installed and is operated under the supervision of Mr. William O. De Witt, a student of the International Correspondence Schools, of Scranton, Pa., and manager of the company. It is due to his courtesy that the writer has been enabled to inspect the plant and gather the particulars given.

British Westinghouse Electric Affairs.

At the fourth annual general meeting of the stockholders of the British Westinghouse Electric & Manufacturing Company, Limited, held in London February 5, Mr. George Westinghouse, the chairman of the company, made some very interesting statements. He said in part: "The orders in hand not executed on January 31, 1904, amount to £1,608,256, the patterns, new tools and special machinery required in the execution of these orders and the large amount of labor involved before any shipments of complete apparatus can be made, require working capital in proportion, and as I said at the last annual meeting in reference to the proposed authorization of 200,000 new preference shares, this additional working capital which your extensive plans have contemplated from the first, is fortunately needed sooner than some of us expected. I may say 'fortunately,' because we have already secured such a volume of business as to justify the profitable use of the additional working capital, which will be required to carry the materials and accounts involved in the execution of existing contracts. Your works at Manchester at present give employment to about 7,000 operatives and the buildings have been so planned that extensions can be made for a comparatively small expenditure of capital, which will generally increase their output. In Australia and New Zealand business generally has greatly improved and our sales show a satisfactory increase during the year under review. Our representatives (Noyes Brothers) have just informed us that owing to developments they have thought it necessary to establish a separate branch office in Western Australia. In South Africa there has been a marked revival in our business during the past year and we have recently arranged for more active representation for extending our connections there, in view of the probable great demand for electrical apparatus for the mines directly the labor difficulty is solved. In India we have made definite arrangements for representation and have recently secured an order for an extensive power installation, besides a considerable amount of apparatus for the mining district. We believe that there is likely to be an increasingly active demand for electrical apparatus from the British colonies all over the world. It must also be remembered that not only do we manufacture for the home trade and the colonies, but under the terms of the agreement in relation thereto we have furnished apparatus for several large orders for the execution of contracts in the territory of other Westinghouse companies, notably on the continent of Europe and in South America, and there are now pending a number of important negotiations. The importance of this relation between the various Westinghouse companies may be illustrated by a quotation from a report just made to me from the manager of the French Westinghouse Company:

"'We have the great advantage of the assistance of the various Westinghouse companies, the value of which it would be difficult to commute; our ability to obtain by cable, at short notice, estimates and specifications of new material to meet new conditions, as evidenced recently by information supplied us concerning single-phase apparatus, places our company in the front rank of continental manufacturing concerns.'

"From the beginning of your operations it has been apparent to your directors that there should be a head or chief executive for your company. Men of the required experience and personal characteristics capable of managing a property and business such as yours are difficult to find. To the selection of a competent chief executive official I have devoted much thought and investigation, and I have the honor of proposing the election, as one of your directors, of Mr. William I. Buchanan, and to your directors I shall propose his election as deputy chairman and managing director of the company. (Mr. Buchanan's appointment was forecasted in the ELECTRICAL WORLD AND ENGINEER several weeks ago.) Mr. Buchanan, who will, with myself, represent the American companies' interests in the British company, has had an exceptional experience in the management of important affairs and I am satisfied that your business will have that constant supervision and direction which are so essential to complete success. A supervision which it will be impossible for me to continue to give to that extent as heretofore, in view of my larger interests in America, though I propose to still give as much time as possible to the further development of your business. The American Westinghouse companies, in return for ordinary shares, which will not receive any dividend until after the preference shares have first had a dividend of 6 per cent., have already rendered a service or given value in excess of the par value of these ordinary shares. They have, with other American friends, already paid about 30 per cent. of the outstanding preference shares and I am now authorized by the Westinghouse Electric & Manufacturing Company to take as many of 100,000 new preference shares at par as may not be taken by the other shareholders."

All the resolutions put to the meeting were carried unanimously.

Muscular N-Rays.

According to advices which were recently received from Paris, Blondlot N-rays have been proved by Professor Charpentier, of Nancy, to emanate from the human body, and more especially from the muscles. To show this, the Professor suggests a little experiment which can be tried by anyone. It is only necessary to take a piece of black paper, part of which has been covered with phosphorescent sulphur, and place it against a muscle in a dark room. The phosphorescence will at once be seen to increase, and the tenser the muscle the greater will be the effect of the "N-rays." The same effect can be caused with any tense body, such as a bent bow, but what the nature of the rays, or emanations, is the Professor has not yet been able to demonstrate.

Service Power Plant of the Louisiana Purchase Exposition.

IN the marvelous development which characterizes the modern exposition, the supply of electricity for lighting the grounds and buildings and for general exhibit purposes, becomes an important consideration. At Buffalo unlimited power was fortunately available by transmission from Niagara, but at St. Louis it has been necessary to construct a service plant which will primarily be depended upon for furnishing a continuous supply of power to the Exposition; the plant thus resembling in the character of service rendered, the ordinary central station.

Other sources of power will, of course, be necessary, as much more power is required than can be supplied by the service plant. Part of this extra power will be supplied by the various exhibit plants and the remainder from the city system of the Union Electric Light and Power Co. It is contemplated that the service plant and the city plant will operate in parallel during periods when both systems are doing the same work. As the intervening distance is considerably over five miles, this will form an interesting feature of the Exposition service.

The character of the service for which the Exposition plant was built includes general arc and incandescent lighting of grounds and buildings; power for operating 2000-hp direct-connected induction motor turbine pumps supplying the cascades with water, and power for general exhibit work. The distribution is at moderately high potential—6,600 volts—and the frequency now universal in extensive power systems—25 cycles per second—is employed. A high-tension underground conduit system connects the service plant with distributing sub-stations located in the various buildings, where current will be stepped down to alternating-current voltages suitable for general distribution, and converted to direct current for motor work. Miscellaneous voltages and frequencies will be supplied entirely by exhibit apparatus.

The design and construction of the service plant has been carried out by Westinghouse, Church, Kerr & Co., the general contract for the entire equipment being awarded to the Westinghouse Electric and Mfg. Co., Pittsburg, Pa. This company has furnished the entire electrical equipment with the exception of two generators, which are to be supplied by the General Electric Company. The entire engine equipment was furnished by the Westinghouse Machine Company. In thus entrusting the execution of this important work to a single engineering concern, it has been possible, through the close co-ordination of interests involved, to secure the most harmonious and appropriate design consistent with the essentially temporary character of the undertaking and the necessity of conforming to a rigid time limit.

The service plant has not been laid out on elaborate lines with a view to combining the diverse characteristics of an exhibit and a service plant. On the contrary, the construction has been simplified as much as possible in order to reduce complication and to provide the greatest reliability and ease of operation. Standard apparatus has been employed throughout, and particular care has been taken to obviate interruptions of service by duplicating the equipment of vital points. The plant is, therefore, an exhibit plant in so far as it is representative of thoroughly modern practice at minimum cost.

LOCATION.

The space reserved for the service plant is located in the western end of the Machinery Building and in the adjoining Steam and Fuels Building; the former containing the electric generating plant and the latter the steam generating plant. The Steam and Fuels Building also contains miscellaneous exhibits of steam boilers, briquette making and gas-producing apparatus.

The location of the electric plant is conspicuous, as it occupies the central aisle of the Machinery Building, about 230 feet of this aisle being reserved for the plant. This space lies midway between the exhibits of the two largest American electrical manufacturing companies, the Westinghouse Electric and Mfg. Co.'s exhibit occupying the southern wing and the General Electric Company's the northern wing of the building. Each company is represented in the generating and switchboard equipment, and the plant is therefore representative.

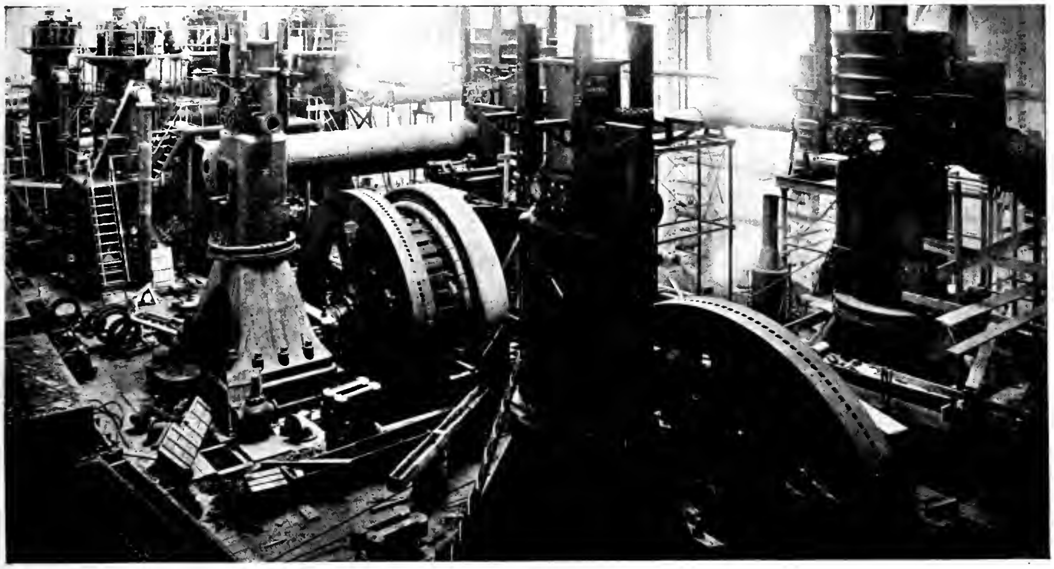

FIG. 1.—GENERAL VIEW OF GENERATING PLANT, ST. LOUIS EXPOSITION.

The main aisle is served throughout its length by several cranes, the runways for which are separate from the building columns. One of these, a 40-ton 3-motor crane, forms part of the plant equipment and was used in its erection.

In the erection of the plant many difficulties were experienced on account of the treacherous nature of the soil, which is made ground on river bottom. All ground had to be piled, not only under the building and machinery foundations, but also under boiler and flue walls, pipe tunnels and overflow conduits.

The buildings, being of temporary character, are naturally of light construction, which introduced further difficulties in providing proper supports for piping. It was found necessary to support the large piping directly from the floor upon steel towers.

The general arrangement of the steam and electric plant is shown in Fig. 2.

GENERATING PLANT.

The main generating plant is of 8,000-kw capacity, in four units of equal size. The plant is served by three 80-kw exciter units, two of which are sufficient to operate the entire plant together with such auxiliary machinery as may be required in the adjacent exhibits, leaving the third unit as a reserve.

Each pair of generating units receives steam from a separate steam line, in turn supplied by a separate battery of boilers, and exhausts into a separate condenser. The entire plant thus consists of two sections practically in duplicate, which may be operated independently or together.

Each generating unit consists of a Westinghouse-Corliss vertical cross-compound engine direct-connected to a 2,000-kw revolving field alternator, the unit operating at 83 r.p.m. The engine is 38 x 76 x 54, indicating 2,883 hp at full load with 27½ pounds mean effective pressure referred to the low-pressure cylinder. The engine has a maximum overload capacity of 5,244 hp under normal conditions of 150 pounds steam and 26 in. vacuum. The overall dimensions of the unit are approximately 32½ ft. in height, 35 ft. in length and 15 ft. width for the engine alone; the flywheel being 23 ft. in diameter. A receiver connects the high-pressure and low-pressure cylinders. The engine is fitted with Corliss valves and "three-quarter" valve gear, with a new enclosed-type governor. Cylinders, valves and pistons are of special close-grained air furnace iron, and cranks, rods and pins are of forged steel, the shaft being forged hollow by hydraulic pressure. The shaft is 31 in. in diameter at the generator and 28 in. at the bearings, which are of the ball and socket self-aligning type. The guaranteed economy of the engines is 13½ pounds per 1 hp at the point of best efficiency. The speed regulation within small limits for paralleling the generators is effected from the switchboard through a motor-actuated weight on the governor lay-shaft, this motor being connected with a switch on the board.

The generators are rated at 2,000 kw at the usual temperature rise. They deliver three-phase current at 6,600 volts directly to a distributing system, without the introduction of intermediate transformers. Fifty per cent. overload may be carried for one hour without injurious heating. The armature frames are arranged to be moved parallel to the shaft in order to provide access to the fields, which are strap-wound, with laminated pole pieces. The guaranteed efficiencies of the Westinghouse unit, based upon measured iron and copper losses, are as follows, on the basis of 100 per cent. power factor: full load, 96 per cent.; ¾-load, 95 per cent.; ½-load, 93 per cent. Each machine, complete with bed-plate, weighs 196,000 pounds, the rotating member having a flywheel capacity of 5½ ft. radius, of 70,000 pounds.

The exciter units are standard Westinghouse engine-type machines, with field frames divided in a vertical plane parallel to the shaft. By separating the two halves of the frame, direct access may be had to the armature for inspection or repair. The guaranteed efficiencies of these generators, also based upon copper and iron losses, are as follows: full load, 91 per cent.; ¾-load, 91 per cent.; ½-load, 90 per cent.; ¼-load, 83 per cent.

The exciters are driven by twelve 20 x 12 Westinghouse compound engines operating at the regular boiler pressure and exhausting into the main condensing system.

The switchboard for the entire generating equipment will be located at the western end of the main aisle upon a raised platform. It will consist of thirty-five panels, four of which will be devoted to the main generators; three to the exciters; two to incoming feeders from the Union Electric Light and Power Company's plant; two are used for load panels, and twenty-four for outgoing feeders. The panels are of blue Vermont marble mounted upon steel framework with non-combustible bus supports and other standard approved fixtures. A duplicate set of bus-bars is employed, each having an individual load panel for totalizing the output. The main current will be controlled entirely by automatic electrically operated oil switches, operated from the main board. Shunt and series transformers are used with all indicating and recording meters. Each main generator panel contains the usual equipment of ammeters and voltmeters, also an indicating wattmeter, field discharging switch, and engine governor motor switch. Time limit relays will also be used for protecting the generator from prolonged short-circuits. The Westinghouse generator panels use a single polyphase indicating wattmeter, while the General Electric panels contain two single-phase indicating wattmeters, together with a recording wattmeter. Black oxidized copper forms the general finish of the instruments. The twenty-four outgoing feeder panels contain similar equipments and a single pair of high tension switches, part being of the Westinghouse hook type and part of the General Electric knife type.

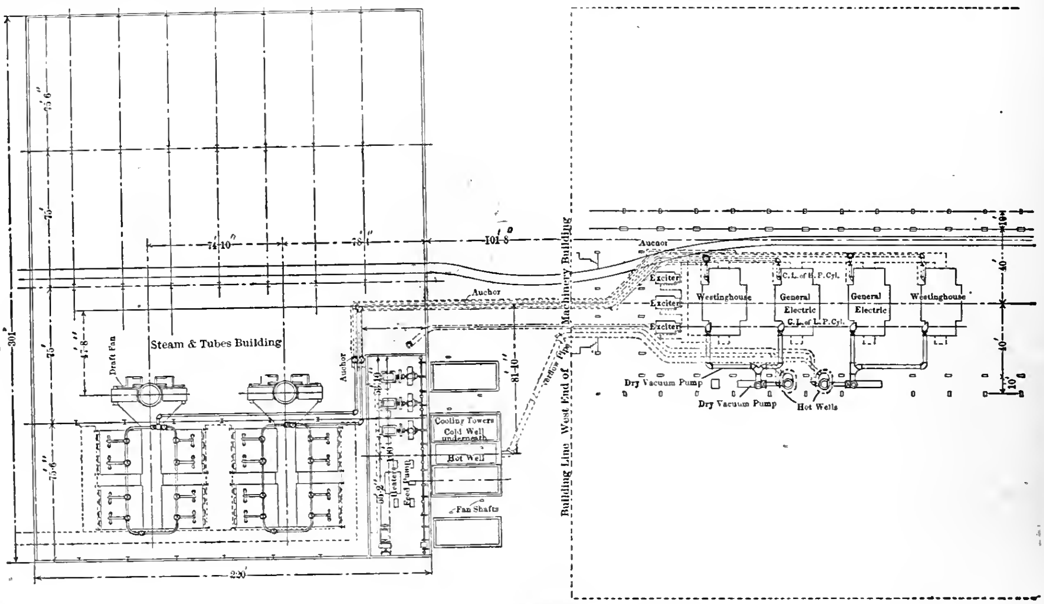

FIG. 2.—PLAN OF STEAM AND ELECTRIC PLANT.

BOILER PLANT.

Conforming with the duplicate construction employed in other parts of the plant, two complete steam generating outfits have been installed, each with independent flues, mechanical draft, steam and feed-water system. The capacity of the plant is 6,400 hp at the standard rating, uniformly distributed between eight batteries of boilers.

Each battery contains two 400-hp Babcock & Wilcox, inclined header, water-tube boilers built into a single setting. The boilers have 42-in. drums hung from a structural steel framework so as to be independent of the setting, thus relieving the brickwork from the stresses due to dead weight and differential expansion. The products of combustion discharge horizontally through the upper part of the setting into a single flue common to each section of the boiler equipment. The boilers are all fitted with Roney mechanical stokers driven by Westinghouse Standard engines, through worm gearing, each stoker engine operating two complete batteries of stokers by means of a shaft extending along the stoker fronts. The boiler plant furnishes steam at 150 pounds pressure without superheat.

Two spur tracks entering the Coal and Fuels Building along the western wall, will be utilized for handling coal and ashes. A complete conveying system, furnished by the Link-Belt Engineering Company, receives the coal from the hoppers located between the track rails, elevates and distributes it among individual bins, each serving one stoker through steel chutes. The system also conveys coal to a storage bunker of about 500 tons capacity, from which the coal may also be drawn for miscellaneous boiler and gas producer exhibits located in the same building. The individual bins in front of the plant boilers are supported by structural steel frames independent of the boiler columns. They each hold about five tons of coal and are circular in form with conical bottoms, the discharge being controlled by wing valves. The chutes conveying the coal to the stoker hoppers are arranged to swing about a horizontal axis in order that they may be swung back into a vertical position to clear the stokers and boiler doors.

Ashes from the stoker grates gravitate into concrete-lined pits, from which they are moved into ash cars running through tunnels beneath the floor. These tunnels connect with the cross tunnel outside the building, which rises to the surface.

The boiler plant is supplied with feed-water from the city mains, after passing through a duplicate set of 4,000-hp Cochrane feed-water heaters using exhaust steam from the boiler house auxiliaries. This heater is mounted 3½ feet from the floor upon a hollow concrete pier reinforced with expanded metal.

The battery of pumps located near the heater supplies the entire plant with feed-water. Two types are represented, viz., duplex outside-packed double-plunger, and the Admiralty type, both of Worthington make. Two of the former type are used, each 9 x 16 x 7½ x 15, and one of the latter, 14 x 10 x 18. These pumps discharge into a ring main in order that they may be operated singly or together, as desired.

MECHANICAL DRAFT PLANT.

Two complete mechanical draft plants have been installed, each serving eight boilers aggregating 3,200 hp, and a duplicate fan is provided for relay purposes.

The flue construction consists of concrete floors and brick ceilings supported by 2¼-in. x 2¼-in. tees which span the space between the rear walls of the boiler settings. As this space is about 10 ft. in width, a row of 4-in. pipe struts with I beam stringers supports these T beams at their centre. The ceiling is finished with two courses of common brick laid flat and flushed with cement This flue leads directly to the fan housings, the joint being sealed with a sleeve formed by angles riveted to the housings.

The fan equipment consists of two 14 ft. 12-blade steel plate fans mounted within a rectangular steel plate housing suitably strengthened with steel sections. These fans are of ¾-housed overhung pattern built from special designs of Westinghouse, Church, Kerr & Co. by the New York Blower Company. The central part of the housing supports the steel plate stack, which is 11 ft. in diameter, the whole resting on a concrete pier. The two fans operate in opposite directions, receiving the flue gases at their centre and discharging the periphery into the central compartment leading to the stack. A deflecting damper hinged at the center of this compartment provides means for isolating the idle fan as well as for insuring a continuous surface for the ascending gases from the fan in motion. The intake of each fan is closed when idle, by a steel plate damper 10½ ft. square, which is hung from rollers and may be shifted from one intake to another by means of a chain and hand-wheel. With the two dampers mentioned, each fan may be operated independently of the other, or if unusual capacity is required, the dampers may be placed in mid-position and both fans operated simultaneously.

Each fan is direct driven by a Chandler & Taylor 13 in. x 14 in. simple automatic high-speed engine controlled by a throttle governor. The fan bearing is supported by a cantilever I beam grillage, and is of the ring-oiling type protected from the heat of the flue gases by a water-jacket.

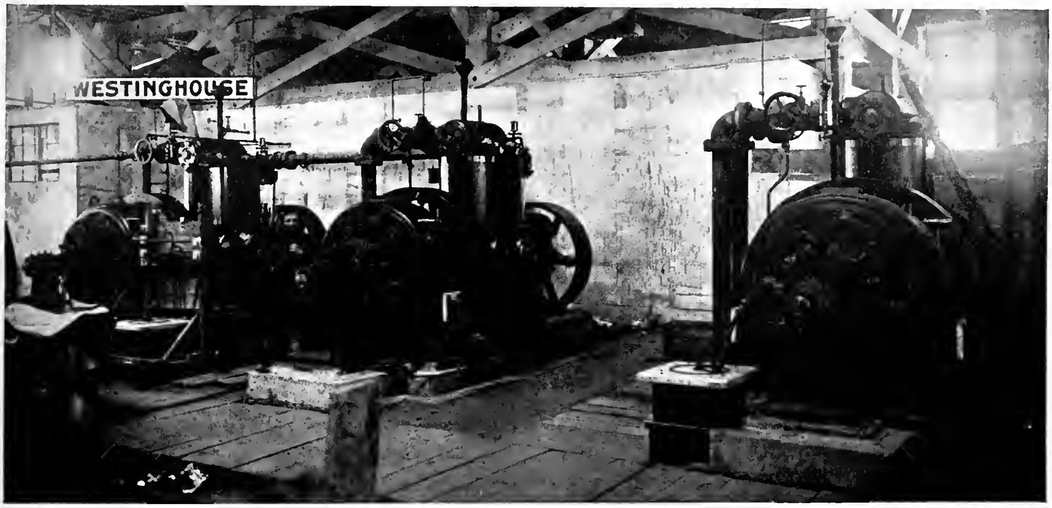

FIG. 3.—EXCITER UNITS.

CONDENSING PLANT.

The two condensing plants are practically duplicates, although each is intended to serve one-half of the engine plant. The condensers, which are 40 in. in diameter at the entrance, are of the Worthington elevated jet or barometric type. They are located in the space between building and crane columns in order to clear the crane. At the junction of the horizontal and vertical lines of exhaust piping is located a cast-iron entrainer which forms a water pocket draining the horizontal line and so directing the passing exhaust steam as to pick up any water collected in quantity in the pipe and carry it over to the condenser in the form of spray. At the top of each exhaust riser is an automatic relief valve which in event of loss of vacuum provides a vent to the atmosphere through a line of vertical spiral riveted pipe extending through the roof. A gate valve at each engine and at the condensers gives complete control of this part of the system. The weight of the condenser is borne by two 15-in. I beams spanning the concrete hot-well, lugs having been fitted on the tail pipe for furnishing the required bearing.

Injection water is supplied through a 30-in. cast-iron main from the pump room, two 20-in. risers leading to the two condenser cones. At this point is located on each condenser a tubular air cooler, around which the injection water circulates on its way to the condenser.

An important part of the condenser equipment are the dry vacuum pumps, the function of which is to extract from the condenser cones the entrained air which would otherwise impair the vacuum. This is drawn from the cone in the form of saturated vapor. The moisture is condensed in the copper tubes of the air cooler, leaving dry air for the pumps. Three pumps are furnished for the two condensers, one of which may be held as a reserve. Two of these are 10 in. x 22 in. x 18 in. of the horizontal rotative pattern, and the third an 8 x 16 x 12 vertical marine type high-speed pump, all of Worthington build. They are supplied with steam from the engine auxiliary piping system and exhaust into the main condensing system. The air discharge is led through spiral riveted piping to the roof.

The overflow water from the two condenser hot-wells is conducted through a 36-in. tile conduit to a concrete hot-well located about 200 ft. distant at the cooling towers. On account of the nature of the soil it was found necessary to support this conduit on piling. For this purpose the entire conduit line was enclosed within a timber trough 2½ ft. x 3 ft. deep, built of 4-in. pine tongued and grooved, this trough resting upon cross sleepers capping the double row of piles. The sides of the trough were reinforced and the structure held together by tie-rods.

COOLING TOWERS.

An interesting feature of the plant is the equipment of the cooling towers for furnishing cold water to the condensers. The arrangement of the battery of towers is shown in Fig. 2. The equipment is of sufficient capacity to supply the entire station, aggregating about 14,000 indicated horse power, including auxiliaries operating upon the main condensing system.

The four towers are identical in size and construction. Each consists of a rectangular brick stack 52 ft. in height, containing ten tiers of wooden gratings occupying 20 ft. of the height of the tower. These gratings furnish the cooling surface of the tower, and are constructed of 3 in. x 6 in. pine timber set on edge four deep, with uniform side spacing. This construction forms a horizontal grating 24 in. in height and filling the entire area of the tower. The ten tiers of grating are at right angles, in order to more completely break up descending streams of water and secure maximum effectiveness of cooling surface. A space of 12½ ft. beneath gratings provides for the introduction of the fans and a corresponding space of 20 ft. above the gratings conveys the vapor above the adjacent building roof and provides some natural draft in addition to that furnished by the fans.

The distributing system of each tower comprises a 20-in. cast-iron supply pipe extending through the walls of the pump room the full length of the towers. This in turn supplies thirty transverse distributing pipes drilled underneath with numerous holes, the entire pipe system being suspended from steel cross beams anchored in the walls. A 20-in. cast-iron main connects the four branches of the towers with the circulating pumps, each branch being controlled by a gate-valve. Underneath each tower is a settling well connecting with a central cold-well from which the condenser water is drawn.

Draft is supplied to each tower by four 120-in. Seymour fans arranged in two pairs, each driven by curved grates formed by wooden strips set on edge so as to permit clear descent of water to the settling-well beneath. All sixteen fans are belted to a jack-shaft with Neptune waterproof belt. This jack-shaft is carried by brackets attached to the building wall, and is driven by an 18-in. x 30-in. x 16-in. Westinghouse compound engine, the strain of the main belt being taken up by a structural steel tower built independent of the building wall.

Injection water for condensers and water for cooling towers is handled by a battery of three 24-in. centrifugal pumps of the Worthington turbine pattern, one being normally used for the two condensers and one for the towers, while the third is held in reserve. Either pump may be replaced by the spare when desired. These pumps are direct driven by 18 x 30 x 16 Westinghouse compound engines and operate upon a head of approximately 45 ft. including suction. Each pump unit is capable of delivering 17,000 gallons per minute under a total head of 50 ft. including equivalent friction head. The output of these pumps may be regulated according to the water required, by means of handwheels at the end of the engine shafts. These communicate with the respective engine governors, the adjustment of which may be changed while the unit is running, and the speed then proportioned to the load. The 24-in. water main supplying the tower is supported by 10-in. pipe columns with intermediate trusses.

PIPING.

Two complete and independent systems of high pressure steam piping have been laid out, one for each of the two main sections of the boiler plant. The four batteries of boilers constituting each section of the boiler plant are interconnected by a 10-in. main and a 4-in. auxiliary line, both in the form of a ring main. No pipe bends are used except on this ring main, the necessary flexibility of the piping system being secured partly by this means and partly by the method of support. Extra heavy Eaton-Cole & Burnham fittings and Chapman outside screw and yoke gates valves are used on all high pressure piping, and standard fittings on the low pressure piping. At the junction of the ring main and the various risers from the boilers, angle valves are used in the case of both the 10-in. and 4-in. mains.

With the location of the valves adopted in the event of rupture of any section of a ring main the trouble may be localized by shutting off the disabled section, the remaining half of the main being kept in service. The use of the ring main also largely facilitates the steam distribution.

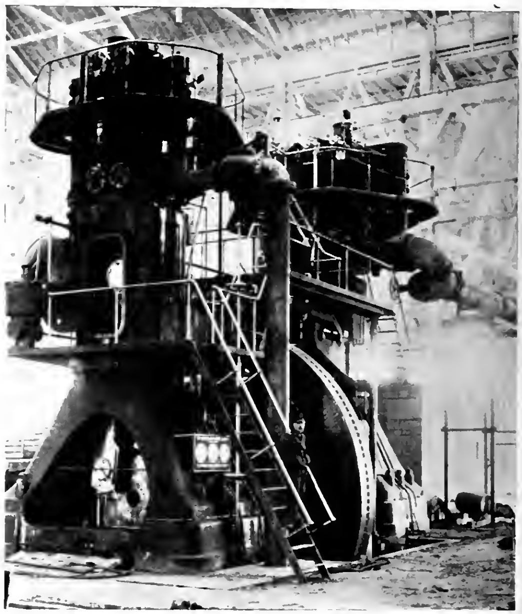

FIG. 4.—ONE OF THE GENERATING UNITS.

Each of the 10-in. ring mains connects with a 12-in. supply pipe leading to the engine room in the Machinery Building. The two 4-in. auxiliary ring mains similarly connect with an 8-in. supply main serving the boiler plant auxiliaries, together with the circulating pump and cooling tower engines. No connection exists at any point between the 10-in. and 4-in. systems; this separation being still more complete by the fact that the auxiliary ring mains are supplied by 2-in. taps into the boiler headers, thus rendering the operation of the auxiliaries quite independent of any break in the main piping system. As a precautionary measure in case of rupture to the 8-in. auxiliary supply line, a 2½-in. duplicate supply pipe also leads to the auxiliary room, so that sufficient steam may be available for operating the boiler feed pumps, thus keeping this part of the plant under control.

At the northwest corner of the auxiliary room, the two 12-in. engine supply lines drop approximately 28 ft. to the level of a pipe tunnel through which they are carried to the Machinery Building, a distance of about 475 ft. in the case of the longest run. The average length of run from the respective ring mains to the corresponding pair of engines supplied, is 464 ft. in one case, and 617 ft. in the other.

The entire high-pressure piping system in the boiler house is drained by a "steam loop" and Holly "gravity return" system, which automatically returns condensation to the boilers. This system not only drains the piping itself, but also the water-pockets in the various valves. Sectional magnesia covering is employed on all high-pressure piping, plastic material of the same composition being used for boiler drum heads and engine cylinders and receivers.

All boiler room auxiliaries, as well as the circulating pump and fan engines, exhaust into two Cochrane feed-water heaters in duplicate, the distribution of the exhaust steam between the two headers being controlled by valves, so that either heater may be replaced by the other one when desired. Both headers are provided with oil extractors at the point where the exhaust enters the heater. These largely prevent the oil carried over in the exhaust steam from contaminating the feed-water. The two heaters are provided in common with an atmospheric relief of spiral riveted pipe leading through the roof.

An unusually symmetrical arrangement of feed-piping is employed. The supply mains are in duplicate and have cross-connections at

FIG. 5.—PUMPS FOR CONDENSER INJECTION WATER.

adjacent batteries through 2½-in. headers. By means of properly located valves, each section may, however, be completely isolated in case of necessity. Ordinarily the feed line to each battery of boilers is controlled by a single valve.

In designing the supports for the various systems of piping, unusual difficulties have been encountered in the absence of facilities for hanging the pipes from the roof trusses, thus making it necessary to support all piping from the ground. In this work wrought-iron pipe columns and trussed pipe-towers have been largely used for carrying the elevated mains where these run clear of the boiler settings.

The problem of expansion in the long run of piping between buildings was solved by providing sufficient swing radius at bends and by anchoring at intermediate points. At the point of entry to the pipe trench, the two 12-in. mains are restrained from horizontal movement by the anchor, and at the corner of the succeeding run, 162 ft. in length, both lines are again anchored, as well as at the beginning of the last section of piping at the engines. At each bend in the steam lines double 90-degree elbows are employed, with short nipples, which form hinge joints through which sufficient flexibility is secured to relieve the fittings of undue strain.

At the points intermediate between anchors, roller supports are used. The weight of the pipe line is carried by 2½-in. wrought-iron pipe extending across the trench with ends set into wood blocks. The elevation of the support may be adjusted by wooden wedges. The steam pipes rest directly upon loosely fitting pipe sleeves which accommodate the expansion and contraction of the pipe line.

CONSTRUCTION.

Construction of the service plant was started about April 1, 1903, and the first main unit was turned over on December 29, 1903. The entire plant is nearing completion and will be available for service well in advance of the opening of the Exposition, in May.

Failure to Deliver Telephone Message.

A novel and interesting question, or rather a new aspect of an old point, was disposed of recently by the Supreme Court of Mississippi, on appeal, when it decided that the Cumberland Telephone & Telegraph Company was not liable for failure to deliver a message, although held so by a lower court. Chief Justice Whitfield remarked: Section 4326 of the Code of 1892 is a highly penal statute, and must be strictly construed. We are clearly of the opinion that the only messages or matter referred to in that section are written or printed messages or matter. The very language of the statute clearly indicates this. The messages or matter the failure to transmit correctly and deliver which subjects the telegraph and telephone companies to the penalty therein provided are declared to be messages "addressed to a person," etc. These messages, it is said, must be transmitted correctly; that is, correctly as written. "To transmit correctly and deliver the same"—that is, the messages or matter so addressed—is the precise language used. It may be true that a large part of the messages or matter handled by a telephone company is orally delivered as the business is actually conducted, but the question is what character of messages or matter this particular statute describes when it provides the penalty for the failure to correctly transmit and deliver such messages or matter. The statute itself is very imperfectly framed as regards telephone companies, for there is a manifest difference in some respects between the nature of the businsses conducted by the two companies, as the respective businesses are actually conducted; and this defect or imperfection in the statute, as it relates to telephone companies, properly calls for an amendment by the Legislature. It is our business to construe the statute strictly as it is now framed, and under the familiar principles of construction applicable to penal statutes we are of the opinion that what took place here is not within the purview of the statute.

As stated in Western Union Telegraph Company vs. Dozier, 67 Miss. 291, 7 South. 326, 'The very expression as to a message delivered to be sent carries with it the idea of a written or printed message'; and so here the very expressions to which we have referred clearly indicate that as to telephone companies, as the law now stands, only those which are written or printed come within the purview of this statute. There was nothing here but a mere call, the object of the call being to secure the presence of parties at the telephone, and to communicate with them as desired. Until the Legislature shall so amend the law as to make it clear that this sort of matter orally delivered and transmitted is meant to be dealt with in this penal fashion, the penalty cannot be recovered.

Service Tests of Motor Wagons.

The Automobile Club of America will hold, during the week beginning April 4, 1904, a service test of motor wagons. The test will be open to motor wagons used for commercial purposes made in the United States or abroad. The classification will be on the basis of dead load carried—all wagons of light weight, whether steam, gasoline, or electric, to operate in the same class. The following classes have been established: 1st. To carry a dead load of 1,000 pounds or under. 2d. To carry a dead load of 1,000 to 2,000 pounds. 3d. To carry a dead load of 2,000 to 3,000 pounds. 4th. To carry a dead load of 3,000 to 4,000 pounds. 5th. To carry a dead load of 4,000 to 5,000 pounds. 6th. To carry a dead load of 5,000 to 6,000 pounds.

With a view of holding a more thorough and practical test than has heretofore been afforded, the wagons will be placed under actual working conditions in the service of the American and Westcott Express companies for one week from April 4 to 9, inclusive, and will transfer and deliver merchandise, produce, baggage, etc., from the various depots of these companies during the entire week.

Awards will be made in each class for the best performance, based on the economy of operation in time and fuel, ratio of paying load, ton mileage, and general reliability and availability for service.

Entry blanks and further information may be obtained from the club secretary, Mr. S. M. Butler, 753 Fifth Avenue New York.

Meeting of the Ohio Independent Telephone Association.

At a three-days' session held at the Grand Hotel, Cincinnati, February 17 to 19, the Ohio Independent Telephone Association was practically reorganized and placed on a substantial basis. For three years, due largely to the financial difficulties of some of the largest interests in the State, the Ohio Independent Telephone Association has been practically inoperative. The meeting in Cincinnati was called for two reasons: To reorganize the association and to aid the independent interests that are working for a foothold in Cincinnati, this being the only large city in Ohio and in the central district without the independent service. Over 200 telephone men were present, including managers of over 100 companies in Ohio, with a few invited guests from points in Indiana and Kentucky, together with a number of the ubiquitous supply men.

A review of the state of affairs in Cincinnati revealed a rather peculiar condition, but a not altogether disheartening one for the independents. The Cincinnati & Suburban Bell Telephone Company has a fair-sized list for a city of this size, and its rates are high. The strong point in its armor is the fact that about 65 per cent. of its stock is owned by local capitalists, who control other public service corporations in the city. The independents are divided; four companies seeking a franchise at the present time. The Queen City Telephone Company, headed by George Bears and Harry Gates, has a capital stock of $1,000,000, and claims to have secured 2,000 subscribers. The Cincinnati Telephone Company is headed by Powell Crosley and George Fletcher, of Toledo, and has no list. The Interstate Telephone Company, headed by S. Kinnon, operates in Kentucky and has lines extending to points opposite Cincinnati. The Fitzsimmons Telephone Company, headed by T. Fitzsimmons and D. J. House, claims to have an operative franchise and has about 200 telephones connecting hotels and business houses in the city. Its efforts to extend its system have been thwarted and the legality of its grant is doubted. At present the applications of all the companies are before the Probate Court. It was the general sentiment at the convention that the rival interests ought to get together and present a solid front. The establishment of an exchange in Cincinnati is of great importance to the independent interests all over Ohio and those of southern Indiana and northern Kentucky, and much development is being hindered by this lack of connection. On the other hand it was also demonstrated to Cincinnati people that they were losing an immense amount of business through lack of connection with the independents. Numerous telephone managers testified that people in their cities were using the independent lines and telephoning orders for goods to other centers. It was alleged that the independents in Ohio have 85,000 telephones, while the Bell companies have only 66,000 telephones, including Cincinnati.

Mr. J. B. Hoge, of Cleveland, representing the Federal Telephone Company, the United States Telephone Company and the Cuyahoga Telephone Company presented the first paper, reviewing in an interesting way various features of the independent telephone movement already familiar to our readers. Mr. Hoge displayed several maps showing the independent toll lines of the Central States and the main trunk lines in the entire United States. Trunk lines extend as far east as Albany, N. Y.; Pittsburg, Philadelphia and Buffalo being connected up. Between Erie and Dunkirk there is a short gap now being filled, but from Erie there are unbroken lines all over Ohio, Michigan and Indiana. Illinois, Iowa, Minnesota and Wisconsin are well supplied and there are lines running down through Missouri and Indian Territory reaching a number of points in Texas. On the Pacific Coast there is considerable development, and some in the New England States.

Mr. Frank Beam, of the Columbus Citizens' Telephone Company, pointed out that the independent movement started in Ohio and that the National and Interstate associations were the outgrowths of the Ohio association, which was organized in 1895. He maintained that the future of the independent movement depended upon the extending of long-distance lines and the connecting up of all independent companies. He claimed that general business conditions were absolutely different from what they were five years ago. Formerly the business man transacted his business by telegraph. Now he calls up his man by telephone and talks with him direct. The inability of the local long-distance company to furnish the desired connection, counted against the entire independent movement in every instance. Through the inability of the United States Telephone Company to extend its toll lines, Mr. Beam stated that his company in Columbus was obliged to turn away almost as much long-distance business as it takes on. Columbus should have at least 35 additional circuits to relieve overcrowded lines to numerous points in Ohio. He urged the various independent managers to offer to take stock in the long-distance company and said that that company would be willing to spend the money invested in the county or locality served by the investor. He said that even under present conditions practically no extensions having been made in three years, the United States Company was earning fine profits and offered an excellent investment. He also urged the Cincinnati people to get together and stated that prominent Ohio companies would undoubtedly be willing to take stock in a single Cincinnati company, because an exchange in that city would aid their business. He said that with independent service, Cincinnati merchants would have five times as many calls as at present and he thought they could well afford to pay the additional $60 per year for another telephone.

Mr. Miller, who has just left the Bell Company after eight years of service, to become manager of the Dayton Home Telephone Company, also urged the importance of extending the long-distance systems. He stated that the Bell people formerly confined their efforts to working the large cities, but they are now building up the toll business. The Bell people now have a large number of men at salaries ranging from $100 to $200 per month, selling long-distance coupons all over Ohio. He claimed that in Columbus alone over $65,000 worth of these coupons had been sold in two months. Dayton, Columbus and other cities were losing the business through lack of connection with Cincinnati. He urged that pressure be brought to bear to induce local merchants to patronize jobbers in other centers than Cincinnati, and he said the Cincinnati merchants would soon awaken to the importance of having independent connection with these people. He thought this plan would be very effective because many of the local merchants are stockholders in independent companies.

Mr. J. B. Rhodes, of Zanesville, presented a paper on "Party Lines." He said that for a modern exchange of say 2,000 subscribers the average cost of construction should not exceed $200 per individual line. If for such a plant the residence rate is $24 per year, the gross earnings would be 12 per cent. of the amount invested. By equipping such a line with four-party service, the investment, including four instruments, should not exceed $230. If a rate of $15 is charged for four-party service, the revenue would be equal to 26 per cent. instead of 12; but as a conservative estimate would place the average number of telephones on a line at 3 instead of 4, this would doubtless in practice be reduced to something over 20 per cent.

The rates for farm line service in Ohio usually range from $1 to $1.50 per month, which, considering the initial investment and the cost of maintenance, yields a smaller return to the stockholder than any other class of service. But for a distance of from five to ten miles from exchanges where troublemen are at all times available, the service can be profitably handled at these rates; but in most counties there are numerous residents in districts more remote, who are equally anxious for service. Many of these districts are from fifteen to twenty-five miles from an exchange, which renders it very difficult and expensive to handle them. From the company's point of view, it would seem that a schedule of rates proportionate to distances should be established; but unfortunately for the company, the farmer in remote territory is not inclined to accept this solution. The most feasible method by which such business may be handled is to allow the farmers in such districts to construct and operate their own lines and provide some equitable arrangement for interchanging business with them. If managers will interest themselves in such development they can usually govern not only the method of operating, but the purchase of apparatus and the character of construction which, if accomplished, will render the service almost, if not altogether, as reliable and satisfactory as that furnished by the telephone company. When arrangements of this kind are made the telephone company should own and operate the necessary switchboards and charge a switching fee that will be sufficient to defray all necessary expense, and yield a reasonable return for the amount of capital invested.

The discussions on this paper were spirited and developed a wide range of ideas as to the most desirable practice. They also demonstrated that in some sections there has been a tremendous growth of farmers' community systems, many of them operating on the co-operative plan.

Mr. Chambers, of Winchester, Ky., said the company had 300 telephones in the country. They put up party lines using six on a line with divided circuits. They charge $5 per year per mile for building and maintaining the lines, dividing the amount among those on a single line. They furnish the telephones for $1 per month.

Mr. Beam, of Columbus, favored a uniform rate. His company has a selective ringing and lock-out system, which is giving good satisfaction with six on a line; rate $15 per year. He urged that some standard form of selective lock-out system be generally adopted and suggested that at the next meeting committees be appointed to work on standardization. He said any system should have 50 per cent. farmers' lines. For individual farmers' lines his company charges $8 per mile in addition to the rate in the town.

Mr. Miller, of Dayton, reported 700 farmers' lines in Clark County. They have seven small exchanges in various corners of the county with trunk lines from each leading to central. The rate to farmers is $1.50 per month. The small boards are in a residence or store and the attendant is paid $20 per month to answer all calls. From six to ten are placed on a circuit and the circuits average three miles. They give free service throughout the county and for city calls as well.

The Franklin County company reported fourteen exchanges in country towns. They charge $24 for business and $12 for residences and $15 for farmers. Six telephones are placed on a line. Free service is given throughout the county except to Columbus. Farmers calling Columbus frequently pay a flat rate of $12 per year additional and have individual service. A charge of 10 cents per call is made to those who call the flat rate people.

Mr. Lasher, of Rutland, represented the Farmers' Mutual Company, which has 2,000 subscribers connected with fifteen small exchanges. Each subscriber pays $2 for initiation fee and pays 15 cents per month towards an operator. He buys his own telephone and builds his own line to connect with the next farmer. Not less than 100 farmers are connected with a board and from nine to sixteen telephones are placed on a line. Each district maintains its own repairs. Free connection is given throughout the fifteen exchanges. The system connects with an exchange at Athens, and a portion of the subscribers have secured connection with the Bell system.

Mr. Resinger, of Gallipolis, told of a farmers' mutual system operating in four counties and connecting with Gallipolis. Over 3,000 farmers are now connected up. Fifteen farmers organize a division, build their own lines, buy their own telephones and install a small switchboard. Each pays 10 cents per month for board service, and they have free service throughout the entire district. The Gallipolis company has made contracts with about 250 of these farmers who build their own lines to the city limits and pay $1 per year, giving them connection in Gallipolis. Outgoing messages are charged 10 cents each. Through these lines others on the mutual system can reach Gallipolis and they pay 10 cents for each message.

Several prominent delegates talked strongly against farmers' mutual systems, as they claimed they were not properly maintained and were a detriment to the independent service. It was the general expression that the company at the county seat should thoroughly cover its own county and that free service should not be extended throughout the county.

Mr. Davis Prewitt, of Winchester, Ky., presented a paper entitled "Consolidation," outlining a plan of organization and union, on a kind of federated basis, with delegates in an upper and a lower chamber.

Mr. J. B. Hoge, in discussing the plan of a central organization, thought that State lines should be disregarded and that in forming divisions the companies should be grouped around large cities. He thought it would be advisable to consider the toll business to various centers and place a company in the division to which it contributed the largest amount of toll business. The plan outlined by Mr. Prewitt brought out considerable discussion and it is probable that something tangible will develop from his ideas.

In the general discussions which followed, W. Gilbert Thompson, president of the association, took occasion to warn the independent managers against making alliances with Bell companies. He stated that the Bell people were now working among the independents and were willing to furnish connection with almost any company, particularly in the vicinity of Cincinnati. At many points in this district they are offering the farmers free connection with the nearby village as well as free connection with Cincinnati.

Mr. J. B. Hoge, of Cleveland, gave the history of the recent order of the Postmaster-General requiring postmasters to subscribe for only that telephone which reached Washington, which of necessity meant the Bell Company. He stated that in view of the strenuous objections made by the independents, this ruling had been modified to the extent that the department would consider upon their merits any applications made by independent companies. A committee composed of F. S. Dickson, Cleveland; Cyrus Huling, of Columbus, and E. L. Barber was appointed to oppose this ruling before Congress, if necessary.

A committee on permanent organization was appointed and in its report it asked that the present temporary organization be continued and that another meeting be held in May, when a permanent organization would be effected. Adopted. The present officers who are continued are: W. Gilbert Thompson, Lebanon, president, and E. E. Knox, Portsmouth, secretary. These gentlemen will act with the committee on permanent organization.

The committee on credentials advised that managers of Ohio, Kentucky and Indiana, and manufacturers of supplies, be admitted to membership. Only Ohio managers to vote on Ohio matters and on election of officers. The matter was left open until the next meeting.

The committee on legislation reported that two bills were now before the Ohio Legislature and advised that the association oppose both of them. House bill 166 provides that telephone companies desiring connection with other telephone companies may secure same, and that the company desiring the connection shall build the connecting link and stand the expense. That the connected companies shall not charge more than they charge their own subscribers. It was claimed that the bill was introduced in the interests of a farmers' system that was endeavoring to force a connection with an independent company on an unfavorable basis. It was the sense of the convention that the bill was indefinite and ambiguous, and it was voted to oppose the bill.

House bill 149 is designed to regulate price and provides that rates shall not exceed $3 for residence telephones and $6 per month for business telephones. It was stated that this bill would not affect any of the independent companies in the State at the present time, but it was pointed out that in cases where manufacturing establishments at a distance from a large city wanted telephone service, the bill would make it possible for them to demand the maximum rate mentioned. It was voted to oppose this bill and delegates were requested to communicate with their representatives to help defeat both measures.

A novel feature of the programme consisted of musical selections between the various papers. In place of the usual banquet a smoker and vaudeville entertainment was given in the banquet room of the Grand Hotel. Friday was devoted to the inspection of exhibits.

A. I. E. E. Meeting.

The regular monthly meeting of the American Institute of Electrical Engineers will be held at the Chemists' Club, New York, Friday, Feb. 26, at 8.15 P.M. The following papers will be presented and discussed: "European Practice in the Construction and Operation of High-Tension Transmission Lines and Insulators," by Guido Semenza, Chief Electrical Engineer of the Italian Edison Company, of Milan, Italy; "Conductivity of the Atmosphere at High Voltages," by Harris J. Ryan, professor of electrical engineering, Sibley College, Cornell University, Ithaca, N. Y.

Farmers' Telephones in Winter.

The farmers' telephone was a boon during the recent heavy and unprecedented snows, and many interesting uses are reported in New York State in places where many roads were blocked with drifts over 10 ft. deep. Hemmed in so that they could not see a neighbor for weeks, farmers have been able to converse with their friends and thus keep in touch with the world. In some instances they have reported cases of sickness to the doctor in town and have obtained advice about care of the sick and the administration of such simple remedies as they might have at home. On one of these circuits in Otsego County all the families having telephones have received frequent treats from Mr. William Cushman, a farmer, who last summer bought a fine Edison phonograph. He calls up the families on the circuit and they open the receivers. Then he sets the phonograph up to the transmitter and sets it going. Its records are thus heard over miles of country by a widely scattered audience.

Telephone Transmitters.—VI.

By Arthur V. Abbott, C. E.

The Wilhelm Transmitter.—The Wilhelm transmitter assembled is shown in Fig. 43. It resembles the Ericcson and Stromberg-Carlson by consisting of a brass case 2⅜ in. in diameter x 7/16 in. thick, made of pressed sheet metal. In Fig. 44 the instrument is opened. The diaphragm consists of sheet iron 2 3/16 in. diameter and .018 in. thick, supported upon a blotting paper ring and held in place by two 2-point brass springs .023 in. thick and .105 in. wide. There are two carbon electrodes each ¾ in. diameter. The front electrode is secured to the diaphragm by means of a screw passing through its center and contains eight circular pockets around its circumference. The rear carbon is of the same size and similarly secured to the case by a screw through the center. It, however, has a series of concentric circular grooves. Around the rear electrode is a piece of felt, something like a circular lamp wick, which is tied to the electrode. This forms a capsule which is filled with 15 grains of granular carbon.

Double-Diaphragm Transmitters.—In the archives of the Patent Office a number of devices for transmitters are recorded that seem to possess both originality and merit along lines other than those embodied in the solid backs, but for some unexplained reason few of such instruments have found their way into practice. In fact, the double-diaphragm transmitter forms about the only exception. The principle of the solid back is to provide an immovable anvil on which one electrode rests, in front of which the diaphragm carrying the other electrode is placed, perpendicularly to the direction of the sound waves. In the double-diaphragm models each electrode is placed on a mobile diaphragm, which is set parallel to the direction of the sound waves, and both are expected to vibrate.

FIG. 43.—WILHELM TRANSMITTER ASSEMBLED.

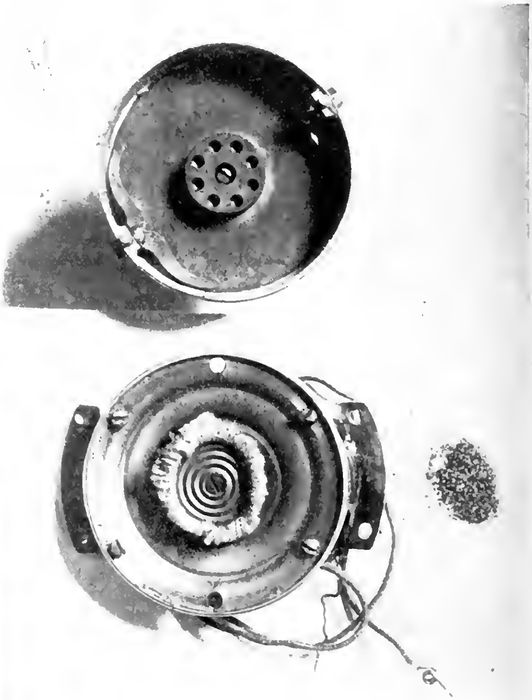

FIG. 44.—WILHELM TRANSMITTER OPENED.

The essential features of most double-diaphragm instruments are illustrated by the model of Fig. 45. There is a drum-shaped case, *A*, to enclose and protect the mechanism, provided with a sound-receiving funnel, *A′*. In the center of the case a ring, *D*, is fixed. On each face this ring is recessed to receive diaphragms *B* and *B′*, which may be of either carbon or metal. To the center of each diaphragm is secured an electrode, *b*, usually of carbon, around which is placed an elastic ring of felt, *b′*, and the space between the electrodes filled with granular carbon. In the model of Fig. 44 there is a septum, or partition, *C*, in the center, and the ring, *D*, is made in two parts, thus this instrument is really two transmitters placed back to back. One battery wire, C^2, runs to the center partition and the other to *C′*, to both diaphragms. There are no damping springs and by making the diaphragms very light and properly proportioning them to the resonant cavity an instrument of great power and delicacy of articulation should be produced.

In Fig. 46 a different design is shown. The two diaphragms, 3-3, supported by the rings 2-2, form the sides of a resonant chamber, into which the sound funnel, 11, opens. The carbon electrodes, 5-5, are bolted to the center of the diaphragms, and surrounded by a flexible fibrous wrapping, 7, while the cavity thus formed is filled with granular carbon. The simplicity and cheapness of such designs is certainly remarkable.

The Fahnestock Transmitter.—The transmitter manufactured by Fahnestock Transmitter Company, represents the latest and in many respects the highest development in transmitter building. The assembled instrument is shown in Fig. 47. There is a base 4 in. long 2 in. wide, to which a swinging arm 6½ in. long is pivoted, that provides reasonable range of motion to the mouthpiece. The base carries the induction coil in local battery instruments. On the end of the arms there is a rectangular chamber 1⅝ in. x 1⅝ in. x ¾ in., which is surmounted by the usual rubber voice funnel. The rectangular chamber contains the talking mechanism. Fig. 48 shows the instrument dissected. There are seven principal parts. The arm, *A*, mouthpiece, *B*, button, *C*, cover, *E*, mouthpiece ring, *D*, and screws, *F*. The end of the arm carrys the rectangular cavity into which the button, *C*, is placed. The cover, *E*, is then set over the button and secured with the screws, *F*. Finally the mouthpiece, *B*, is screwed into the cover, *E*, the ring, *D*, serving to take up any slack. Fig. 47 is a phantom drawing showing the button in place and the circuit connections. The speaking mechanism is shown in detail in Figs. 50 and 51. There is a metallic block, *A*, *A′*, 1½ in. x 1½ in. x 7/16 in. recessed as at *A* on both sides. In each of the inner recesses a disk of mica is placed to which a gold-plated electrode is secured, and which is fastened in place by the ring, *C*, as shown at Fig. 50. Each electrode carries a brass stud to which an aluminum diaphragm is attached. The outside of the diaphragm is shown at *B* and the inside, with an electrode in place at *B′*. Around the edge the diaphragm is dished to fit into the recess cut in the block, *A*. The space between the electrodes is filled with granular carbon and the rings, *C*, squeezed into place, making an air-tight joint. Then each diaphragm is secured to its studs by the nut, *F*. The recess in the block is cut so large that the diaphragms do not *touch anything* except the stud that holds them to the electrode, hence there is nothing to impede or distort their vibration. Finally to prevent the sound waves from affecting both sides of either diaphragm, the joint between the diaphragm and block is sealed with a thick solution of india rubber. From each electrode an insulated wire runs to a screw on the top of the block as at *A'*. These screws connect to leading-in wires shown in Fig. 48. From an acoustic standpoint, instruments of the double-diaphragm type would seem to present many possibilities of which inventors have not as yet fully availed themselves.

The Design of the Microphone.—The essential part of the transmitter is the contact. Some transmitters use metal electrodes, and give excellent results, but on the whole experience is inclined to favor all contacts of carbon, and certainly so far no other substance has been found that is even approximately as good.

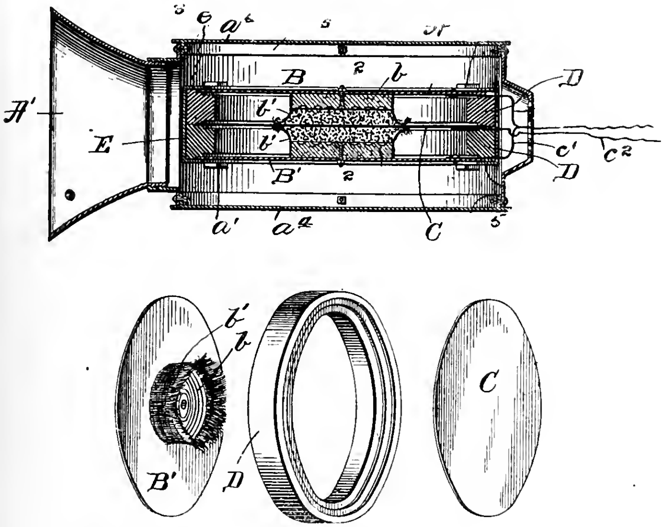

FIG. 45.—DOUBLE DIAPHRAGM TRANSMITTER, MODEL 1. (FULL SIZE.)

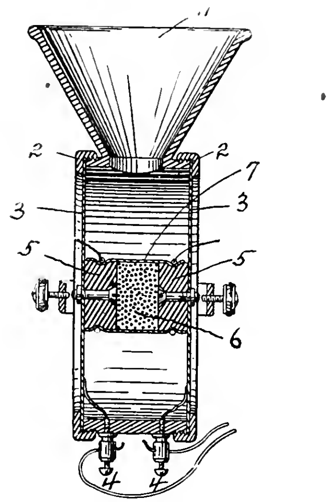

FIG. 46.—DOUBLE DIAPHRAGM TRANSMITTER, MODEL 2. (FULL SIZE.)

FIG. 47.—FAHNESTOCK TRANSMITTER ASSEMBLED.

FIG. 48.—FAHNESTOCK TRANSMITTER DISSECTED.

The most common form of electrodes is a flat carbon plate, ranging from ¼ in. to 1 in. in diameter, and from 1/16 in. to ⅛ in. in thickness. Electrodes should be made of the hardest densest carbon; those which are soft may be greatly improved by repeated boilings in a very dense solution of sugar, after each of which the carbon disc should be placed in a crucible covered with charcoal or carbon dust and heated to a bright red. Many other forms of electrodes have

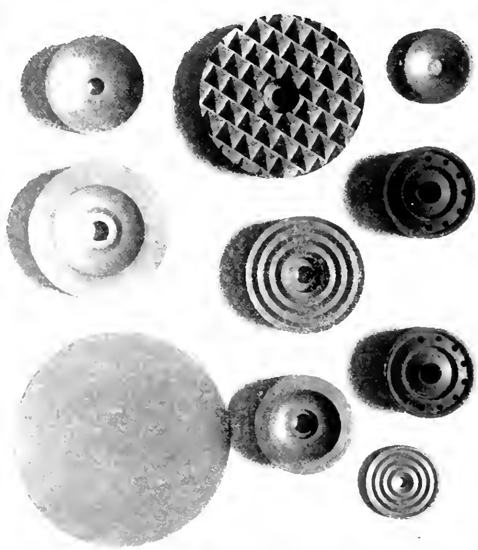

FIG. 52.—CARBON ELECTRODES.

FIG. 53.—GRANULAR CARBON MAGNIFIED.

TELEPHONE TRANSMITTERS.

been tried with varying degrees of success. Some such forms are illustrated in Fig. 52. About the granular carbon itself a cloud of mystery has always hung. But it is after all a simple matter, though to produce the best variety requires some practice. The National Carbon Company and Pinnar, of New York, furnish excellent products. Fig. 53 shows four samples of granular carbon magnified about eight diameters. Samples *A* and *B* are so-called No. 24; that is to say, are sized through a sieve with twenty-four meshes per linear inch. Samples *C* and *D* are No. 50 carbon. Most transmitter builders prefer to have both the electrodes and the granular highly polished. Electrodes can be surfaced by any of the well-known methods of polishing. An excellent way is to use carbon dust on a flat lap, with a final finish of crocus or putty powder. But to receive a remotely satisfactory surface the hardest and densest carbon must be used. With the granular polishing is much more difficult, because the sharp edges of the granules should be as far as possible preserved. In Fig. 53 *A* and *C* are specimens with dull finish and *B* and *D* are polished. One of the most important points is careful sizing as a prevention against packing, for the best preventions against this difficulty are to provide for room around the electrodes; use a thin layer of granular, which has by repeated sifting been sorted till all the particles are as nearly as possible of the same size.

New Telephone Patents.

AN IMPROVED COIN COLLECTOR.

Coin-collecting attachments for public telephone stations have been undergoing great improvement, change after change having been introduced to correct defects which practical service has indicated. The separation of the cash and mechanism compartments to prevent temptation getting the better of the inspectors and the provision of good locks upon the cash compartments were among the early improvements. These were followed by the perfection of distinctive audible signals, and automatic coin return apparatus. The turn now taken is toward the abandonment of audible signals altogether and instead of making the deposit of the proper coin necessary in order that the central office may be signaled at all.

This latter tack is that which has been followed by the American Telephone & Telegraph Company, its coin-collector having been developed primarily at the hands of Messrs. Bullard and Scribner and lately improved by S. J. Larned, of Chicago. It may be well to

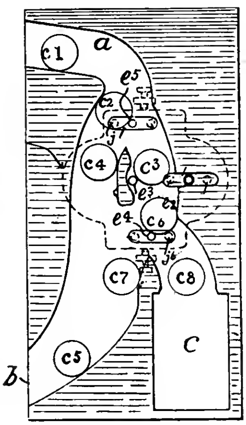

FIG. 1.—LARNED COIN COLLECTOR.

describe the apparatus in its present form, i. e., as it is disclosed in a patent recently issued to Mr. Larned.

The control of a coin is accomplished first by the peculiar contour of the coin slot, clearly shown in Fig. 1, and secondly by three pins, e^3, e^4 and e^5, mounted upon the tilting armature of a polarized electromagnet (outline dotted) and projecting into the coin slot. The various circles marked c^1, c^2, etc., show different positions which a coin may assume, in its course through the machine. The coin, c^1, just deposited rolls down the slot until it strikes the pin, e^5. If this latter is in its normal or unactuated position the coin will be deflected to the left as at c^2, c^4, c^5, and be returned to the depositor at *b*. This coin route corresponds to some error of condition in the apparatus. Such an error would be that of a failure of the user to remove the receiver from the hook. Another would be the failure of current to reach the instrument through any disability of the line or apparatus. Such a disability will prevent the proper signalling of the operator, and it is, therefore, just that a deposited coin be at once returned. This latter feature is one distinctive of the present improvement. Let us suppose, however, that everything is in working order. Then the pin, e^5, will be in the position j^1, the armature to which it is fastened having tilted under the influence of a circuit closed by the rising switch hook. The coin will then fall to the position c^3, where it closes a circuit between pins c^3 and e^2, this a shunt upon a high resistance included in the signal circuit. The reduction of resistance of this circuit consequent upon this shunting action permits the flow of sufficient current to actuate the line relay and signal. When the operator responds in the usual way, the circuit changes permit the armature of the collector magnet to return to the mid-position. This brings pin e^4 in the middle of the slot, obstructing the slot entirely, and at the same time causes pin e^2 to release the coin, which falls to position c^6. The operator now is in communication with the caller. If she succeeds in completing the desired connection a key provided for her enables her to move pin e^4 to throw the coin into the cash box. If, on the other hand, the call fails, the coin can be returned at *b* by the mere sending out of a reversed-current impulse.

NEW SWITCHING KEY.

In Fig. 2 is shown a side view of a combined ringing and listening key for switchboard use, which has been patented by J. S. Goldberg, of Chicago.

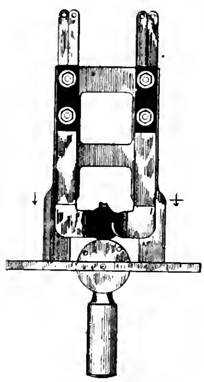

FIG. 2.—GOLDBERG SWITCHING KEY.

Aside from the neatness of design, the most notable feature is the method used for preventing disturbing effects from overtravel of the key plunger when this is being restored to the mid-position. For example, suppose an operator, after "listening in" on a circuit restores her key so that it overtravels. If this is one of the usual keys the middle springs of the ringing part may momentarily, under the influence of the plunger, clear their normal contacts and make a click upon the line. Mr. Goldberg makes his mid-springs on the ringing key much stronger than those of the listening key, so that any energy stored in the cam by the latter will be quickly absorbed by the former. The slight motion which is imparted to the middle ringing key springs is then rendered of no effect, because the line of resistance of the springs is so offset from the line of application of pressure from the cam that a considerable motion of the latter is required in twisting the springs before any outward motion of them away from their contacts occurs. The Stromberg-Carlson Company has obtained this patent by assignment.

DESK STAND SET SUPPORT.

A swinging desk stand support is the subject of a patent which has been granted to J. S. Detrick. This is a counter-weighted shelf support arranged to swing in a vertical plane and suspended in a frame attached to the ceiling. By pull chains the shelf may be swung down for use or pulled up out of the way.

TRANSMITTER HANGER.

A transmitter hanger for supporting switchboard transmitters forms the basis of another patent of recent issue. This hanger is pressed up out of sheet metal. At the top is a cross-bar with perforations through which the cords may be tied. From this two legs project downward, one perforated to be clamped to the transmitter front by the mouthpiece, and the other adapted to be fastened to the rear of the transmitter by screws. The patent for this hanger has been issued to M. Setter, of Chicago, and has been assigned to the American Electric Telephone Company.

Meeting of Wisconsin Independent Telephone Association.

This meeting, held at Milwaukee, on the 10th and 11th of February, was the fifth annual convention of the Independent Telephone Association of Wisconsin. About 75 companies were represented. There were two papers read, one on "Improvement in the Telephone Service," by Prof. G. W. Wilder, professor of telephony in the Armour Institute, Chicago; and one on "Legislative Prohibition of Discrimination in Telephone Rates," by Mr. J. C. Harper, president of the Dane County Telephone Company, Madison. The Green Telephone & Electric Company, of Milwaukee, was suspended from the association as its proprietor, Senator J. H. Green, of that city, had been so actively opposed to all legislation sought for by the independent companies in the State and had labored so hard in behalf of the Bell Company. Resolutions were adopted strongly censuring the Postmaster-General, H. C. Payne, for issuing an order some time ago by which many post-offices throughout the country had been ordered to use only the telephone service giving communication with Washington. A committee of six was appointed to look after telephone legislation at the next session of the Legislature. Nine companies were received as members at the meeting. A committee of three was appointed to arbitrate whatever disputes might arise between companies. A committee of three was appointed to interest the citizens of Milwaukee in the installation of an independent exchange. It was decided to hold the next annual convention in Milwaukee on February 9th and 10th, 1905. The secretary's report showed the continued rapid growth of the independent telephone business in the State, and of the association, which now comprises about three-fourths of the independent telephone interests in Wisconsin. During the past two years 90 new telephone companies were incorporated in the State with $1,500,000 of capital, and to-day Wisconsin has 250 independent telephone companies with an investment of $3,500,000; 1,200 toll stations, 350 exchanges and 35,000 subscribers, of which number 8,000 are rural subscribers.

The following officers were elected for the ensuing year: Richard Valentine, Janesville, president; H. G. Slater, Waupaca, vice-president; H. C. Winter, Madison, secretary and treasurer. Members of the executive committee—C. W. Twining, Monroe; G. Huette, Sheboygan; J. C. Harper, Madison; W. F. Goodrich, La Crosse; Julius Thielman, Merrill; John M. Baer, Appleton; E. A. Miller, Hixton; J. C. Crowley, West Superior.

The Independent Telephone Association of Wisconsin was organized at Weyauwega, March 21, 1900, since which time it has held eight meetings. The objects of the association, as stated in the constitution, are the protection of all telephone interests of common concern to members of the association; the protection of subscribers to telephones and exchanges operated by members of this association; the bringing about of a reasonable charge for tolls and rentals of telephones, so that the telephone may be within the reach of the masses of the people; the bringing about of a complete system of municipal communication and long-distance trunk lines within the State of Wisconsin and in connection with independent telephone organizations of neighboring States.

Iowa Telephone Association.

The eighth annual meeting of the Iowa Telephone Association will be held in Des Moines, Iowa, on March 8, 9 and 10. A large attendance is expected. Following is a list of the subjects that will be presented at the meeting: "The Farm Line Proposition," "Operating a Telephone Plant as a Side Line," "Long-Distance Lines," "Jealousy Among Independent Telephone Men," "Shall We Establish a Clearing House?" "Automatic Apparatus from the Standpoint of Service and Operating Expenses," "Our Business Relations," "Leased Toll Lines," "How Can We Promote Better Feeling Among Toll Operators, Inducing Harmony, Improving our Service, and thus Reducing the Lost Call Record?" "Necessity of Uniformity in Toll Line Service and Rates," "Our Loyalty to the Principles of the Association." There will be an exhibition of apparatus and a banquet.

CURRENT NEWS AND NOTES.

WIRELESS TELEGRAPH IN THE WAR.—A London news agency has a dispatch from Rome stating that an Italian officer in charge of a wireless station in Tientsin says the Japanese battleships intercepted "Marconigrams" sent by the Russians.

PARIS METROPOLITAN UNDERGROUND.—The receipts of the Paris Metropolitan railways in 1903 amounted to $3,458,165, against $2,152,335 in 1902, several new lines having been opened during the year. The number of tickets issued was 100,107,631, an increase of 37,984,903 during the year.

LIGHTING BOIS DE BOULOGNE.—One of the most extensive and important pieces of park lighting by electricity is to be carried out in the famous Bois de Boulogne by the municipality of Paris. The park will be divided into three sections and the most popular alleys and avenues in each will be illuminated.

WATER PIPE THAWING.—As already noted in these pages, some little work has been done this hard winter in thawing out frozen water pipes electrically. The latest instance is reported from Elmira, N. Y., where, it is stated, electricians in the employ of the local water company have succeeded in thawing out frozen water mains. A positive wire was inserted at one end of each of a one-hundred-foot section and a negative wire at the other end. The current was then turned on and the ice rapidly melted. The mains were six inches in diameter and located in the outlying portions of the city.

LETTER TO THE EDITORS.

Theories in Wireless Telegraphy.

To the Editors of Electrical World and Engineer:

SIRS:—This discussion on the theories in wireless telegraphy is rapidly becoming "space-expanding," and I am afraid, correspondingly tedious. The main point now at issue, however, is at last well-defined. From Prof. Fessenden's letter in your number of January 30, it is clear that he holds to the idea of space-propagated waves, while my theory involves surface-propagation.

For the present we will agree to differ on this point, though there are many effects on which it would be interesting to have further information as to Prof. Fessenden's conceptions of the wave formation after it has been distorted in various ways. What, for instance, are the successive changes in the electromagnetic field associated with waves transmitted from England to the Antipodes? For I gather that Prof. Fessenden, like myself, believes in the possibility of communicating between antipodal stations.

The question of quantitative measurements of a kind intended to prove whether the law of inverse squares or inverse distances holds is a very complex one, and if any reliable investigations of this matter have been made it would be very interesting to know exactly under what conditions the tests were made, what readings were actually obtained, what the character of the surfaces over which waves were propagated, and how the calculations were made from the readings. I am not aware of any published results bearing on this point. Those who have attempted quantitative measurements in wireless telegraphy must be aware of many of the considerations which would enter into the question, and how anything like accurate allowances can be made for these in working out the calculations is difficult to see. To take one factor only—how would resistance losses due to imperfect and possibly varying conductivity of the surface, be eliminated? Or does Prof. Fessenden contend that there are no losses of the kind, seeing that he holds there are no currents in the surface of the earth with consequently no C^2R losses?

I do not propose to reply *in extenso* to the letter referred to, but rather to revert to the original point at issue, which is in danger, like Prof. Fessenden's sliding wave theory, of sliding out of sight. In its latest aspect the theory appears to belong to M. Blondel.

Can Prof. Fessenden point out any statements made by him in the published account of what he calls "his theory" appearing in the *Transactions* of the American Institute of Electrical Engineers for November, 1899 (which he refers to in his letter in your issue of October 31 last as the first publication of his sliding wave theory), which differ from mine advanced in May, 1899? I fail to find a single point of difference. I do not say that he did not have the space-propagation idea in mind, but that it is certainly not so expressed, and that, therefore, I am justified in my statement that the theory was first given by me.

Some of Prof. Fessenden's arguments (?) in your issue of January 30 in support of his contentions are distinctly humorous: but, I should think, hardly calculated to throw dust in the eyes of any who may care to follow this discussion closely. I refer more particularly to his remarks on "Lodge Waves" and his "discovery" of a new type of wave.

It is to be hoped that Prof. Fessenden will find time to publish a full account of his many valuable researches in wireless telegraphy, and if these are convincing proof of the correctness of his main views, I shall be the first to acknowledge it: but meanwhile I am content to let the case await further experimental developments, and do not abate my position one iota.

London, England. J. E. Taylor.

DIGEST OF CURRENT ELECTRICAL LITERATURE.

Dynamos, Motors and Transformers.

Direct-Current Dynamo Design.—Fynn.—Continuations of his illustrated serial. In the present installment he discusses several details of construction of the armature and field coils and makes the following remarks on commutation. The view is still extensively held that in order to obtain perfect commutation, it is necessary to work the teeth and air-gap distances up to very high values. As a matter of fact, the only effect of such a design on the no-load zone commutation is that it goes a long way to prevent an abnormal distortion of the field which might interfere with the commutation, but provided this distortion is guarded against in some other way the air and tooth densities may be as slow as desired without interfering with perfect commutation. Since the commutation depends on the correct variation with time of the intensity of the short-circuit current, the duration of the short-circuit must play an important part in the process, and all those various e.m.f's or differences of potential which prevail during the short-circuit must be taken into consideration. Further, the nature, intensity and variation of the field through which the short-circuited spool travels must be considered. In order to make commutation possible within the no-load zone, with fixed brushes, it is necessary to so choose these various values that the alteration of the commutating field with a varying load does not alter the short-circuit current sufficiently to produce a materially increased or decreased current density under the brush at the end of the commutation. To obtain a very wide range, it will, therefore, be best to so arrange matters as to obtain a little too great a density at no load, and a little too small a density at full load, the permissible limits of deviation from the normal mainly depending on the quality of the brush used, being considerably greater for carbon than for copper brushes.—Lond. *Elec. Rev.*, January 8, 15, 22.

Eddy Current Losses.—Niethammer.—A mathematical article on the calculation of the eddy current losses in the pole shoes and in the armature. By proper design these losses may always be made so small that they can be neglected. Concerning the losses in pole shoes with slot armatures the rule is that the ratio of breadth of slot to air-gaps should be smaller than one to two. This ratio should be the smaller, the greater the speed and the larger the total pole shoe surfaces. The last point is the reason why many firms (especially American ones) laminate the pole shoes of their large machines. He gives a number of formulas for the eddy current losses in armatures.—*Zeit f. Elek.* (Vienna), January 24.

references.

Theory of Alternators.—Pulsig.—The first part of an illustrated article in which the author shows that the well-known circular diagram, representing the action of induction motors, may be applied to alternating-current generators.—*Zeit. f. Elek.* (Vienna), January 31.

Predetermining Magnet Windings.—Malcolm.—An article on the determination of the value of the current required to bring a coil to the working temperature by assuming that that current would in one hour raise the temperature of the coil one-third of the total rise for ten hours, and making the ten-hour rise the criterion of heating. Thus, if the rise in temperature after ten hours in circuit was to be 60°, the author assumes that the current which produces a rise of 20° in one hour will cause the 60° rise in ten hours. This is not always true, of course, but it is near enough for practical work.—*Am. Elec.*, February.

Lights and Lighting.

Permeability of Fog for Light Rays of Different Wave Lengths.—Rudolph.—An account of experiments made in the laboratory in which he found that artificial fog was more permeable for blue rays than for red rays, which is in disagreement with generally accepted assumptions. His fog was of the density 50, i. e., of 50 candles of a source of light only 1 passed through 1 meter thickness of fog; this is, however, not a dense fog (Editorialle). The results cannot have a general value, but depend on the conditions of the experiment. The absorption maximum depends on the size of the drops of fog.—*Phys. Zeit.*, January 15.

Power.

Electric Hoisting Without Loss of Energy in a Rheostat.—Kammerer.—An illustrated description of an electric hoisting system without the use of a rheostat. The peculiar feature of a hoisting operation is that after a starting period of, say, 20 to 30 seconds immediately a breaking period of 10 to 20 seconds follows. The machine is a combination of two shunt motors designed in such a way that by varying the field strength the number of revolutions of each motor can be varied in the ratio of 2 to 3. The pole wheel of the first motor is stationary, that of the second motor can revolve, while the armatures of the two motors are so connected as to revolve together. The two fields may first be equally excited, but in reverse sense; then the armature of the first motor revolves with a certain speed and takes the armature of the second motor along. The pole wheel of the second motor tends to revolve in the opposite direction with the difference of the speeds of the two armatures with respect to their fields. The pole wheel of the second motor will, therefore, remain at rest as long as the excitation of both fields is equal. If, now, the excitation of the first motor is diminished, while that of the second motor is kept constant, the relative speed of the first armature with respect to the first pole wheel increases and the relative speed of the second armature with respect to the second pole wheel decreases. Hence, the second pole wheel will now revolve in space, the first machine working as motor, the second as generator. The first field strength may be so far diminished that the relative speed of the first armature with respect to its field is 50 per cent. above the normal speed; the second pole wheel will, therefore, revolve with one-half the normal speed. To decrease the latter speed again, it is only necessary to increase again the first field excitation. When it is again normal, the second pole wheel is at rest. When the second (movable) field is then decreased, the second pole wheel will begin to revolve in the opposite direction, the first machine now acting as generator and the second as motor; the operation, therefore, corresponds now to an electric brake. It will be seen that the control is very simple, the exciting currents only being varied; after operation has begun, nothing is changed any more in the connections between the armatures and the supply network. The author thinks that this system would be specially suitable for elevators in office buildings and hotels, running at a speed of 1 to 2 meters per second. —*Elek. Bahnen*, January, No. 1.

Electromechanical Coupling.—Gasnier.—A note presented to the French Academy on an "electromechanical" coupling which allows a continuous change of speed from zero to maximum speed, and which is specially suitable when the prime-mover is near the axle to be driven. It consists of a combination of the prime-mover with two dynamos, one running as generator, the other as motor, and both being of a much smaller capacity than the prime-mover, say 1/3 or 1/4. The prime-mover transmits always a certain part of its power directly to the main axle to be driven, while the rest of its power is absorbed by the electrical machine which runs as generator. A train of epicyclic gearing is used in such a way that the main axle is acted upon simultaneously by both the prime-mover and the dynamo which runs as motor. These two machines are separate and may consequently have different speeds. For instance, an epicyclic gearing may be composed of a central toothed wheel and an external wheel with inside teeth, with teethed wheels between the two. The axles of the latter are fixed on a support. The desired result is obtained by connecting each of the three parts (internal wheel, external wheel and support of the middle wheels) with one of the three axles—that of the prime-mover, that of the electric motor and the main shaft, respectively.—*L'Ind. Elec.*, January 25.

Electric Installation in a French Cotton Mill.—An illustrated description of the installation of the Mirecourt Cotton Mill, which is one of the most important mills in France. Electric equipment was preferred to the ordinary mechanical equipment because the tenders showed that the first cost and the cost of up-keep would be smaller and the efficiency higher in the former case. There is a steam-driven 600-hp alternator giving three-phase currents with a frequency of 50 cycles at 400 volts. The motors receive directly the three-phase currents at 400 volts, but the lamps are arranged so that each receives 230 volts. The motors are of the induction type with short-circuited rotor. All the motors for spinning are placed in recesses in the walls to avoid blocking up the passages. The switches and circuit-breakers are placed in iron boxes. For the weaving shed the motor used for the preparing machines is placed in the wall, and the motors which work the looms are suspended from the ceiling; thus no space has been lost. The pulleys for the above-mentioned motors are divided into two parts by a projecting disc, and they drive by means of two belts, one on each side of the disc, the shafts for two lines of looms; this method annuls the sideway pull of the belt and diminishes the friction on the bearings. The switches are controlled by means of levers from the floor level. For starting the installation the alternator is excited by a battery before starting the engine. All the switches are closed, and the alternator is slowly run up. All the motors start at once and accelerate as the engine runs faster. When this is up to full speed the whole factory is in normal running order. The excitation is regulated at the switchboard to give the desired voltage and the battery is replaced by an exciter. Induction motors are believed to be peculiarly adapted to the special conditions existing in the textile industries, in which speeds are required as constant and uniform as possible under varying loads, with continuous working and facility of control. With a working day of 10 hours and a consumption of 1.7 pounds of coal per indicated hp-hour, the electrical system has saved 836 pounds of coal per day, so that for a year of 300 working days and an average price of $6 per ton, a yearly saving of $680 is effected. This system has been in use for about a year, and the cost of maintenance has been found to be practically nothing.—Lond. *Elec. Rev.*, January 15.

Hydroelectric Developments in France.—BLOCH.—A fully-illustrated article on hydroelectric plants in the country around Grenoble, which was the headquarters of the Congress of Houille Blanche (white coal, meaning the utilization of water falls for producing power). The equipment of the different plants is described and the following figures are given for the utilization of hydroelectric power in the Alpine region: aluminum works, 22,536 hp; other metallurgical factories, 20,485 hp; chlorate of potassium works, 9,000 hp; calcium carbide works, 104,466 hp; sodium chlorate works, 13,500 hp; transmission of power and lighting, 48,727 hp; various industries (like paper and pulp mills, cement works, etc.), 19,989 hp; total, 238,703 hp. (A description of one of the Grenoble plants was printed in these columns February 6.)—Lond. *Elec. Rev.*, January 22.

Coal Consumption in Central Stations.—GILES.—A paper read before the Manchester Section of the (British) Institute of Electrical Engineers, concerning the question of handling coal. He says that if the central station is a small one, burning say 50 tons per week, mechanical stokers will show very little gain over hand-firing, unless it is necessary to avoid all smoke or to burn a very small, low-class fuel. In large central stations, however, mechanical stokers are very satisfactory, for not only can a cheaper coal be used than with hand-firing, but the economy of labor in employing these machines, in conjunction with a coal-elevating and conveying plant, may reach sometimes 30 to 40 per cent. over hand-firing. Kennedy considers the following figures ideal for a central station: 10½ pounds of water evaporated per pound of coal, and 8½ pounds of steam at engine per pound of fuel burned. On this basis the author calculates the coal consumption of a modern 775-kw plant, with the following guarantees: Steam pressure at engine, 170 pounds; steam consumption per kw-hour (full load), 21.92 pounds; vacuum, 24 inches; temperature of steam at engine, 450° F. Then the coal consumption will be 2.58 pounds per kw-hour. He gives a list of coal consumption in various British central stations, with indications of the conditions under which the stations are worked. In this list the coal consumption in pounds per kilowatt-hour is highest for Blackpool, 15.4; and Derby, 13.2; and smallest in Bradford, 4.1; Salford, 4.3, and St. Helens, 5. The load factor in these stations is 14.32, 13.36, 20.93, 21.84, and 19.78 per cent., respectively. The influence of the load factor on the load consumption is also shown in diagrams.—Lond. *Elec.*, January 22.

REFERENCES.

Electric Power in Railway Workshops.—DUB AND SUCHY.—An illustrated description of the electric equipment of the railway workshop of Linz in Austria. There are 25 three-phase induction motors used for operating cranes, pumps and drills. With the exception of two, which have a short-circuited armature, all the motors are provided with slip rings. Power is provided by a three-phase generator running at 110 revolutions, and giving 200 kilovolt-amp. for non-inductive load, the voltage being 220.—*Elek. Zeit.*, February 4.

Electricity in British Coal Mines.—A note stating that electrically-driven coal-cutting machines have come largely into use in Lancashire, where experiments have been going on since 1899, with great success. The output per man has been increased and coal is now economically worked which previously had been unworkable at a profit by hand.—Lond. *Elec. Rev.*, January 22.

Turbines.—SCHMIDT.—A long article on the principles and theories underlying the construction of vapor turbines. The theoretical formulæ of mechanics and thermo-dynamics are given, upon which investigations with regard to the turbine must be based in order to obtain useful and reliable results. By means of the formulæ given, the nozzle area and proportions, as well as the bucket velocity, may be predetermined with sufficient accuracy for all practical purposes.—*Am. Elec.*, February.

TRACTION.

Electric Traction on Trunk Railways.—HERZOG.—A profusely-illustrated article in which the author first emphasizes that if ever electric traction is to be introduced on trunk railways, it must be done without any interruption of service, and on the tracks and rolling material, now available, with the exception of the locomotives. The weakest point in electric traction will be the trolley line. The author describes in detail the system of the Oerlikon Company (single-phase transmission, motor-generators on the locomotive, direct-current motors) and dwells at length on mechanical details of construction of the trolley and trolley wire (which, of course, may also be used on locomotives equipped with single-phase motors). The trolley wire is not above the center of the road, but at the side, and the current is taken off by means of a rod curved in a convex form towards the trolley wire and pressed against the latter by means of a spring. This rod is movable in a plane perpendicular to the direction of the train, around a shaft which is placed insulated on the locomotive. Moreover, the position of this rod may be varied in height or in cross-direction either by hand or automatically. The advantages are that the rod adjusts itself to any position of the trolley wire. The current is generally taken from the upper part of the trolley wire, where there is no ice or sleet in winter. The fact that the trolley wire is placed at the side of the road will enable the introduction of the system without interruption of the steam service.—*Elek. Bahnen*, January, No. 1, 2.

Conduit System.—MILLAR.—An abstract of a paper read before the (British) Institute of Civil Engineers, on the electrical reconstruction of the South London tramways on the conduit system. The conduits are 2 ft. deep by 1 ft. 2½ in. wide, and consist chiefly of cement, concrete and cast-iron yokes, the latter spaced at 3 ft. 9 in. intervals, which support the slot rails and form a template to which the concrete panels are moulded. Chambers are formed at intervals of 5 yards for the reception of the insulated supports from which the T-shaped conductor bars supplying current to the cars are hung. These insulators have a porcelain body in appearance like an inverted jar and are protected and secured in an iron cap, which is bolted to the slot rails. The steel rod which carries the conductor bars is cemented inside the porcelain cup, and the actual attachment to the bars is made by means of cast-iron clips, capable of adjustment by means of an eccentric washer. The conductor bars have a sectional area of 2.15 sq. in. They are placed symmetrically in the conduit 6 in. apart, and the minimum air-gap between the conductors and the conduit structure is 2 in. Drainage of the conduit is provided for by connecting it to the sewers at intervals of 60 yards. The slot is ¾ in. wide. The line is divided into ½-mile electrical sections, each section being fed by separate distributors. The current is generated by two 1,500-kw, direct-current sets, the normal voltage at the main station being 625 and on the line approximately 550.—Lond. *Elec.*, January 15.

Electric Traction in Great Britain.—A table giving a large amount of statistical information on the present condition of electric traction in Great Britain; also an editorial on this subject. The number of electric tramways supplied from combined tramways and traction stations is no less than 88 out of a total of 130; that is, over ⅔ of the whole list. Central station engineers endeavor to improve the load factor by adding a tramway load and in some cases an extremely low price is charged for the tramway supply. On the other hand, while public lighting is a useful addition to a tramway station, the peaky private lighting is not. Four electric railways were running at the end of 1902 in Great Britain: the Liverpool Overhead Railway, the City & South London Railway, the Waterloo & City Railway, and the Central London Railway. During 1903 two new lines were opened: the Mersey Railway, and the pioneer, six miles of electrically-equipped Metropolitan District Railway. Shortly the Great Northern & City Railway and electrically-equipped sections of the Northeastern, Lancashire & Yorkshire Railway will be opened. Progress is also being made with the transformation of the Metropolitan District Railway and the building of the tube lines of the Yerkes group. In electric railway, as in tramway work, standardization is now being approached. The main difference between electric railway systems lies in the position of the third rail and as to whether an insulated fourth rail is employed as return conductor. A third rail in the center of the track is unsuitable for heavy railways on account of a low-load gauge and the possibility of pending chains, etc., coming into contact with the rail. Thus the construction, adopted in the four older lines, with the positive conductor rail between the tracks, has been abandoned. The Lancashire & Yorkshire Company has laid an insulated fourth rail as negative conductor between the tracks.—Lond. *Elec.*, January 29.

Trolley Head.—An illustrated description of a trolley head designed to lessen the difficulties of replacing the trolley on the trolley wire, when it has jumped off. It consists of a swivel head of the usual type in most respects, but with the addition of two horns, one on either side of the wheel, which can be elevated for use in replacing the trolley on the wire, and afterwards return to their normal position, housed in the metal ball surrounding the wheel. The horns are actuated by a cord which is carried down to the conductor's platform and which, when pulled, causes the horns to be raised by means of gearing in the trolley head. The reverse motion is brought about by a spring in the head.—Lond. *Elec. Rev.*, January 8.

Trolley Ears.—An illustrated description of a device of an English company to prevent the flashing and hammering at trolley ears, which is due to the fact that the line is swollen out by the overlapping of the ear. This protuberance forces the trolley head down causing it to jam and producing an arc. To prevent this the wire, instead of going straight through, as is usual, is curved upwards for a few inches of its length. The wire is held in position by two plates suitably grooved and bolted together. By this means the ear does not protrude beyond the wire. It is said that experiments have shown the device to be satisfactory.—Lond. *Elec. Rev.*, January 15.

Single-Phase Traction.—EICHBERG.—An article illustrated by diagrams in which he first explains some characteristic feature of the Winter-Eichberg motor and then compares it with the Finzi motor, the comparison being in favor of the former especially with regard to efficiency, and power factor, and also weight.—*Elek. Bahnen*, January.

Paris.—PAUL.—An illustrated description of the generating station and conduit system of the General Parisian Tramways Company. The system differs radically from American practice, the chief difference being in the employment, over part of the road, of side conduit which also serves as one of the rails. The slot is rather wide, and at switches it is diverted from the side of the track to the center. As the trolley system is also used, provision is made for removing the plow at certain points.—*Am. Elec.*, February.

Car for Measurements.—BJOERKEGREN.—A fully illustrated description of the equipment of a special car with measuring instruments in order to determine the energy consumption, etc., on the Berlin tramways.—*Elek. Zeit.*, January 28.

INSTALLATIONS, SYSTEMS AND APPLIANCES.

Three-Phase Working.—BREW.—The first and second parts of an illustrated paper, read before the Dublin Section of the (British) Institute of Electrical Engineers, on three-phase working, with special reference to the Dublin system. In this city the change-over of the supply from the 2,000-volt, 83-period, single-phase station at Fleet Street, to the 5,000-volt, 50-period, three-phase station at the Pigeon House, situated over three miles distant, could be comfortably effected in something like 20 seconds, whereas the arrangements for accomplishing this result had been maturing for something over two years. There are two 1,000-kw and two 500-kw alternators, giving 5,000-volt, three-phase currents. Since the new station is very near the sea, troubles had been prophesied on account of the direct generation of high-tension currents in the alternators; but the latter have been working continuously for seven months without giving any indication that the sea air disagreed with them. Some data are given on the design, self-induction and capacity of the transmission mains, and the relative advantages are discussed of the use of single-phase and three-phase transformers and delta or star connection in sub-stations. He mentions that in Dublin they had not the slightest difficulty as regards the banking of single-phase transformers in delta or star connection, transformers of 25-kw output sharing the load proportionately throughout the range with transformers of 250-kw output when banked with them delta and star-connected. Between the generating stations at Pigeon House and the central distributing station at Fleet Street, a distance of 3.1 miles, three trunk mains have been laid, each consisting of a three-core, lead-covered paper cable, the section of each core being 0.15 sq. in. The smaller sizes of Dublin sub-stations are connected with the central distributing station by 0.04 sq. in., three-core sub-feeder and spare. The paper is to be concluded.—Lond. *Elec.*, January 22 and February 5.

An Emergency Switch for Central Stations.—THORNTON.—An illustrated article in which the author points out that most modern generating stations for the supply of electrical energy in bulk have one weak spot. In the event of an arc developing at the main bus-bars, it cannot, as a rule, be quickly extinguished without either danger to the attendants or damage to the machines. In some cases it has been necessary, in order to save the board and leads, to break the main exciting circuit. Instead of this the author makes the suggestion that an auxiliary switch should be fitted to the bus-bars from which the generators are excited, so that by this switch all the fields, instead of being broken, can be simultaneously short-circuited. Such a device enables the station to be shut down without shock to any part of the system, the magnetization taking a few seconds to diminish until the voltage required to maintain the arc cannot be generated. As the arc ceases and the bars are cleared, all but one of the main switches can be opened, the field circuit restored and supply re-established.—Lond. *Elec.*, January 15.

Protecting Devices for Generators.—CLOTHIER.—A discussion of the probable cause of the recent fire in the Bristol Central Station and its lessons. As protecting devices for generators he thinks that fuses are bad, since among other well-known reasons the sound machines are likely to be isolated at the wrong time. A really reliable device that would automatically open the generator switches on the reversal of current has long been sought for, but it has been found that while such devices meet the requirements for high-resistance faults, yet in case of low-resistance faults (short-circuit on the armature, etc.), the low potential difference across the shunt coil, on alternating-current systems, renders this apparatus inoperative and useless just at the time when reliability and certainty in action are most essential. He thinks it is better to do without automatic protection and to risk injuring the alternator rather than to cause a complete or even partial cessation of the supply to the consumers. By removing the fuse from existing generator panels, space will be available for the addition of a reverse-current indicator, which, by the glow of green and red lamps, respectively, will show whether the alternator is generating or taking current from the bus-bars. For the barest necessities it is proposed to arrange on the switchboard platform, or at any other convenient place, at least 20 ft. away from the permanent switch gear, a system including an arrangement of connections and switch boxes, one of these boxes being provided for each alternator installed. Each feeder has also a place in one or more of these boxes, the connections being arranged so that each machine can be run independently upon a group of feeders, the number of which will vary according to the size of the machine and feeders. Then in the event of a breakdown placing the entire switch gear out of commission the switch can be rapidly reinstated by the independent running of all machines for the time being on the several groups of feeders which are respectively connected up solid. Arrangements are also made so that, in the event of any single machine being out of commission, the feeders, which were allocated to that machine, may be coupled up to the other generators. The supply pressure may be regulated on the engine stop valve and governor, and indicated by a pair of lamps connected in parallel between the earth terminal and the tapping from alternator armature. The system affords a ready means of isolating for cleaning and other purposes, besides forearming against the complete or partial displacement of the permanent switch gear or connections inside the electric works.—Lond. *Elec. Rev.*, January 15.

English Central Station.—An illustrated description of the municipal plant of Swindon, which is a town of 48,000 inhabitants, in the west of England. The three-wire, direct-current system is used. There are three 200-kw dynamos, with compound winding for traction supply. The series winding is so arranged that the main current can be diverted as required through a shunt and the compounding effect thus varied at will from zero to overcompounding. A balancer is provided capable of dealing with 100 amp. on the middle wire; it can automatically regulate with a load of 50 amp., thrown on either side; a motor-generator is installed comprising a motor in the center with a generator on each side. The motor is of 42 hp and the generators are wound for 220 to 310 volts. It is used for charging the accumulators and for taking current from the three-wire switchboard and supplying it to the tramway board. In the latter case the two outer machines are connected across the three-wire system, and the center one across the tramway bus-bars, so that with this arrangement, one dynamo may be used to supply both lighting and heating. The battery consists of 252 cells with a capacity of 350 amp.-hours. Besides lighting, current is used for motor driving in various factories.—Lond. *Elec. Rev.*, January 15.

Electro-Chemistry and Batteries.

Edison Storage Battery.—A full account of the discussion following Hibbert's paper on the Edison battery. Hibbert, Fleming, Wade, Joly, Cooper and Patchell participated in the discussion. The tests made independently by Janet, Hospitalier, Finzi, Hibbert and Fleming gave practically the same results. Fleming had ascertained by special experiments that there is no local action between the active material and the support; that the active materials used by Edison are insoluble in the caustic potash solution, and that the active material was brought out of the pockets by heavy discharges only to an extremely small extent; while with respect to weight and capacity the Edison battery is not greatly superior to light lead cell, it is so with respect to durability. Joly gave curves on the charging of the battery. In an editorial on the subject it is said concerning the battery "that, although it is not in the least likely to effect a revolution in accumulator traction, there does not remain a shadow of doubt that it has many features which are superior to those possessed by the lead cell. Provided the price is not excessive, the outlook is bright."—Lond. *Elec.*, February 5.

REFERENCE.

Rare Elements.—Lenher.—The conclusion of his article on the properties and commercial applications of rare elements. He first deals with the rare earths and their use in the incandescent gas mantle; vanadium and uranium and their application in special steels; columbium and tantalum, selenium and its behavior when lighted; tellurium; molybdenum and tungsten, and the platinum metals.—*Electrochem. Ind.*, February.

Units, Measurements and Instruments.

Potentiometer.—Fisher.—A description of an improved form of potentiometer which is shown in Fig. 1. The general principle is well known, a storage cell, E, supplying constant fall of potential over $A B C$, where $A B$ is a slide wire and $B C$ a given number of sections of wire, each equivalent in resistance to $A B$. The potential, F, to be measured is connected in series with galvanometer G to the

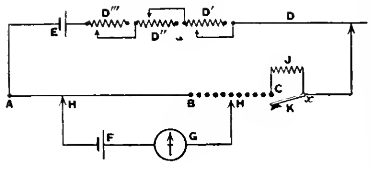

FIG. 1.—POTENTIOMETER.

sliding contacts, $H H$. Among the new features is the use of resistance D, D', D'', D''', of which D is a straight wire, similar to $A B$, and carrying a suitable scale, definitely calibrated in known terms, $A B$ as unit. D', D'', D''' are rheostats, duly calibrated in terms of D and so graded that D' consists of 10 coils each of the same resistance as D. D'' consists of 10 coils each equal to D' in the aggregate, and D''' bears the same ratio to D''. So there are practically two potentiometers, $A C$ and $D D'''$ in series, calibrated and of known value in absolute terms throughout. Another new feature is the coil J, capable of being short-circuited by the key K and having a potential stud, X, with which, when necessary, H can make contact. Preferably, this coil is made nine times the ohmic value of $A C$. The following advantages are claimed for this instrument. It is self-checking for accuracy throughout its range without the necessity of the use of auxiliary apparatus, alteration of, or addition to, connections in use. It possesses means of compensation for any known errors in standards, by which the same are made direct-reading and subsequent corrections eliminated. Higher potentials than at present may be compared direct on the instrument without the use of a volt or a ratio box. The working potential of the instrument may, after standardization, be altered to any value without restandardization, and yet its altered value over any portion of the working part be definitely known. Considerable saving is effected in the cost of necessary additional apparatus, especially in the measurement of current. Greater accuracy is obtained in the measurement of small potentials and in the comparisons for ohmic value of standard resistances. Indefinite prolongation of the lower portion of the scale is possible, enabling thermo-junction temperature measurements to be taken with greater ease and accuracy. Indefinite prolongation of the whole scale is possible with consequently greater range. The whole instrument is alive for measurements, with no dead portion, as in the older form of apparatus. The various applications are described in detail.—Lond. *Elec.*, January 15.

Frequency Measurements.—Hartmann - Kempf.—An illustrated article in which he gives an account of careful measurements of the exactness of his instruments for measuring frequency. The principle is to subject small pieces of sheet steel or steel "tongues" (as used in some musical instruments) to the influence of an electromagnet, which is excited by the current, the frequency of which is to be measured. There is provided a series of such steel tongues of differ-

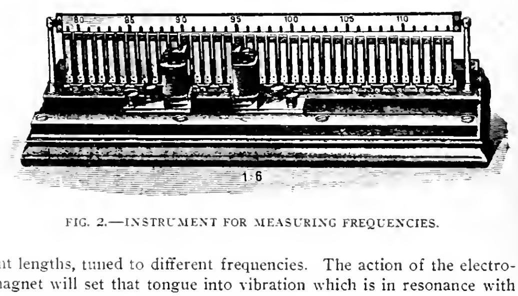

FIG. 2.—INSTRUMENT FOR MEASURING FREQUENCIES.

ent lengths, tuned to different frequencies. The action of the electromagnet will set that tongue into vibration which is in resonance with the frequency of the exciting current. The vibrations of the tongue may be observed either by the eye or by the ear. An instrument of the latter kind is shown in Fig. 2. He found that the wave form of the exciting current or the value of its amplitude did not materially change the result. The applications of the instrument to measurements of the variation of the frequency to the connection of alternators in parallel and to the determination of the speed of the prime-mover are discussed.—*Elek. Zeit.*, January 21.

REFERENCES.

Calibrating Electrometers.—Harms.—While endeavoring to measure the smallest currents through gases in absolute units, he found that it was impossible to determine the capacity of electrometers with sufficient exactness, since the capacity depends to a great extent on the configuration of bodies nearby. He, therefore, did not determine the capacity of a condenser (which, he believes, is a hopeless attempt with the usual methods for capacities below 100 cm.), but measured the induction of one condenser plate on the other by two independent methods. His method is specially suitable for calibrating quadrant electrometers and for determining the capacity of measuring instruments for atmospheric electricity.—*Phys. Zeit.*, January 15.

Flicker Photometry.—Simmance.—A paper in which the author explains the principles of the flicker photometer, as discovered by Root, and describes the Simmance-Abady photometer, which was recently noticed in the Digest.—*Progr. Age*, February 1.

Telegraphy, Telephony and Signals.

Tone Test.—O'Brien.—An illustrated article on the tone test as applied to calls completed over long distances and toll lines. Since the adoption of the multiple switchboard in telephone central offices, it has been necessary that some means should be provided whereby the condition of any line connected to the switchboard might be ascertained by any operator. With the advent of the common-battery system it became possible not only to expedite the work of an operator, but also to give to the operators at the switchboard the means of obtaining a more intimate knowledge of the conditions of the connected lines than had heretofore been possible. This end has been very largely accomplished through the use of distinctive test circuits, in which an interrupted current of a certain periodicity is applied to the sleeve of the line jacks in much the same way as the original "busy" test; the effect of this arrangement being that upon testing the line the operator instead of receiving the usual click, hears through her receiver a musical tone of a character depending upon the periodicity of the interrupted current.—*Am. Elec.*, February.

Tramway Telephone System.—An illustrated description of a system of service telephones used in connection with the Dublin tramways. Six three-core cables leaving the power station and radiating out to the various termini are looped in on the way to about 80 feeder pillars and 13 offices or car depots on the various roads. One of the wires is used for the Board of Trade earth voltage test, but the other two are available for telephone service. While maintaining this simplicity of the open-circuit system with only one ringing battery at the power station, it is possible from the power station to ring up a depot, or, when there are two depots or one pair of wires, to ring up either depot without calling the other. It is possible to put into communication with each other any two outlying depots and for the outlying depots to signal to the power station when they have finished speaking through to another depot.—Lond. *Elec.*, January 29.

Telephone Engineering.—Dommerque.—Another article of his serial dealing specifically with the erection of cables.—*Am. Elec.*, February.

Miscellaneous.

Electrometallurgy of Gold.—A long article on the electrometallurgy of gold in South Africa from 1897 to 1899, with abstracts of papers read before the Chemical and Metallurgical Society of South Africa, with special reference to the question under which conditions electrolytic precipitation is preferable to zinc precipitation. Butters' paper on the Siemens & Halske process on the treatment of slimes is abstracted at length. Other papers dealt with electrode connections for electrolytic vats, the influence of temperature in the cyanide process, and the application of the theory of ions to the electrometallurgy of gold, and a long discussion of the relative disadvantages and advantages of zinc and electrolytic precipitation.—*Electrochem. Ind.*, February.

Conductivity of Solutions in Alcohol.—Kraus.—First part of a paper on the electrical conductivity of solutions in methyl alcohol in the neighborhood of a critical point. In the present installment the results of measurements are given in form of tables, but conclusions are not yet given. The paper is to be concluded.—*Phys. Rev.*, January.

Microstructure of Metals and Alloys.—Campbell.—An illustrated article in which the author emphasizes that chemical composition should not be considered to be everything, for unless the structure of a metal or alloy is good, the best of materials will not make the finished product anything but a very medium article. Photographs are given of the structure of cast aluminium and electrolytic copper and silver, and Roozenboom's diagrammatical representation of the different alloys of iron and carbon (as function of the per cent. of carbon and of the temperature) is given together with various photographs of the structure of the various alloys.—*Electrochem. Ind.*, February.

New Books.

Elektrische Apparate für Starkstrom. By Georg J. Erlacher. Hannover: Gebruder Janecke. 228 pages, 131 illustrations. Price, 8 marks.

This volume written by a specialist on the subject is devoted entirely to switches, fuses, circuit-breakers, rheostats and, incidentally, switchboards.

Its author thinks that too little is known about these articles, they being considered as side shows by the majority of designing engineers and their manufacture, hence left to empirics. He has, therefore, endeavored to make a critical analysis of the subjects and to deduce from experiments and by calculation trustworthy data to guide others in the same field. While it can hardly be said that he has succeeded in producing a switch, circuit-breaker, fuse and rheostat maker's *vade mecum* to which all will turn, there is no doubt that the book is well worth perusal, and that the reader will profit thereby.

The opening chapter, on switches, after discussing the various forms of contacts, gives tables showing the current density, pressure per square cm., resistance and other data of contacts between flat blades and spring clips of the kind often used in this country and of two forms of the laminated brush contacts extensively employed abroad and beginning to find favor on this side for heavy current work. The tables were made from experiments, and from them are deduced rules for designers. Numerous makes of switches are illustrated.

The high-tension switch section that immediately follows is interesting to the American designer chiefly because of the descriptions of the air blow-out switches made after the pattern of the Siemens & Halske "horn" lightning arresters, of which we have often read, and which seems as sound in principle as it is simple in construction, but of which the reviewer at least has seen no examples in this country. The entire omission of oil break and distant control switches, however, seems strange.

In the chapter on fuses there are sets of curves giving the interrelation of melting points with fuse wire lengths and the mass of the terminals together with curves showing the time required for rupture with different currents. Of commercial forms of open-type fuse blocks, but few are shown and only one make of the enclosed fuses, which are justly so popular here is illustrated, even that one receiving but scant attention. The circuit-breaker section is handled much as the switches were, the major attention being given to two undeniably ingenious types made by Schuckert & Co. and the Society Ind. Telephones, respectively.

Thirty pages are next given over to end cell switches and form an acceptable addition to the exceedingly meagre literature on that subject. The illustrations and detail drawings of heavy current apparatus of this kind are particularly good.

In rheostats the author pins his faith to the form in which resistance wires of nickelin are wound on hollow grooved porcelain spools, the latter being mounted in suitable iron frames. Leads tapped off from the wires run through holes in the side of the spools into their hollow interior and then to the usual contact segments.

Apparently the overload and underload release attachments, whose presence is compulsory here, are not very popular abroad, as but one non-American rheostat so equipped is illustrated. There are, however, numerous types of which we seldom see examples, notably rheostats in which the moving arm is actuated by a screw mechanism to prevent the possibility of starting motors with their aid too fast, and rheostats for use with multiphase motors. There are also some interesting examples of reversing rheostats for the control of crane motors and the like.

As the switchboard section occupies less than a dozen pages of printed matter it may be surmised that it is not very exhaustive. There are a few constructive details in it that are mildly interesting, a few tables of no particular moment and three insipid diagrammatic views of typical switchboards. The volume has its place in a designer's library.

Plans of the Allis-Chalmers Company.

A few weeks ago we gave an outline of the plans of the Allis-Chalmers Company in regard to entering the electrical field, etc. We have now received the following official announcement, signed by Mr. W. J. Chalmers, vice-president:

We beg to notify you that our company has widened its scope of manufacture, and engaged in most important industries. We could not give you the information at an earlier date, as we have only just concluded final arrangements for all the new industries we are to engage in, which we are pleased to enumerate as below: steam turbines, hydraulic machinery, gas engines and electrical machinery.

As regards steam turbines, we have become associated with and form part of the Steam Turbine Advisory Syndicate of England, which is composed of Yarrow Shipbuilding Company, of England; Tweedie (Vulcan) Shipbuilding Company, of England; Willans & Robinson, engineers and well-known engine builders, of England; Mr. Fullager, formerly chief engineer Parsons Steam Turbine Company, of England, now consulting engineer for Steam Turbine Advisory Syndicate, and Allis-Chalmers Co.

Our turbine is of the horizontal type, which is the type Parsons, of England, and Brown, Boveri, of Switzerland, manufacture. We are convinced after an investigation by our engineering staff in Europe and elsewhere extending over a period of two years, that we have a steam turbine that is at least in efficiency and economy equal to the best make of Parsons or Curtis, which are the types most known. We are now prepared to enter into the building of steam turbines of the following sizes: 500, 750, 1,000, 1,500 and 5,000 kw and can, if required, build up to units of 10,000 kw. The largest size that has ever been built of any type of turbine is 5,000 kw. Our license from the Advisory Turbine Syndicate concedes to us all of the United States, Canada and Mexico, with equal rights and privileges in South America, and rights to do business elsewhere in the Western Hemisphere.

We have concluded arrangements with Escher-Wyss & Co., of Zurich, Switzerland, whereby we become the sole licensees for the Western Hemisphere of their famous hydraulic machinery, several types of which have been installed at the Niagara Falls plant of the Cataract Construction Company, aggregating 85,000 hp. Escher-Wyss & Co. have long enjoyed, and still enjoy the reputation of being the best-known manufacturers of turbines in the world. We only mention Niagara Falls as one of the plants employing thousands of horse power installed by Escher-Wyss & Co.

We have bought the American patents, and have become sole licensees for the Western Hemisphere of the Nurnberg Machine Company, Nurnberg, Germany, for their gas engines, and are now prepared to make gas engines up to any required horse power. At the present time we are prepared to build gas engines from 250 to 1,500 hp. These engines are suitable for consumer gas or taking the waste gas from blast furnaces and utilizing same with economy and efficiency. It is in the blast furnace trade that we expect the largest business to result. The engine is not an experiment, but engines of 1,500 hp are now in operation in Germany, and it was after two years' investigation by our engineering staff of the various gas engines, that we selected the Nurnberg, and have engaged in its manufacture. It is a prime mover, either for blowing engines in blast furnaces, or for direct-connected dynamos in generating electricity, or for any other purpose where power is required.

We have engaged in the manufacture of generators, motors and electrical apparatus in all its branches both for stationary and railroad work, power-house installation for transportation purposes and electric lighting. We have engaged to take charge of this department of our business Mr. John F. Kelly, formerly of the Stanley Electric Co.; Mr. William Stanley, of the same company, as consulting engineer, and Mr. John H. Kelman, formerly superintendent of the Stanley Co., as superintendent of this department. In addition we have engaged others of the late Stanley Co.'s staff whose services we can use, and have drawn a further supply from the best electrical establishments in this country and in Europe; so that we are fitted out with a complete engineering staff in every branch of the electrical business, and we believe that Messrs. Kelly and Stanley are recognized in the profession as standing equal to the best.

From the above you will observe that we have entered the field not only in the line of prime movers, embracing reciprocating engines, in which field we have always led, but also with steam turbines, gas engines and hydraulics; and with electrical apparatus combined with any one of these prime movers we are now prepared to estimate upon and accept contracts for complete plants of all description and furnish the best of their respective kinds.

Motors for Yerkes' London System.

The British Thomson-Houston Company, Limited, of Rugby, England, which concern is controlled by the General Electric Company, of New York, has been awarded the important contracts for the motor equipments to be used on the 140-odd miles of underground and surface electric traction system now being constructed in and around the British metropolis by the Underground Electric Railways Company, Limited, of which Mr. Charles T. Yerkes is chairman. Before the decision was arrived at the "B. T.-H." equipments were subjected to an exhaustive test, extending over a period of 12 months and conducted on the Ealing-Harrow section of the Yerkes lines. Four hundred and eighty cars in all will be equipped, each car having motors aggregating 500 hp in capacity. Each motor will be enclosed in a steel case. The value of the contract exceeds $5,000,000.

Exhibits at the Ohio Independent Telephone Convention.

A number of prominent manufacturers of supplies had exhibits of their lines in the corridors and in the parlors of the Grand Hotel.

The Miller Anchor Company, Norwalk, Ohio, showed its popular anchor and auger for setting anchor. G. H. Miller, president, was in charge.

The Kester Electric Manufacturing Company, Chicago, showed solder and soldering pastes and gave out samples of the goods. J. E. Goodwin was present.

The Creaghead Engineering Company, Cincinnati, displayed a complete line of its construction tools, pole fittings, and overhead equipment. T. J. Creaghead, president, and J. H. Creaghead, secretary, were present.

The Cincinnati Railway Supply Company showed a complete line of its rope clips.

The Stromberg-Carlson Telephone Manufacturing Company, Chicago, showed a line of telephones and apparatus. George H. Fister, Columbus, and R. B. Taylor, Louisville representative, were in charge.

The North Electric Company, Cleveland, had quite a complete line of its telephones and showed numerous parts. Several handsomely illustrated booklets were given out. George B. Pratt was in charge.

The American Electric Telephone Company, Chicago, had a number of its latest selective system lock-out telephones in operation and connected with two magneto boards. It also showed a line of instruments and parts. P. J. Eubanks, of Chicago, was in charge.

The Swedish-American Telephone Company, Chicago, showed two magneto boards and a line of instruments and parts. E. B. Overshiner, president; C. H. Macklin, secretary and general manager, and J. A. Russel, were present.

The Kellogg Switchboard & Supply Company, Chicago, showed a number of instruments and parts. A. R. Kratz, manager of the Cleveland branch, was present.

The Eureka Electric Company, of Chicago, showed instruments and material.

THE MONARCH TELEPHONE MANUFACTURING COMPANY, Chicago, was represented by W. H. Trimm, who showed a line of instruments.

THE WESTERN TELEPHONE MANUFACTURING COMPANY showed a 150-line magneto board and a large line of instruments. J. E. Keelyn, Chicago, was present.

THE STERLING ELECTRIC COMPANY, of La Fayette, Ind., was represented by W. E. Doolittle and Fred E. Freers, who showed a line of instruments.

Among other people present were the following: J. B. Magers, Indianapolis Arm, Bracket & Pin Company, Indianapolis; F. M. Kinnerim, the F. Bissell Company, Toledo; A. E. Barker, the Dean Electric Company, Elyria, Ohio; E. F. Kirkpatrick, the McRoy Clay Works, Chicago; W. P. Bowman, W. W. Affleck and J. W. Brooks, John A. Roebling's Sons Company, Cleveland; F. J. Crook, Automatic Electric Company, Chicago; A. A. Anderson, Standard Underground Cable Company; Samuel W. Gliver, the R. M. Gliver Electric Company, Cincinnati; Ernest J. Paradis, the W. G. Nagle Electric Company, Toledo, Ohio; J. A. Kenney, the American Electric Fuse Company, Chicago; G. W. Sebastian, the Sebastian-Leight Manufacturing Company, Ashland, Ky.; George Chandler, the American Steel & Wire Company, Chicago; E. H. Hammond, American Electrical Works, Chicago; R. B. McMeal, "Telephony," Chicago; L. E. Clark, *American Telephone Journal*, Chicago, and George S. Davis, ELECTRICAL WORLD AND ENGINEER.

Low Voltage Generators.

The subject of the design of large current low-voltage generators (say from one to ten volts) has received comparatively little attention in electrical literature. In what has been published unusually low magnetic densities in the poles have been recommended, but this requirement has been disputed. Mr. Charles J. Bogue, 209 Centre Street, New York, has placed on the market a line of low-voltage machines, views of two of which are shown in Figs. 1 and 2, in which the densities at the pole-shanks range from 20,000 gausses to 23,000 gausses in the larger machines. It is held that the best regulating low-voltage machine is a properly proportioned shunt dynamo having as an essential as large a proportion of the magnetomotive force as possible expended in the portion of the magnetic circuit covered by the field coils.

The section of the steel at the pole-shanks is so reduced that from 50 to 60 per cent. of the field ampere turns are expended in the poles. All of the other parts of the magnetic circuit are so proportioned as to get the smallest amount of reluctance possible. Pole-shoes are made very large, having an area from three to four times as great as the sectional area of the pole shank. The armature slots being as narrow as possible, a thin gap may be used. This, in conjunction with the large area pole-shoes, gives an extremely low gap density.

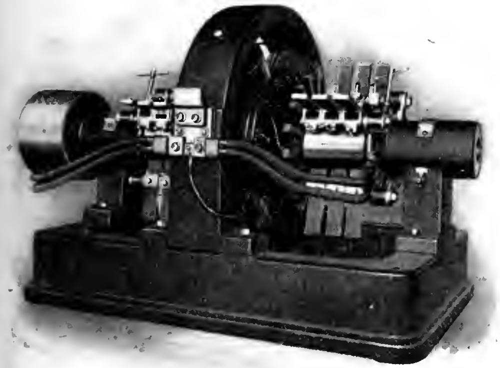

FIG. 1.—LOW-VOLTAGE GENERATOR.

To take the fullest advantage of this low density, special attention has been paid to the exact shaping of the pole-tips so that they shall be over-saturated at their junction with the pole proper. This gives an unusually even density in the gap under all loads, so that all of the line of machines will run from zero load to a heavy overload without any perceptible shifting of the neutral and consequently without sparking.

The armatures are run at a low density (about 6,000 gausses) both to keep down the heating and to take as little of the magnetizing force as possible so as to allow it to concentrate in the poles. The yokes are so proportioned as to have a low saturation, about 3 or 4 per cent. of the field ampere-turns being taken.

The result of the combination of the various features mentioned is a shunt machine which is claimed to regulate on practical work—

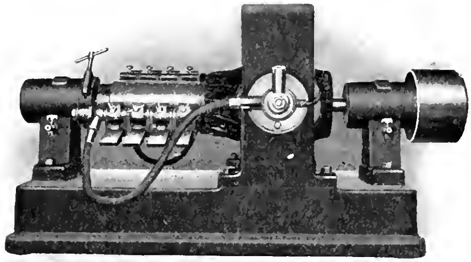

FIG. 2.—LOW-VOLTAGE GENERATOR.

taking into consideration variable brush resistance and variable speed—better than a perfectly compounded machine and better than an ordinary low-density shunt machine.

The mechanical design of these machines is fully up to the most modern requirements, all of the shafts and bearings being large, well fitted and well oiled. The brush-gear has received much thought. While apparently a minor detail, it is really one of the most difficult parts of the entire design. Nice judgment has to be used in this part, for the currents carried are so out of proportion to the size of the machine that the resistance between the commutator and the terminals has to be kept very low. In all sizes of this line of machines the only parts rising more than 40° F. are the commutator and brushes.

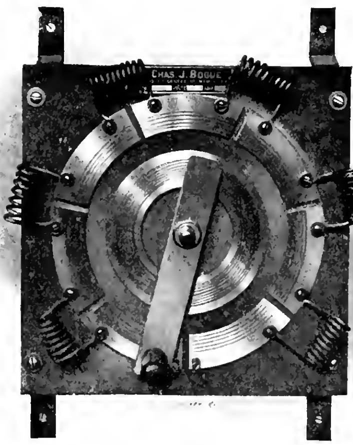

FIG. 3.—FIELD REGULATOR.

While advocating shunt machines for all ordinary work, the maker excludes special cases where it is necessary to keep a perfectly even voltage or to obtain a greater range of regulation than is advisable with a shunt machine. In such cases separate excitation is advised, the fields being wound for either 110 or 220 volts. Five hundred volts is hardly advisable on account of the fact that the greater number of these machines are used in plating or electrotyping establishments, where it is difficult to keep them free from acids, or their fumes, and also from steam, etc.

NEWS OF THE WEEK.

Financial Intelligence.

THE WEEK IN WALL STREET.—Depressing tendencies abroad and comparatively poor railway earnings at home affected prices of stocks unfavorably and restricted activity, and the market was dull and lifeless. The slackness of general trade, due to the severe and protracted winter weather, was also a depressing factor. The United States Steel stocks, on the other hand, were relatively steady, and a good effect has been produced by the placing of large orders for rails by various railway companies. There is an impression on "the street" that better conditions will appear in the iron and steel trades and that liquidation in the United States Steel issues has spent its force. Money continues easy. All of the electric and traction securities were depressed and closed with losses, compared with the prices of the previous week. Of the tractions, Brooklyn Rapid Transit and Metropolitan Street Railway closed with net losses of 2⅜ and 1½, respectively, the last prices being 40⅜ and 141¾. General Electric's closing quotation—163—was the week's lowest, the highest being 167. The net loss was 3 points. Westinghouse closed at 159, being a decline of 1¼ points. Western Union, American Tel. & Tel. and American Tel. & Cable are all down, the losses in the order named being ⅛, 2 and ½, the closing prices being 87, 121 and 84¾, respectively. Commercial Cable closed at 192, this being ½ higher than the last recorded quotation. The curb market for outside securities was irregular, with weakness in Brooklyn Rapid Transit 4s and Interborough Rapid Transit. Following are the closing quotations of February 23:

NEW YORK.

MICHIGAN STATE TELEPHONE.—The permanent organization of the Michigan State Telephone Company has been perfected. Members of the bondholders committee, Isaac Sprague and F. A. Farrar of Boston and Allen B. Forbes of New York, were present, and with the representatives of the various important interests in Michigan which have become identified with the property, elected the following officers and directors: Directors—W. C. McMillan, T. H. Newberry, John T. Shaw, Henry Russel, Frank J. Hecker, A. E. F. White, Elwood T. Hance, all of Detroit; Lewis H. Withey and Dudley E. Waters, Grand Rapids; N. W. Harris, Chicago; A. G. Farr, Chicago; Isaac Sprague, Boston; F. A. Farrar, Boston; Allen B. Forbes, New York; W. A. Jackson, Chicago. Officers—W. C. McMillan, chairman executive committee; W. A. Jackson, president; T. H. Newberry, vice-president; Elwood T. Hance, secretary; John T. Shaw, treasurer; N. W. Harris, chairman of board; L. C. Krauthoff, general counsel; Elliott G. Stevenson, attorney. The active management will be under supervision of Mr. Jackson, president, and the executive committee, of which Mr. McMillan is the chairman, and constituted as follows: W. C. McMillan, Frank J. Hecker, T. H. Newberry, Dudley E. Waters, Elwood T. Hance, A. G. Farr and Allen B. Forbes.

LIGHTING IN NEW YORK.—The West Side Electric Company which at one time loomed up as a possible competitor of the electric lighting interests of the Consolidated Gas Company is likely to pass into the control of the latter. The West Side Company succeeded in obtaining from the board of electrical control under the Low administration the right to lay wires in the ducts of the Consolidated Telegraph and Electrical Subway Company, but never secured a franchise from the Board of Aldermen. Without such a franchise the company's right to operate was open to question, as the Court of Appeals has decided in a case involving the laying of gas pipes that the Board of Aldermen, directly representing the people, is the only body which possesses the right to grant a franchise for such a purpose. Under the permit obtained from the Board of Electrical Control the company has since occupied a section of the subway, but any attempt to extend operations would probably have resulted in expensive litigation. If the Consolidated Gas Company takes over whatever rights and property the other company may have it will again be in undisputed possession of the electric and gas lighting field in this borough.

NATIONAL CARBON ANNUAL REPORT.—The National Carbon Company, of Cleveland, Ohio, reports as follows for the year ended January 31, 1904:

	1904.	1903.	1902.	1901.
Net earnings	$736,441	$594,371	$586,812	$508,739
Preferred dividends	315,000	315,000	315,000	315,000
Balance	$421,441	$279,371	$271,812	$193,739
Charged off, depreciation, etc.	280,429	256,637	217,745	151,456
Surplus	$141,012	$22,734	$54,067	$42,283

The general balance sheet as of January 31, 1904, compares as follows:

Assets.	1904.	1903.	1902.
Real estate, machinery, plants, etc.	$9,025,000	$9,270,000	$9,200,000
Merch. manufacturing and unmanufact'd	618,227	448,216	418,540
Cash	320,713	162,462	235,473
Cash reserved for betterments, etc.	....	....	65,266
Cash reserved for preferred dividend	78,750	78,750	78,750
Bills and accounts receivable	429,189	364,601	354,842
Total	$10,471,879	$10,324,029	$10,352,870
Liabilities.			
Preferred stock	$4,500,000	$4,500,000	$4,500,000
Common stock	5,500,000	5,500,000	5,500,000
Preferred dividend	78,750	78,750	78,750
Accounts payable	93,570	89,278	141,485
Profit and loss (surplus)	299,559	156,001	132,635
Total	$10,471,879	$10,324,029	$10,352,870

The following have been elected directors of the National Carbon Company: John S. Bartlett, N. C. Cotabish, J. S. Crider, D. D. Dickey, H. E. Hackenberg, Hugh H. Hamill, Webb C. Hayes, Myron T. Herrick, James Parmelee and John P. Wilson.

MICHIGAN ELECTRIC COMPANY, of Detroit, Mich., has gone into the hands of a receiver. The officers are Messrs. J. E. Lockwood, president; G. T. Arnold, vice-president, and E. Bullock, secretary and treasurer. Mr. Lockwood in a letter says: "It is, I judge, hardly necessary for me to state that I regret exceedingly having found it necessary to take this step, but in view of the conditions that have existed for some time past and the conflicting tendencies of our trade on one hand, which was continually growing and requiring larger stocks and larger capital to handle, while the manufacturers, on the other hand, have steadily shortened credits, time of settlement and given best prices to cash customers only, there was no alternative. As we have built up the most valuable electrical supply and manufacturers' agency business in this section of the country and can, beyond doubt, do a large and profitable business if we are placed upon a sound financial basis, with proper capital, I sincerely hope a means of reorganization will be found which will permit the full accomplishment of said possibilities." A meeting of the creditors is to be held in Detroit on February 25.

CENTRAL DISTRICT OF PITTSBURG.—At the annual meeting of the stockholders of the Central District & Printing Telegraph Company of Pittsburg, it was decided to increase the capital stock from $10,000,000 to $15,000,000. The new stock will be issued to stockholders at par as needed. The company is now operating 38 main telephone exchanges, 154 branch exchanges and 251 private exchanges, covering 941 towns and cities outside of Pittsburg. This required 24,960 miles of new wire, making the total 143,363 miles. The earnings of the company for the year were $2,733,926.78, an increase of $567,945.52; net earnings, $742,083.97, an increase of $164,003.47. The company now has a total of 56,734 subscribers.

The officers elected were D. Leet Wilson, president; D. F. Henry, vice-president; J. G. Stoakes, secretary; F. L. Stephenson, treasurer; J. H. Boeggman, auditor; M. H. Buehler, general manager.

CHICAGO RECEIVERSHIPS.—Formal announcement has been made of the retirement of James H. Eckels and Rafael R. Govin from the receivership of the North Chicago Street Railroad Company and of the West Chicago Street Railroad Company. Their successors are John C. Fetzer and Henry A. Blair. Mr. Govin and Mr. Eckels will continue as receivers of the Chicago Union Traction Company. Mr. Fetzer has been added to the Union Traction Company receivership. The changes have given rise to a report that a renewal of franchise negotiations with the city is at hand.

NASSAU LIGHT & POWER.—A special meeting of the stockholders of the Nassau Light & Power Company will be held March 4 at 2 p. m. The purpose of the meeting is to act on the following propositions, viz.: To increase the number of directors; to increase the capital stock from $500,000 to $1,500,000, and to alter the certificate of incorporation of the company.

THE CAMP ELECTRIC CONSTRUCTION COMPANY, 41 West Twenty-fourth Street, New York City, has made an assignment to Mr. W. H. Roberts. The company was incorporated on September 27, 1902, with a capital stock of $10,000. Mr. Charles F. Camp is president.

Commercial Intelligence.

THE WEEK IN TRADE.—The unfavorable effects of the continued cold weather are manifesting themselves in a more pronounced manner, but notwithstanding this state of things a hopeful feeling exists as to Spring trade when the weather becomes more propitious. The mid-Winter weather conditions interfere greatly with transportation and outdoor activities generally. There is noted, however, a fair increase of business in jobbing at leading Western and Southwestern centres, and in leading Eastern markets the best jobbing business so far this year is reported. Railway gross earnings in January showed the first decrease reported since February, 1899, and the first decrease reported in January since 1897. Bank clearings during the week, which was broken by holidays, make a poor showing. Important failures were more numerous, small banks and insurance companies, the latter at Baltimore, contributing largely. The total number of failures for the week as reported by *Bradstreet's* was 231, as against 202 the week previous, and 188 the corresponding week last year. Many of the commodities have established new high records, due largely to war influences. The iron trade is still irregular and weak. Some implement men are, however, buying freely of bars and structural material, and wire and rails are in more request at the West. The other metals are slightly firmer, lead alone being higher than a year ago. Copper stiffened somewhat during the week, but there was no particular increase in the demand for domestic consumption, which continues slow. The tendency of the market, however, seems to be toward lower prices. The closing quotations of the New York Metal Exchange were: Lake, 12½ a 12¾ c.; electrolytic and casting stock, 12⅜ a 12⅝ c. The exports so far this month amount to about 5,700 tons, which is a heavy decline as compared with last month's shipments. Trade in lumber and building materials is slack on account of the cold weather.

THE COPPER INDUSTRY.—Discussing the copper industry and export trade, the *Iron Age* makes the following pertinent remarks: "This country is the greatest producer and the most important exporter of the red metal, and has been occupying an increasingly important position as a smelter and refiner of the raw material from adjacent and distant countries. We exported during 1903 copper ingots, bars, etc., to the extent of 310,729,524 pounds, valued at $41,170,059, and imported 136,707,775 pounds, valued at $17,262,148, a very large part of it in the form of converted bars, which were refined in our seaboard electrolytic refineries. We treated besides considerable quantities of foreign matte and ore. We are, therefore, producing or preparing for the consumption of the leading industrial nations of Europe a very large quantity of raw material. We are sending out year after year great quantities of wire bars, cakes and other forms of copper for rolling mill works, and yet we have progressed very little in the desirable work of substituting for exports of the raw material, shipments of higher forms of the metal. Our exports of manufactures of copper were $2,339,729 in 1903, against $2,092,798 in 1902, and $1,842,336 in 1901. Considerable copper, of course, enters into our exports of electrical machinery, which amounted to $5,104,502 in 1903, as compared with $5,937,643 in 1902 and $5,623,442 in 1901. It goes out in considerable quantities as a part of many other lines of machinery, and of alloys and products thereof. But even in these latter little headway has been made. Thus the exports of brass and manufactures thereof showed $2,063,569 in 1903, as compared with $1,800,312 in 1902 and $2,078,178 in 1901. The copper wire and sheet industry has been established in this country for a good many years. Some of the works are splendidly equipped, and are managed by men who have spent their lives in their technical development. At times these works have captured large orders for cable and electrical wires, but the opinion is expressed so far as rolled sheets and similar products are concerned that our makers have pursued a policy commercially, at home and abroad, which has tended to restrict consumption and hamper the most effective utilization of plant."

THE STERLING ELECTRIC COMPANY, Lafayette, Ind., at a recent special meeting, reorganized the board of directors and elected Mr. Walter Doolittle president; Henry A. Taylor, vice-president, and William Coffroth, secretary and treasurer. The reorganization is in line with the policy recently adopted, it having been decided to increase the capital stock from $150,000 to $200,000 and improve and enlarge the plant. The Lafayette (Ind.) *Times* says: "The Sterling Electric Company, an institution in which all of Lafayette takes pride and which has won a high place among the leading manufacturers of electrical appliances, has of late been trimming its sails to the winds of the commercial world. The installing of telephone plants involves the outlay of large sums of money and the business of operating telephone exchanges has been so profitable throughout the country that bonds or other securities on that class of business were very popular with financial institutions. But when money tightened up in money centers a few months ago, and when the promoters of telephone business and toll lines foresaw that there would have to be a short lull in the general activity of the exchange business, the Sterling Electric Company of this city with characteristic sagacity curbed its aggressive spirit and contented itself with a smaller volume of business for the time being—a policy which was pursued by all the wise heads in the same kind of business. The company here surprised all competitors by the increasing volume of trade, and it has more of the same kind of surprise in store just as soon as the conditions warrant the aggressiveness. The board of directors chosen at the stockholders' meeting consists of William Wallace, Charles Murdock, H. A. Taylor, W. E. Doolittle, C. H. Ankeny, W. R. Coffroth, John Wagner, Jr., John Schnaible and A. F. Ramsey, of Crawfordsville. The officers are: W. E. Doolittle, president; H. A. Taylor, vice-president, and W. R. Coffroth, secretary and treasurer. Mr. Coffroth is the new member of the official family and his ability to manage the very important duties connected with the position will be a further assurance of the continued success of the institution."

EQUIPMENT FOR BALDT STEEL PLANT.—The Baldt Steel Company, which is building a large plant at Newcastle, Del., to be devoted to the manufacture of heavy steel castings for steam turbines, locomotives, etc., has awarded contracts through Jeremiah J. Kennedy, consulting engineer, Exchange Court Building, for a 500-hp generating plant, several motors, etc. There will be one 300-hp and another 200-hp Ball & Wood Corliss valve type engine, direct-connected to 200-kw and 150-kw Westinghouse generators. The 200-kw set will be used for power, and the other outfit for lighting purposes. Two large Newton cold saw machines have also been contracted for. They will be direct connected to Westinghouse motors. Some Detrich & Harvey planers and a miscellaneous outfit of lathes and small tools will also be driven electrically. Eventually the power capacity will be increased to 600 kw. The plant is expected to be in active operation by May 1.

WATSON-STILLMAN PLANT.—Some fair-sized contracts for equipment are about to be awarded through G. K. Hooper, consulting engineer, Bowling Green Building for installation in the plant at Aldene, N. J., to be occupied by the Watson-Stillman Company. The plant was formerly known as the Jackson Architectural Iron Works. It will be considerably remodeled. The existing power equipment consists of a 140-hp Ames engine, belted to a General Electric generator. This outfit will be utilized for generating power for the time being. A number of new motors, however, will be installed, and also a new lighting set.

HEINE BOILER ORDERS.—The Heine Safety Boiler Company's New York office has secured a contract from the Syracuse (N. Y.) Lighting Company for a 2,000-hp plant. There will be three boilers. The America Underfeed Stoker Company of Chicago will supply the mechanical stokers. The Wilkesbarre and Wyoming Valley Traction Company, of Wilkesbarre, Pa., is remodeling its plant and will put in a 1,200-hp—in three units—Heine outfit. The American Blower Company, of Detroit, will install induced draft apparatus. The American Woolen Mills, of Lawrence, Mass., has ordered two 300-hp Heine high-pressure boilers.

THE WESTERN ELECTRIC COMPANY, New York City, will install in Philadelphia two direct-current units, one of 100 and the other of 150-hp, to be furnished by the Ball Engine Company, Erie, Pa.

General News.

THE TELEPHONE.

JASPER, ALA.—Mr. E. M. Cranford, of this place, is organizing a company for the purpose of establishing a telephone exchange in Jasper. The capital stock will be $5000, all of which will be absorbed by local business men.

NEW DECATUR, ALA.—The Morgan County Telephone Company is installing telephones in Decatur. This company has been doing business in New Decatur for about a year, but has been unable to get into Decatur until now on account of the opposition of the Southern Bell Telephone Company.

LOS ANGELES, CAL.—The Supervisors of Los Angeles County granted a franchise to the Monrovia Telephone & Telegraph Company for the erection and operation of lines along practically all the highways traversing the ranchos Santa Anita, San Francisquito, Azusa, Duarte, Potrero Grande and Potrero de Felipe Lugo. The franchise is for 30 years. The rental for telephones is not to exceed $36 a year for business houses, or $24 a year for residences. This franchise is for the purpose of extending the Monrovia local telephone service to the neighboring villages and ranches.

BOISE, IDA.—The Rocky Mountain Bell Telephone Company will extend its lines to Thunder Mountain, and from Sweet to Van Wyck, as soon as the weather is more favorable.

ASH GROVE, ILL.—A new company has been organized here to be known as the Ash Grove Telephone Company.

CARBONDALE, ILL.—The Farmers' League and Community Telephone Company has been incorporated with a capital stock of $2500. The directors are: R. M. Montgomery, James England and others.

CAMBRIDGE CITY, IND.—The Central Union Long Distance Telephone Company will install an exchange in this city.

BLOOMFIELD, IND.—The Home Telephone Company may buy the old telephone system of Worthington. If the deal goes through, a number of improvements will be made and the lines extended.

WABASH, IND.—The Central Union Telephone Company has operated in this city since last May without a franchise. The company was ordered by the Council to secure a franchise by October 1, 1903, or remove its property from the streets. The Council drew up a franchise identical in its privileges and restrictions with that of the Home Telephone Company and the company was given until February 1, 1904, to accept it. The company objected to two features of the franchise. One of these is the time limit of ten, instead of twenty-five years. The other was the restriction of the rate to not more than $1.50 per month. The company insists on having the same rate as charged in other cities the size of Wabash. The Council has given the company an ultimatum to accept the franchise during the present month, after which none will be granted, but instead the company's property will be removed from the streets.

MONROE, IA.—The Reasnor Telephone Company has been granted a franchise in this place.

ELLSWORTH, IA.—The Ellsworth Mutual Telephone Association has been incorporated with a capital stock of $10,000. The incorporators are: John H. Sparhoe, Holden Thompson, O. M. Lyders, Barney Peterson, John O. Anderson, Dan Knudson, F. R. Dalby, John P. Holt and M. H. Brinton.

LOUISVILLE, KY.—An ordinance has been introduced in the Council requiring electric companies to place their wires underground and remove the poles from the streets.

DETROIT, MICH.—The Co-operative Telephone Company, of Detroit, has filed a trust mortgage for $40,000 in favor of the Detroit Trust Company, trustee. The money is to be used in the extension of the system.

ATWATER, MINN.—The Atwater Telephone Company has filed articles of incorporation, the capital stock being fixed at $10,000.

ROLLAG, MINN.—The Rollag Telephone Company has been organized with a capital stock of $25,000 to do business in Clay, Wilkin, Becker and Otter Tail counties.

MINNEAPOLIS, MINN.—The Dale station of the Northwestern Telephone Company, at Minneapolis, was visited by fire due to an outside short circuit, and the switchboard was destroyed. The loss on it and on poles and cables was, it is said, $25,000.

WINONA, MINN.—The Winona Telephone Company and the Tri-State Telephone & Telegraph Company have made a contract between themselves by which the latter company agrees to build a long distance telephone line into Winona from the Twin Cities.

ARBELA, MO.—A new company has been organized here to operate a telephone line. D. B. Cravens was elected president.

ST. JOSEPH, MO.—The Bell Telephone Company will expend about $100,000 in the installation of a central energy system in this city. New switchboards will be erected in the main offices with a total capacity of 5000 subscribers.

CHILLICOTHE, MO.—The first convention of the telephone men in this vicinity was held here last week. The officers of the association are: A. Barnes, of Hamilton, president, and H. M. Patterson, of Meadville, secretary and treasurer. The purpose of the meeting was to devise means for the bettering of communication between the towns of this section. Among those in attendance were: C. D. Mayhugh, of Mooresville; A. Barnes, of Hamilton; H. M. Patterson, of Meadville; J. A. Dalbey, W. B. Dorsey, James Burnett, Ed. Steineral and B. F. Brady, of Braymer, and Jessie Flint and C. M. Thompson, of Cowgill.

SUTTON, NEB.—The Sutton Telephone Company has filed articles of incorporation and elected officers as follows: President, P. H. Schwab; vice-president, A. W. Clark; treasurer, James West; secretary, L. B. Stiner.

RENO, NEV.—The line of the Pacific States Telephone Company has been extended as far as this city. The Rocky Mountain Bell Telephone Company is at present extending its lines westward, and the two systems will meet at Lucin. This will give Nevada and Utah points direct communication with San Francisco.

EGG HARBOR CITY, N. J.—The Egg Harbor City Telephone Company has filed articles of incorporation at Trenton, the capital stock being $10,000.

LONG BRANCH, N. J.—The Postal Telegraph & Cable Company has petitioned the Council for permission to lay an underground cable within the borough.

TRENTON, N. J.—The People's Rural Telephone Company, of Wenonah, Gloucester County, has been incorporated with a capital stock of $50,000. The incorporators are: Warren Atkinson, George Horner, Asa Moore and others.

NEWBURG, N. Y.—It is stated that the Hudson River Telephone Company will place its wires underground in this city. The work will cost about $78,000.

MADISON, N. Y.—The Madison Mutual Telephone Company has been incorporated, with a capital stock of $1600, by L. R. Bridge, A. H. Holland, Soleville, N. Y.; W. W. Edgarton, Jr., Bouckville, N. Y.

HAMMONDSPORT, N. Y.—The Hammondsport & Wayne Telephone Company has been organized by farmers of Wayne and Urbana to build a telephone line between Hammondsport and Wayne village, with several branches.

DURHAM, N. C.—The Interstate Telephone Company, which recently gained sole control in Durham, has raised rates to $2 per month for residences and $3.50 per month for stores.

MARION, N. C.—The Marion Telephone Company recently raised its rates and it is reported that many of the patrons have had their telephones taken out. The company had made improvements on the system.

DAYTON, OHIO.—The Home Telephone Company has decreased its capital from $750,000 to $600,000.

MASSILLON, OHIO.—The Massillon Telephone Company has increased its capital stock from $75,000 to $150,000. Improvements and extensions are contemplated.

PERRYBURG, OHIO.—The Maumee Valley Telephone Company has been incorporated with a capital stock of $15,000. The directors are N. L. Hanson and others.

TONTOGANY, OHIO.—The Tontogany Telephone Company has been incorporated with a capital stock of $10,000. The directors are: Jacob Hoffman, B. F. James and others.

CLEVELAND, OHIO.—A deal has been completed here whereby the Federal Telephone Company sold all its interests in the Citizens' Telephone Company, of Columbus, O., to a syndicate headed by Cyrus Huling, of the latter city.

ZANESVILLE, OHIO.—At the annual meeting of the Zanesville Telephone Company the reports of the officers showed the affairs of the company to be in a healthy and flourishing condition. Officers were elected as follows: F. S. Dickson, president; S. M. Granger, vice-president; J. B. Rhodes, secretary and general manager; R. W. Judd, treasurer.

RAVENNA, OHIO.—The affairs of the Portage County Telephone Company are in an excellent condition, as shown by the report presented at the annual meeting of the company. The company now has 1566 subscribers in Portage County, of which 572 are in Ravenna, 587 in Kent, 221 in Mantua and 186 in Garrettsville. The company has spent $9000 in construction work since March last.

CLEVELAND, OHIO.—The annual meeting of the stockholders of the Cuyahoga Telephone Company was held in this city recently, and all of last year's directors were re-elected. No effort was made to create new business during the year, and an increase of a little more than $10,000 in gross earnings was due rather to the substitution of paying subscribers in the place of those rated as slow collection. President Dickson's annual report shows that the company now has 10,466 telephones in use. He expresses satisfaction at the results of the profit-sharing plan and stated that it would be continued. The company now has a surplus of $15,401.

GUTHRIE, O. T.—A merger of the Pioneer Telephone Company, with headquarters at Guthrie, the Long Distance Telephone Company, of Shawnee, and the North American Telephone & Telegraph Company, of Muskogee, I. T., has been effected. A new charter will be taken out.

ALTOONA, PA.—The Bedford-Fulton Telephone Company and the Extension Telephone Company are to be merged.

COLUMBIA, S. C.—A bill has been introduced in the South Carolina Legislature placing telephone companies under the control of the Railroad Commission.

RICHMOND, VA.—The North Fort Telephone Company, of McDonald's Mill, Montgomery County, has been incorporated with a capital stock of $500 to $5000. Mr. A. P. Bennett is president.

STANDARDSVILLE, VA.—The Swift Run Telephone Company, of Standardsville, has been incorporated. E. D. Ott is president. The capital stock is $1200 to $5000.

PALOUSE, WASH.—The Palouse Deep Creek Telephone Company has been incorporated to construct a telephone line from Palouse to Freese. George H. Sawyer is president. A barb-wire fence will be used for the line until spring, when an overhead line will be constructed.

FOOTVILLE, WIS.—The Footville Telephone Company has increased its capital from $4000 to $10,000.

TURTLE LAKE, WIS.—The City Telephone Company has been incorporated with a capital stock of $2000. The directors are: F. E. Fisk, John Hogan and others.

SPARTA, WIS.—The Western Wisconsin District Independent Telephone Association has been formed here. It embraces all of the independent systems in the western part of the State.

ELECTRIC LIGHT AND POWER.

MONTGOMERY, ALA.—The Coosa Water Power Development Company, with $250,000 capital, has been formed to develop a water power in Calhoun County, Ala. The Industrial Finance & Trust Company, of Birmingham, is fiscal agent for the new concern. It is said that northern capital is interested in the movement.

LITTLE ROCK, ARK.—The new power house of the Little Rock Railway & Electric Company, in this city, is now in operation. The new power house when completed will cost about $350,000, with its equipment. The old power house will be used for electric light supply.

CORONA, CAL.—The stockholders of the Corona Gas & Electric Company have voted to issue $40,000 bonds for improvments to the plant.

SANTA ROSA, CAL.—A committee has been appointed to select an engineer and draw up plans, etc., for a municipal lighting system. An election will soon be held to vote on issuing bonds for same.

DOWNEY, CAL.—The Downey Electric Light & Power Company has been granted a franchise to use certain streets and highways in and around the village of Downey for the erection of a system of lines and conduits for the transmission of electric light and power. The life of the franchise is to be 30 years, and work on the plant must be commenced within six months and finished in three years. After March 15, 1909, the company is to pay to the county 3 per cent. of the gross receipts.

STOCKTON, CAL.—The City Council has granted R. G. Paddock a franchise for installing a heat and power system in the city, and it is generally believed that he represents H. E. Huntington, who will build an electric railroad from Stockton to Bakersfield at an early day. Only one bid was presented, and upon being opened it was found that Paddock had offered $130. Immediately an ordinance awarding him the privilege was passed. For several days past it had been rumored that other bidders would be present, but it seems that they were not forthcoming. For over a month, there has been quite a lively fight between the Stockton Gas & Electric Company and the American River Electric Company, and prices of electricity were cut to the lowest figure ever made in the State. Then a truce was declared, and while both companies assert that they have not reached any understanding, or combined, it is current report that they are not doing the same cutting of rates that they were.

WASHINGTON, D. C.—Bids will be received March 1 at the Bureau of Supplies and Accounts, Navy Department, for furnishing the navy yards, at Norfolk, Va.; Charleston, S. C., and Port Royal, S. C., a quantity of electric blowers, electric fans, electric traveling crane, railroad track, galvanized sheet steel, pipe fittings, marine cement, etc. H. T. B. Harris, Paymaster-General, U. S. N. Bids are wanted April 12 for electrical supplies. Wm. M. Meredith, Director Bureau of Engraving and Printing, Treasury Department.

VIDALIA, GA.—John W. Wiggins, of Savannah, has secured an electric light franchise in Vidalia, and is now purchasing the necessary machinery in the north.

KEITHSBURG, ILL.—It is reported that the electric light plant owned by T. A. Marshall will be rebuilt.

VIRDEN, ILL.—The Virden Electric Light Company has been incorporated, with a capital of $15,000. J. N. Hairgrove, U. G. Tucker and C. W. Carr are the incorporators.

MOORESVILLE, IND.—The Public Service Company, of Mooresville, has been incorporated, with a capital of $50,000, to build water works and an electric light plant. Directors: Wm. B. Vestal and Jas. S. Hubbard, both of Mooresville.

WHITING, IND.—The Lake County Light & Power Company, of Whiting, has filed articles of incorporation. The capital stock is $100,000. The incorporators are: R. J. Carey and Arthur Young, of Chicago, and Samuel T. Chase, of Lake Forest, Ill.

TERRE HAUTE, IND.—The Terre Haute Electric Light Company is to install a 1000-hp turbo-generator in its new power station on the river front in this city. The apparatus is to be supplied by the General Electric Company, the contractors being Stone & Webster.

RICHMOND, IND.—The Richmond Light, Heat & Power Company has filed a mortgage in favor of the Continental Trust Company, of New York, on its property for $300,000, covering an issue of bonds in that sum which will be sold to meet cost of improvement for the local plant. The company is owned and officered by New York capitalists, and is making a damaging fight against the Richmond municipal plant.

NEW CASTLE, KY.—The Town Trustees have granted a franchise to the New Castle Electric Light, Heat & Power Company.

LOUISVILLE, KY.—An ordinance is to be introduced in the General Council requiring all wires in the downtown district to be placed underground.

NEWPORT, KY.—J. B. Morlidge, City Engineer, writes that the city contemplates constructing a municipal electric light plant. Ten thousand dollars has been set aside by the General Council toward it, and a similar sum will be set aside each year until the entire cost of construction is covered.

BRUNSWICK, ME.—The directors of the Brunswick Electric Light & Power Company, at a special meeting, have voted to install an auxiliary steam plant in the old gas house, which the company purchased some time ago. In the past two or three years there have been several occasions when the present plant has been bothered about securing power. According to the terms of agreement, the Cabot cotton mill has the first call for the water from the upper fall. As the electric light plant derives is power from the same source, when the river is low and the Cabot mill is running, the electric light plant is obliged to shut down. Thus far this year nearly every day the power has been shut off early in the morning, and until 6 o'clock in the evening it has been impossible to get either electric light or power. The installation of a steam plant will insure light and power at all times of the day. Mr. A. Hopkins is superintendent.

SAULT STE. MARIE, MICH.—The Edison-Sault Electric Company has decided to improve the electric light plant.

MARQUETTE, MICH.—Edw. P. Burch, of Minneapolis, Minn., has been selected by the Light & Power Commission to advise with the Commission with regard to the enlargement of the electric light plant.

JACKSON, MINN.—The Council has voted to issue $5000 bonds to improve the electric light plant.

SWEETWATER, MINN.—The citizens have voted bonds for water works and an electric light plant.

STILLWATER, MINN.—R. S. Feurtado, of Chicago, superintendent of the Western Gas & Investment Company, writes in regard to improvements contemplated by the Stillwater Gas & Electric Light Company and the Apple River Power Company, that it is proposed to construct a 20-ft. dam and a 1000-hp electric power plant.

BEELZONA, MISS.—Bids will be received April 5 by the Mayor and Board of Aldermen for constructing an electric light plant and water works.

BURLINGTON JUNCTION, MO.—It is reported that Robt. Crooks will establish an electric light plant here.

HOPKINS, MO.—Chas. Hartness is preparing to put in an electric light plant.

JOPLIN, MO.—The City Council has granted an electric light and power franchise to W. G. Sergeant.

GREAT FALLS, MONT.—Max Hebgen, of Butte, is preparing plans for improvements to the plant of the Great Falls Electric Light & Power Company. The probable cost of improvements is $75,000.

RENO, NEV.—The directors of the Nevada Power, Light & Water Company have decided to enlarge the power plant.

ASBURY PARK, N. J.—The Beach Commissioners have awarded to the A. D. Granger Company, of New York, N. Y., the contract for constructing the electric light plant on the beach for $10,773.

SANTA FE, N. M.—The Capital Light & Power Company is said to have sold its interests to J. C. Bonner & Company, of Toledo, O., and associates. The company announces its intention to establish a power plant on the upper Pecos. Power and light will be furnished to Santa Fe, Albuquerque and Las Vegas. The company will issue bonds to the amount of $300,000, and will begin work in the spring.

VALATIE, N. Y.—It is proposed to construct an electric light plant at a cost of $12,000. R. E. Lasher is Village President.

PENN YAN, N. Y.—At the next annual charter election the citizens will vote on the proposition to install a municipal electric light plant.

WARSAW, N. Y.—The Warsaw Gas & Electric Company has decided to install a new direct-current dynamo, and a new outfit of enclosed arc lamps for street lighting.

ALBANY, N. Y.—The application of the Niagara, Lockport & Lake Ontario Power Company's franchise bill to any city is removed by amendments to the bill adopted by the Assembly Codes Committee in executive session. The amendment strikes out the provision giving the corporation power of eminent domain in any city, and requires consent of the local authorities for the use of any streets or the erection of poles.

MOORESVILLE, N. C.—B. A. Troutman, of Mooresville, is interested in the construction of an electric light plant.

CONCORD, N. C.—The town of Concord is figuring on a new electric light plant to cost about $18,000. The old plant may possibly be bought by the town, however.

CHARLOTTE, N. C.—The Light Committee has decided to recommend that the city make a contract with the new Catawba Electric Power Company, of Fort Mill, S. C., to supply lights at $54 per annum for the first 150 lights and $48 for all over that number. The price paid the Charlotte Consolidated Construction Company at present is $90 per light per year. The new company expects to have power available in four months.

COLUMBUS, OHIO.—An electric light plant is to be provided for the State penitentiary.

ASHLAND, OHIO.—The City Council is discussing the proposition to install a municipal electric light plant.

TROY, OHIO.—The business men of Troy have under consideration the construction of an electric light plant.

LORAIN, OHIO.—The Citizens' Gas & Electric Company, of this city, has decided to construct a new plant, plans for which are now being prepared. The company now uses the plant of the Lorain Street Railway.

CLEVELAND, OHIO.—The Board of Public Service has decided to recommend favorably the entering into of a contract with the Cleveland Electric Illuminating Company for street lighting, at $75 per lamp per year.

ONTARIO, ORE.—E. H. Test and A. N. Soliss have secured a franchise for an electric light and power plant.

UNIONTOWN, PA.—The Masontown Electric Company, of Uniontown, has been incorporated with a capital of $5000.

WYALUSING, PA.—The Wyalusing Light, Heat & Power Company, of Wyalusing, has been incorporated with a capital of $10,000.

YANKTON, S. D.—The city may buy the electric light plant or build a new one.

WEBSTER, S. D.—Between $2000 and $2500 will be expended for improvements to the electric light plant.

FARMERSVILLE, TEX.—The Farmersville Mill & Light Company has been organized here with a capital stock of $50,000.

BATSON, TEX.—The Sour Lake Light & Power Company, of Sour Lake, is preparing to extend its transmission line to this place for the purpose of furnishing light and power here. The current will be brought here from the Saratoga station of the company, situated about five miles distant.

BIG SANDY, TEX.—The large dam of the A. K. Seage Box Company across the Big Sandy near here is to be immediately repaired and the water power thus obtained is to be used for generating electricity for lights and power for this town. The A. K. Seage Box Company can give information. This company also contemplates establishing a water works plant here.

ELLENSBURG, WASH.—The citizens have voted to issue $20,000 bonds for an electric light plant.

PROSSER, WASH.—The Prosser Falls Land & Irrigation Company has petitioned for a franchise for an electric light plant.

SPOKANE, WASH.—Samuel Storrow, chief engineer Northwestern Gas & Electric Company, Los Angeles, Cal., writes that it is proposed to develop the power of the Walla Walla River. The probable cost of the work will be $250,000.

LAFARGE, WIS.—The Lafarge Electric Company has been incorporated, with a capital of $6000.

BURLINGTON, WIS.—It is proposed to construct a municipal electric light plant for both street and commercial purposes here.

The Electric Railway.

GREELEY, COL.—The Greeley & Northern Railroad & Utility Company has filed articles of incorporation, with George H. Sethman as general manager. The company is organized for the purpose of building an electric road through northern Colorado from this city to a connection with the Burlington Railroad. The power plant of the company will also be utilized in furnishing this city with electric light. The electric system will be over 25 miles in length.

AUGUSTA, GA.—At the annual meeting of the North Augusta Companies, of Augusta, Jas. U. Jackson was re-elected president of the Augusta Railway & Electric Company; the Augusta & Aiken Railway; the North Augusta Electric & Improvement Company and other development companies. Chas. G. Goodrich was elected vice-president of the Augusta Railway & Electric Company.

BOISE, IDA.—I. W. Anderson and associates, of Philadelphia, have acquired by purchase the system of the Boise Transit Company, and articles of incorporation of the new company have been filed. Mr. Anderson is president of the company, and Charles A. Hutchinson, of this city, will act as general manager. Improvements and extensions of the system will be commenced at once.

NEW YORK, N. Y.—President E. A. Maher, of the Union Railway Company, has applied to the Board of Aldermen for franchises to effect 13 new connections, including the right to cross several bridges into Manhattan, thus effecting a more perfect physical relationship with the Metropolitan system.

DALLAS, TEX.—Parties who propose to construct and operate an interurban electric railway between Dallas and the town of Waxahachie, Tex., have submitted a proposition to the Commercial Club, of this city, which, if favorably considered, will insure the consummation of the project. The distance is about 30 miles. The secretary of the Commercial Club, Dallas, can give information.

Obituary.

MR. E. A. GAY.—Mr. Eugene A. Gay, receiving clerk of the Western Union Telegraph Company in Albany, died suddenly of pneumonia there on February 23. He was one of the best-known telegraph operators in this State, and was in charge of the Western Union branch office in the old Delavan House during the famous political campaigns between 1860 and the time of the Delavan's destruction. He was a brother of Ward Gay, the artist.

MR. J. M. FORBES.—Mr. J. Malcolm Forbes, widely known as a patron of light harness racing and as a yachtsman, died on February 19 at Milton, Mass. Mr. Forbes had been suffering from an internal malady for about a week. Two operations, performed as a last resort, failed. Mr. Forbes was nearly sixty years of age. He was for many years a heavy shareholder and a director in the American Bell Telephone Company and other properties. He was formerly Commodore of the Eastern Yacht Club, and in former years actively participated in the defense of the America's Cup. American Telephone & Telegraph was weak on the Boston Stock Exchange on news of Mr. Forbes' death.

MR. J. A. ROCHE.—Mr. John A. Roche, one of the leading officers of the Otis Elevator Company, died suddenly in Chicago, on February 10. He was born in Utica, N. Y., August 12, 1844, and after graduating from the high school, removed to New York, where he learned the trade of a pattern maker. He went to Chicago in 1869 and became a dealer in machinery, and for many years was the Northwestern representative of the firm of J. A. Fay & Company, of Cincinnati. He entered politics in Chicago, and was elected mayor on the Republican ticket, holding office from 1887 to 1889. After retiring from office he became vice-president of the Crane Elevator Company and later the managing director of the Otis Elevator Company. From 1893 to 1897 he was the president of the Lake Street Elevated Railroad Company and was widely known amongst electrical men in the west.

MR. FRANCIS FORBES.—We regret to note that Mr. Francis Forbes, member of the law firm of Forbes & Haviland, died suddenly from pneumonia at his home in New York City, on February 18. He was born in Rochester, N. Y., and graduated from Rochester University in 1865. After spending some time in study in France, he entered Columbia Law School, from which he was graduated in 1870. He represented this country at the International Convention of Industrial Marks in Madrid in 1890, and later at Brussels in 1897. He was a member of the State Constitutional Convention in 1894, and was recently appointed a delegate to the International Convention of Jurists at the World's Fair at St. Louis. He belonged to the University and Lawyers' Clubs. Mr. Forbes leaves a widow, daughter of the late Robert Bonner, two sons, and two daughters. Mr. Forbes had from time to time a good deal to do with electrical and mechanical patent litigation, and was an active and liberal member of the New York Electrical Society for a great many years.

MR. JACOB HESS. —Mr. Jacob Hess, for many years a leader in New York Republican politics and a member of the last bi-partisan Police Board, died on February 19 at his home in Manursing Way, Rye, N. Y., where he had lived for months in comparative retirement. Mr. Hess was born in Hesse-Darmstadt in 1847, but was brought to this country when only two years old. After a brief course in the common schools he became a butcher's boy in Washington Market, New York City. He embarked in business for himself as a commission dealer in meats in West Washington Market when he was nineteen years old, and was said to have accumulated $100,000 when he made his first start in politics, in 1874, being elected Assemblyman. The next year he was elected Alderman at Large. He declined the nomination for Sheriff in 1876. Mayor Wickham in 1877 appointed Mr. Hess a Commissioner of Schools. Mayor Cooper appointed him Commissioner of Charities and Correction in 1879, and he was elected president of the board. He served until May, 1885, when he retired, being made a member of the new Board of Electrical Control two months later. He became president of that also, during a very important period, and held office until Tammany came into power in 1898. Mr. Hess' only son, Seymour Griswold Hess, a young man of great promise, died at his father's house in 1897, a short time after his graduation from Columbia University.

Personal.

MR. W. MARCONI is expected, it is said, to leave Europe for America on March 23 on the Italian man-of-war "Carlo Alberto."

MR. FRED SARGENT, the consulting and designing electrical engineer, has sailed on a trip to Europe, to be gone some weeks, during which time he will study power plant development there in its latest illustrations.

MR. LOUIS J. MAGEE, who represents the Allegemene Elektricitats Gesellschaft in this country as resident director, has been quite ill with bronchitis and detained at home by illness. We are glad to record his recovery.

MR. JOSEPH JEFFERSON, the veteran distinguished actor, has just celebrated his 75th birthday by becoming president of an electric light and power company at West Palm Beach, Fla., where he has large property interests.

MR. H. SHINOMWIA, of the department of communication of Tokio, Japan, arrived in New York last week by steamer from England, en route for home. He has been abroad for over a year studying the postal and telegraph services of Europe.

MR. R. O. HEINRICH, of the European Weston Electrical Instrument Company, of Berlin, is expected shortly in this country, where a great many old friends will be glad to renew their acquaintance and intimacy. It is now some years since he returned to Europe.

MR. FREDERICK A. WALDRON, hitherto superintendent of power and plant for the Yale & Towne Manufacturing Company, has opened offices as consulting engineer at Stamford, Conn., to advise on matters relating to the construction, arrangement and equipment of power plants.

MR. CHARLES L. BROWN has associated with him his brother, Mr. Stuart H. Brown, and has incorporated his electrical contracting business at Chicago under the name of the Brown Electrical Construction Company. The new concern has taken offices in suite 505-6-7, Ellsworth Building, Dearborn St.

MR. C. H. NORTH, president and general manager of the North Electric Company, of Cleveland, O., was a recent visitor to New York. Mr. North has done a great deal for the cause of rural telephony, as well as in the invention and perfection of apparatus. His connection with telephony dates back to the beginning.

MR. GEORGE W. FOWLER, who for several years past has been connected with the engineering department of the C. & C. Electric Company, has resigned his position with that company and will hereafter be associated with Mr. George D. Beinert, the electrical contractor, with offices in the Bible House, New York City.

MR. N. S. HOPKINS has severed his connection with the Fort Wayne Electric Works, where he had charge of the direct-current motors and generators, as engineer. He had previously spent three years at Schenectady and five years at the Lynn factories of the General Electric Company, as designing engineer on numerous lines.

MR. W. B. POTTER, head of the railway department of the General Electric Company, has sailed for the West Indies, in search of health and warmer weather. He has been struggling for some weeks past with incipient grip and pneumonia, but would not let go until the doctors and his associates insisted he must break away, or pay the penalty.

WHITEHEAD, SUMNER, HARKER & COMPANY announce the formation of this concern, with headquarters, as machinery merchants and exporters, at 196 Deansgate, Manchester, England. The firm comprises Messrs. James P. Whitehead, Bertram Sumner, John Harker and Julien Prêcheur. Arrangements are being made for branch houses and agencies.

MR. JAMES T. MAXWELL, general agent of the Philadelphia Electric Company, has, we regret to state, had the deep misfortune to lose his wife. Mrs. Maxwell was well known to many in the electrical field, having attended the conventions of the Association of Edison Illuminating Companies with her husband, and having made many friends and acquaintances at such times.

MR. G. M. ABBOTT.—The stockholders of the Cincinnati, Newport & Covington Street Railway Company have elected George M. Abbott to succeed Henry Burkhold on the board. This company is a subsidiary concern of the Cincinnati, Newport & Covington Light & Traction Company. It is said that Mr. Abbott will also succeed Mr. Burkhold as a director of the latter company.

MR. W. L. HODGES has been appointed sales manager of the National Battery Company, with offices at 253 Broadway, New York, and has resigned his position with the Audit and Appraisement Company of America. Mr. Hodges, it will be remembered, was for some time associated with Dr. Louis Duncan and was particularly active in telephone work in Philadelphia.

MR. G. H. KIMBALL, of Buffalo, N. Y., has requested us to state in his behalf that in regard to our recent article on proposed electric power transmission work at Omaha, he did not serve as an arbitrator in connection with the matter as intimated, and that he was in no way connected with it after the late days of August, the arbitration being held three or four months later.

MR. CHARLES LANG has resigned his position with the Wheeler Condenser & Engineering Company, after ten years' service with that company. During that period Mr. Lang advanced from office boy to purchasing agent, and later entered the company's engineering department. He is at present considering a number of excellent offers from several sources, and in the meantime is taking a much needed rest.

MR. W. J. BAUGHMAN, who for two years was superintendent of the Stanley Electric Manufacturing Company's factory at Pittsfield, Mass., and who more lately had been made head of the production department, has succeeded Mr. J. H. Kelman as superintendent, on the latter's resignation. Mr. Frank R. Whittlesey, head of the purchasing department, has succeeded Mr. Baughman as head of the production department.

PROFESSOR HIMSTEDT, of the University of Freiburg, Germany, has continued investigations as to the existence of radium in nature, and has extended those formerly made of rain water and of the soil with reference to the presence of radium. He has arrived at the conclusion that radium occurs more frequently in our surroundings than has heretofore been suspected. According to his experiments, all natural springs of water and also the petroleum wells possess a heavy gas, whose radiations are similar to, and probably identical with, radium.

MR. C. G. Y. KING, a well-known member of the engineering staff of the Chicago Edison Company, has been visiting the east to deliver a series of lectures on the new steam turbine plant of that corporation, accompanied by a fine series of lantern slides. The first lecture was delivered in New York City before a large gathering of General Electric representatives. Mr. King then went on by invitation to Boston and there delivered the lecture twice on a single day, once before a similar gathering and once before the Massachusetts Institute of Technology.

MR. W. R. GARDENER, assistant treasurer and manager of the Pittsfield, Mass., Electric Company, has been writing in a clear and popular way lately to the local papers, explaining the nature of electrolysis and its cure. There has been a good deal of interest in the subject locally, owing to the fact that some underground cables of the New England Telephone & Telegraph Company had needed overhauling, apparently on account of the electrolytic action of stray current from the Pittsfield trolley system.

MR. ANDREW CARNEGIE.—Mr. Carnegie has added another lot to the site on Thirty-ninth St. which he acquired last year for the united engineering societies. The house at 33 West Thirty-ninth St. was conveyed by John Thacher to Robert A. Franks, who is Mr. Carnegie's representative and has taken title for him to the adjoining houses, 23 to 31 West Thirty-ninth St. The abutting property at 32 and 34 West Fortieth St. is held by the Engineers' Club. The stated consideration in the transfer recorded was $1,000. For some of the other Thirty-ninth St. houses Mr. Carnegie paid $110,000 each.

MR. ADELBERT P. HINE, superintendent of the Coe Brass Company plant of the American Brass Company, has been made general superintendent of all the plants. Mr. George Braham, who has been assistant superintendent of the Coe Brass Company, has been made superintendent, and Mr. William E. Besse assistant superintendent. The purchasing for all the American Brass Company's plants is now done by the American Brass Company at their Waterbury office. Mr. F. L. Adams, formerly general manager of the Holmes, Booth & Haydens Company, has been made assistant purchasing agent of the American Brass Company.

MR. CHARLES WIRT, vice-president of the Wirt Electric Company, of Philadelphia, sailed last week on the steamer "St. Paul" for England, to be a month in that country. His health has been very poor lately, and he hopes to build it up during this vacation. While in London he will stay at the Grand Hotel, and make a study of the electrical situation. The Wirt Electric Company has recently arranged to have a new building erected for them in Philadelphia, at the corner of Pennsylvania Railroad and Germantown avenue. The new shop has been specially designed for their work, and will be up to date in all particulars.

MR. D. M. LORD.—The Chicago papers recently devoted much space to the growth of the advertising business as a whole, and that of Lord & Thomas in particular, owing to the retirement of Mr. D. M. Lord, the senior member of the firm, who leaves active business life with a competence. The business has been one of the most aggressive and progressive of its kind in the country, having in recent years been under the active management of Mr. A. L. Thomas, who has succeeded Mr. Lord to the presidency and will continue at the head of the firm. Mr. C. R. Erwin, the new vice-president, has been connected with the company for 20 years, and is therefore a veteran in the field; associated with him and Mr. Thomas is Mr. A. D. Lasker, the secretary and treasurer. To give some idea of the growth of advertising as a whole, it might be stated that in two years the business of Lord & Thomas alone has increased one million dollars in the billing, and in the one month of January in 1904 this house has booked $750,000 in advertising contracts.

Trade Notes.

THE WESTERN TELEPHONE MFG. CO. has leased quarters in the Atlantic Building, 42 West Jackson Boulevard, Chicago, Ill., and will move its factory and office to that address March 5.

THE A. ROSENBERG COMPANY, of Baltimore, makers of water motors, water fans, etc., advises us that it was not affected by the recent great fire there, being beyond the zone of conflagration.

THE ELECTRIC APPLIANCE COMPANY, Chicago, announces that it has added to its already immense stock of electrical supplies a complete line of trolley cars and wheels, and is prepared to quote on railway overhead material.

THE WILLIAM TOD COMPANY has recently opened a New York office at 29 Broadway, and placed it in charge of Mr. George F. Woolston. The company is builder of Corliss and medium-speed engines for all electrical work in lighting and railway plants, etc.

THE NEW NOVELTY COMPANY.—J. M. Stafford, F. J. Meyers and others have organized and incorporated the New Novelty Company, with offices in Vincennes, Ind. The company will manufacture electrical burglar and fire alarms, fire escapes, double-cylinder gas engines and electrical apparatus.

FAIRBANKS, MORSE & CO., Franklin and Monroe streets, Chicago, have issued a new edition of their catalogue on hoists and mining machinery operated by gas, gasoline, crude oil or producer gas. They also make a complete line of machinery operated on steam, including both flat friction and geared hoists. Copies can be obtained on application.

BULLOCK IN BALTIMORE.—The recent fire in Baltimore destroyed the offices of the district manager of the Bullock Electric Manufacturing Company. Temporary quarters have been located at 303 Cortlandt St., that city, where all inquiries should be addressed. The office is working with its full force, and is ready to take care of all business offering.

"ARKLESS" FUSES, formerly made by the McBride Manufacturing Company, are now controlled by the Horton-Massnick Company, of 11-23 Detroit, Mich. These fuses with flexible terminals are used regularly by the Detroit Edison Illuminating Company in furnishing its patrons with free fuse renewals; and nearly all the old dangerous open-link fuses in Detroit have been replaced by "Arkless" cartridge fuses.

THE WARD LEONARD ELECTRIC COMPANY, Bronxville, N. Y., has issued a new catalogue, No. 19,038, covering resistance units of its manufacture. Three new types of resistance units are catalogued, with tables of capacities and resistances. A cut is shown showing various methods of mounting these resistance units for telephone, telegraph work, etc. Those interested can receive copies of the catalogue by applying for it.

THE S. R. SMYTHE COMPANY, of Pittsburg, Pa., represented in New York City by Dr. Oskar Nagel, 90 Wall St., has just issued a catalogue on suction gas producers for gas engines, showing the simplicity and advantages of the construction and the economy in fuel attained by such apparatus and practice. These producers are built in units from 5 to 150 hp, and yield 1 hp hour per pound of coal, no boiler or gas holder being required.

SMITH STORAGE BATTERY COMPANY, of Binghamton, N. Y., has just issued in neat form Catalogue No. 2, devoted to its Smith storage battery for lighting, power, automobiles, etc. This battery is in some styles of the tray type, *i.e.*, has its plates horizontal, with plates formed from rolled lead of concentric circular gridding. The battery is fully illustrated and described, in both the horizontal and vertical types. The catalogue is most interesting.

THE CENTRAL ELECTRIC COMPANY, Chicago, reports an extremely gratifying business on American Circular Loom non-metallic flexible conduit, on which it has been and is still quoting some extremely low prices. The company states that the trade generally throughout the country has been quick to take advantage of these prices, and that it has received some very large orders. The company urges that those of its trade who have not already done so, should make it a point to write for quotations on this class of goods.

MR. E. B. LATHAM.—Among the evidences of the growth of foreign business, one of the amusing incidents is the shipping of fans in midwinter. The early part of February E. B. Latham, of New York, sent to Shanghai, China, 200 of the well-known Tuerk alternating-current ceiling fans manufactured by the Hunter Fan & Motor Company, of Fulton, N. Y. That export business creates an almost all-the-year-'round manufacture is illustrated by this shipment at the particular season of the year, and during such phenomenally cold weather.

CROCKER-WHEELER FLYERS.—The Crocker-Wheeler Company, Ampere, N. J., has issued a set of 17 flyers on the subject of machine tool equipments, which will be of interest not only to electrical men but also to machine tool users. One of the flyers discusses at length the subject of electric drive for machine tools with methods of variable speed control, the others being devoted to examples of applications of Crocker-Wheeler machines for such purposes. The flyers are fully illustrated with views of the various classes of machines considered.

TRAIN LIGHTING.—Col. J. T. Dickinson, vice-president of the Consolidated Railway Electric Lighting & Equipment Company, general offices Hanover Bank Building, New York, is authority for the statement that the Consolidated Company has more of its "Axle Light" equipments of electric car lighting in use on the best cars constituting the finest trains of leading railway lines than all other systems of electric car lighting combined. He also claims that the chief mechanical officials of several of the great railway systems in the country, where a large number of "Axle Light" equipments have been in service for the past few years, have concluded that the system is the cheapest to install and maintain and the most efficient system of electric car lighting ever yet devised. Each car carries its own independent electric car lighting apparatus, ready for immediate and constant use, no matter in what service the car may be placed.

Record of Electrical Patents.

UNITED STATES PATENTS ISSUED FEBRUARY 16, 1904.

[Conducted by Wm. A. Rosenbaum, Patent Attorney, 140 Nassau St., New York.]

750,829. VERTICALLY-SWINGING SUPPORT OR SHELF; Jacob S. Detrick, Baltimore, Md. App. filed Sept. 9, 1903. (See page 403.)

750,845. SWITCHING APPARATUS; John S. Goldberg, Chicago, Ill. App. filed Nov. 26, 1902. (See page 403.)

751,081. COIN-CONTROLLED TELEPHONE APPARATUS; Sherwood J. Larned, Chicago, Ill. App. filed Dec. 3, 1903. (See page 403.)

751,228. CABLE-HANGER; Richard H. Villard, New York, N. Y., and Herschel P. Copeland, Jersey City, N. J. App. filed Aug. 5, 1902.

752,037. ELECTRIC TRAIN SERVICE; Melvin D. Compton, New York, N. Y. App. filed Dec. 2, 1901. The speed of a generator driven from the locomotive axle is varied by throwing disks of different diameters into and out of engagement by means of pneumatic pistons which are controlled automatically by the condition of the current in the various circuits of the system.

752,048. ELECTRIC METER; Thomas Duncan, Lafayette, Ind. App. filed Oct. 23, 1903. A friction-compensating coil for producing a field for the armature, and switching mechanism for including more or less of said coil in circuit.

752,059. SYSTEM FOR OPERATING STOCK BOARDS; Geo. S. Gallagher, New York, N. Y. App. filed April 29, 1903. Stock quotations are printed upon tapes that are moved across the face of a quotation board.

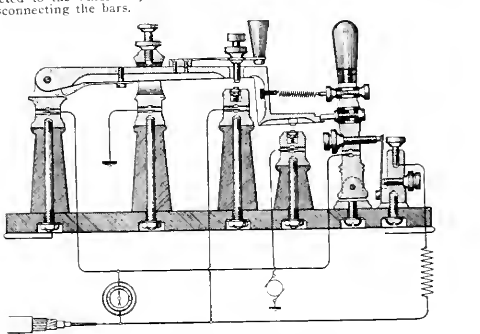
752,081. CAR SIGNAL; Geo. M. Lane, Brooklyn, N. Y. App. filed May 14, 1903. Details.

752,084. RAILROAD SIGNAL; John K. Leedy, Roanoke, Va. App. filed Nov. 10, 1902. Details.

752,097. AUTOMATIC STARTER FOR ELECTRIC MOTORS; William C. O'Brien, Baltimore, Md. App. filed May 4, 1903. Details.

752,121. TROLLEY FINDER; Elisha S. Stitt, Newton, Mass. App. filed Oct. 17, 1902. A guiding fork for the wheel arranged to be held in operative position by tension on the cord.

752,125. PANEL BOARD; Hans O. Swoboda, East Orange, N. J. App. filed Dec. 22, 1902. Switches comprising two blades are arranged between the bus bars, one blade being connected to one bar while the other is connected to the other bar, the movement of the switch thus connecting and disconnecting the bars.



752,158. Key for Cable Testing.

752,127. RAILWAY SWITCHING AND SIGNALING APPARATUS; John D. Taylor, Buffalo, N. Y. App. filed Jan. 12, 1901. Details of a locking mechanism for the signals.

752,139. TROLLEY CATCHER; William C. Young and Johnson McMahon, Buffalo, N. Y. App. filed June 1, 1903. A spring normally under tension is released when the trolley wheel leaves the wire to contract and draw the pole downward.

752,150. ELECTRIC SELECTIVE SYSTEM; Julien A. Gehrung, St. Louis, Mo. App. filed Feb. 8, 1902. A series of sending keys adapted to send varied impulses of different polarities, a series of selected magnets having correspondingly graded electromotive forces and two groups of interdepending circuit closers arranged parallel with opposing pairs operatively connected to single selective electro-magnets.

752,158. KEY FOR CABLE TESTING; William B. Hale, Chicago, Ill. App. filed April 29, 1901. A key having a number of contacts connected with the generator, the line and the testing instrument, are operated in succession and in combination with a detent lever to obtain the test.

752,168. DYNAMO ELECTRIC MACHINE; Hans Holzwarth, Hamilton, O. App. filed Nov. 21, 1903. Radial spaces between the armature plates communicate with the interior of a hollow shaft through which air is directed for ventilating purposes.

752,184. HANGER FOR TELEPHONE-TRANSMITTERS; Michael Setter, Chicago, Ill. App. filed May 8, 1902. (See page 403.)

752,192. ELECTRIC SWITCH; Charles C. Badeau, Swissvale, Pa. App. filed Aug. 12, 1903. Certain improvements in that class of overload switches in which the rupture of the circuit is effected in a body of oil.

752,236. ELECTRIC GENERATOR; Hans Liebreich, Boston, Mass. App. filed June 29, 1903. Means for demagnetizing the field at a proper time to prevent the retarding effect of continued cutting of the line of force in the field.

752,345. ELECTROMAGNET; James C. Keller and Otto F. Kadow, Cleveland, O. App. filed May 23, 1903. A ring-shaped magnet in two parts, one of which is hinged to the other, while their free ends in moving towards each other, move a lever to accomplish certain functions.

752,357. PROCESS OF ELECTRICALLY HEATING ARTICLES; Edgar F. Price, Niagara Falls, N. Y. App. filed Nov. 5, 1902. A process for baking carbon bars, in which the bars are alternated in an oven with material which is normally a poor conductor but which becomes a good conductor under heat. The current is first passed through the non-conductor which becomes gradually heated and communicates its heat to the carbon bars.

752,358. PROCESS OF HEATING ARTICLES BY ELECTRICITY; Edgar F. Price, Niagara Falls, N. Y. App. filed Nov. 5, 1902. A modification of the preceding invention.

752,374. AUTOMATIC CHECK DEVICE FOR TROLLEY CORDS; Seth F. Buckland, Springfield, Mass. App. filed April 22, 1903. A spring-drum and ratchet arrangement for retracting the trolley cord.

752,376. ELECTRIC BRUSH HOLDER; De Witt C. Cookingham, Cleveland, O. App. filed Oct. 15, 1903. Details of construction.

752,391. ELECTRIC MOTOR; Christian Fleischmann, Bloomfield, N. J. App. filed June 24, 1903. Commutation is shifted by rotating the field magnet instead of the brushes.

752,251. AUTOMATIC TELEPHONE SYSTEM; John K. Norstrom and John J. Brownrigg, Chicago, Ill. App. filed June 28, 1901.

752,405. TRANSFORMER; Charles B. McCurdy, Warren, O. App. filed April 24, 1902. Certain improvements in transformers intended for use in connection with a three-wire system.

752,408. ELECTRICAL APPARATUS FOR PRODUCING SOUND SIGNALS; Charles H. O'Brien, Augusta, Me. App. filed Nov. 1, 1902. A diaphragm is caused to produce a sound by the action of the core of an induction coil and of a permanent magnet inside of the core, the two combining to produce a loud sound which can be used for signaling purposes.

752,419. HIGH TENSION THERAPEUTIC ELECTRODE; Manuel R. Rodrigues, Brooklyn, N. Y. App. filed June 3, 1901. The electrode is a body of insulating material having the terminal of the conductor embedded in it to avoid the painful sensation of a direct application of the current.

752,431. AUTOMATIC SIGNALING APPARATUS FOR INCUBATORS OR HOTHOUSES; Horace B. Ault, Newmarket, Tenn. App. filed July 20, 1903. Details.

752,437. OVERHEAD TROLLEY GUIDE; Charles W. Burkehead, Madisonville, O. App. filed Aug. 16, 1902. A guiding fork constructed to perform its function whether the wheel is running forward or backward on the wire.

752,456. RECEPTACLE AND ATTACHMENT PLUG; Hubert Krantz, New York, N. Y. App. filed Oct. 24, 1903. Details.

752,460. FIRING MECHANISM FOR SHIPS' GUNS; Ludwig J. Mautner, Vienna, Austria-Hungary. App. filed June 4, 1903. An automatic firing device which depends for its action upon the incline of the ship with respect to the position of the object.

752,493. MOLDING CASE FOR USE IN ELECTROTYPING AND PROCESS OF MANUFACTURING SAME; William H. Welsb, Collingswood, N. J. App. filed Oct. 13, 1903. A molding case obtained by casting an impressionable composition, coating the said composition with flour of copper, forming an impression in the composition, then subjecting it to a black-leading machine and finally to an electrolytic bath.

752,501. TROLLEY HANGER; Montraville M. Wood, Schenectady, N. Y. App. filed Aug. 8, 1903. A cup-shaped nut that holds the clip in place, is provided with a locking device to prevent it from turning.

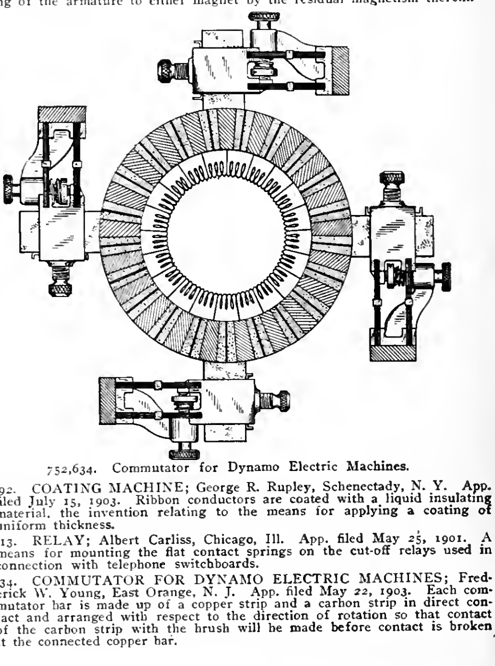
752,528. PROTECTIVE MEANS FOR ELECTRIC BOOSTERS; Maxwell W. Day, Schenectady, N. Y. App. filed July 6, 1903. The combination with a booster and its driving motor, of a circuit-breaker located in the main supplying both of them and having its tripping coil in the motor circuit only.

752,531. ELECTRIC SWITCH; Warren K. Dodge, Manhattan, Kan. App. filed Oct. 23, 1903. Details.

752,544. ELECTRICAL DEVICE FOR SHOCKING HORSES; James A. Giles, Elberton, Ga. App. filed Sept. 24, 1902. A magnet with a circuit extending to electrodes on the harness.

752,552. AUTOMATIC CIRCUIT-BREAKER; Edward M. Hewlett, Schenectady, N. Y. App. filed Nov. 28, 1898. Details.

752,590. MAGNETIC CLUTCH APPLICATION; John Riddell, Schenectady, N. Y. App. filed July 27, 1901. In a clutch of the kind described in the previous patent, this invention provides a device for preventing the sticking of the armature to either magnet by the residual magnetism therein.



752,634. Commutator for Dynamo Electric Machines.

752,592. COATING MACHINE; George R. Rupley, Schenectady, N. Y. App. filed July 15, 1903. Ribbon conductors are coated with a liquid insulating material, the invention relating to the means for applying a coating of uniform thickness.

752,613. RELAY; Albert Carliss, Chicago, Ill. App. filed May 25, 1901. A means for mounting the flat contact springs on the cut-off relays used in connection with telephone switchboards.

752,634. COMMUTATOR FOR DYNAMO ELECTRIC MACHINES; Frederick W. Young, East Orange, N. J. App. filed May 22, 1903. Each commutator bar is made up of a copper strip and a carbon strip in direct contact and arranged with respect to the direction of rotation so that contact of the carbon strip with the brush will be made before contact is broken at the connected copper bar.

Electrical World and Engineer

THE CONSOLIDATION OF "THE ELECTRICAL WORLD" AND "ELECTRICAL ENGINEER."

VOL. XLIII. NEW YORK, SATURDAY, MARCH 5, 1904. No. 10.

ELECTRICAL WORLD AND ENGINEER.

Published weekly by the

McGRAW PUBLISHING CO.

114 LIBERTY STREET, NEW YORK.

TELEPHONE CALL: 7605 CORTLANDT. CABLE ADDRESS: ELECTRICAL, NEW YORK.

EDITED BY T. C. MARTIN AND W. D. WEAVER.

CHICAGO OFFICE - - - - - - 1139 Monadnock Block.
PHILADELPHIA OFFICE - - - - - - 929 Chestnut Street.
EUROPEAN OFFICE, Hastings House, Norfolk St., Strand, London, Eng.

NOTICE TO READERS
WHO ARE NOT SUBSCRIBERS.

ELECTRICAL WORLD AND ENGINEER is not returnable from the newsdealer. If you desire to purchase the paper from a dealer it will be to your advantage to notify him that you will want it, in order to insure his having a copy for you. If you wish to receive the paper regularly, please send in your subscription so that we can mail it to you direct.

Single copies are 10 cents each. The 52 copies for the entire year cost $3.00 in advance. Please send remittance with your subscription order.

ELECTRICAL WORLD AND ENGINEER.

NOTICE TO ADVERTISERS.

Change in advertisements intended for a particular issue should reach the office of ELECTRICAL WORLD AND ENGINEER by 10 A. M. MONDAY of the week of issue. New advertisements can be received up to noon of Tuesday of the week of issue.

The first issue of each month is an export issue, having an extraordinarily large foreign circulation in addition to the regular domestic and foreign circulation of this paper.

TERMS OF SUBSCRIPTION.

United States, Canada or Mexico	Per year, $3.00
Foreign Countries, within the Postal Union	6.00
Great Britain and Ireland	25 shillings
Germany	25 marks
France	31 francs
Single copies	.10

Remittances for foreign subscriptions may be made through our European office. In requesting your address changed give OLD as well as new address.

Entered as second-class mail matter at the New York Post Office.

NEW YORK, SATURDAY, MARCH 5, 1904.

CONTENTS.

THE CAREER OF A TECHNICAL PAPER.

The relentless march of time necessarily brings with it anniversaries which serve as milestones in the history of institutions, as well as of men and nations, and it is a natural and appropriate thing that note should be taken of such occasions. These anniversary seasons and periods are not only enjoyable but useful, and even when sad may carry with them some lesson or stimulus. It sometimes happens that these memorial occasions are of interest chiefly to the person most directly concerned, but in the case of a journal, for example, whose sphere of activity and influence may be co-extensive with the boundaries of the art it represents, and even overpass them, it is believed that an anniversary such as that which is celebrated by ELECTRICAL WORLD AND ENGINEER this week is one of which other people would like to be reminded. In fact, the number of friends who have contributed reminiscences and words of congratulation to the present issue may be taken as an indication that the event is regarded as one constituting part of the history of electricity and its development in the United States; and proving that whatever good work the journal has done or has attempted to do in its thirty years of existence has not gone unrecognized by a generous and sympathetic public.

The record of this journal in its humble beginnings; its changes of name and habitat, its absorptions, amalgamations and consolidations; its notable growth and other aspects, is a fitting epitome or summary of the electrical art as a whole which it has sought to mirror and to foster. This journal began its career in 1874 as the *Operator,* founded as an organ of a very modest character for telegraphers, but it was no sooner started than it saw new opportunities in the coming developments of electricity, so that in 1876 the telephone was hardly invented before the *Operator* began to discuss it. In the same way it noted also the beginnings of electric lighting, and in the year 1882 published a series of articles on the subject which were recognized as doing a great deal to educate engineers and the public in the principles and adoption of the new illuminant. The year 1882 saw also the first issue of *The Electrician,* which seventeen years later, in another guise, was destined to be consolidated with the *Operator,* also under another name.

In January, 1883, the little telegraph journal became *The Operator and Electrical World,* but its growth throughout the earlier part of that year was so rapid it was realized that it would be better to make a further change, and on April 28 the current was subdivided and *The Electrical World* began its separate career. The next year, 1884, witnessed the electrical exhibition in Philadelphia and the electrical congress there, both events giving a great stimulus to the art, and the same year saw also the foundation of the American Institute of Electrical Engineers, the organizing circular for which was issued by the editors, and from the offices, of *The Electrical World.* At that exhibition also a great stimulus was given to the use of electricity in printing, by the use of an electric motor there, with which some 70,000 copies of the paper were printed. In 1888 *The Electrician* became *The Electrical Engineer,* but remained a monthly until 1890, which witnessed its first weekly issue. In 1894 *The Electrical World,* which had been published in the familiar old folio style, still favored by some weekly journals, adopted its present quarto style, which has been found much more convenient by readers and which had always characterized *The Electrician.* A period of absorption and consolidation now set in, the *Electric Railway Gazette* being absorbed in 1896, while in 1899 the consolidation took place of *The Electrical World* and *The Electrical Engineer,* the change of ownership and management being accompanied by the adoption of the title Electrical World and Engineer, under which for the past five years the journal has been conducted.

This in brief, and not touching on many points of interest, is the record of the journal as a publication and business. A word or two may be added with regard to the personnel of the institution, omitting those at present connected with it. On the business side and also in regard to a great deal of the editorial work, the papers which have gone to make up the present journal enjoyed the energy, activity and sound business acumen of such men as Messrs. W. J. Johnston, G. M. Phelps, C. E. Stump and F. R. Colvin. The editorial staff, impressing upon the various journals the stamp of high ability, sound judgment, strict impartialty and the conscientious discharge of journalistic duty, has included such men as F. L. Pope, C. O. Mailloux, Louis Bell, C. J. H. Woodbury, Joseph Wetzler, J. E. Woodbridge, R. W. Pope, N. S. Keith, H. W. Frye, G. H. Stockbridge, C. T. Rittenhouse and C. T. Child. Several of these men, some of whom have passed away, distinguished themselves not only by editorial skill, but by accomplishment in other fields of electrical endeavor, and their work constitutes in large measure whatever of strength and importance this publication may now possess as the recognized leader in electrical journalism.

Thirty years is perhaps a long time in the life of a journal, especially in the technical field, but is not a particularly long period in any art. Electricity, however, is unquestionably quite young as compared with other branches of science and industry, and as one looks back over the past thirty years it is hard to believe that any period of equal duration could be more closely crowded with glorious life and achievement than has been the era 1874-1904. But should coming years hold in them potentialities and accomplishments in electricity greater than any that have been known in the past, it is hoped and believed that the Electrical World and Engineer and those who conduct it will be found adequate and faithful to every demand that may be made upon them in the production of a fearless, progressive, authoritative and independent journal.

Side Lights of History.

In preparing to issue an anniversary number celebrating the close of its thirty years of continuous existence and beginning its fourth decade, the Electrical World and Engineer believed that while it was unnecessary and superfluous to recapitulate seriously the whole marvelous record of the period between 1874 and 1904, it might do something that would be of lasting value and interest by giving space to the ideas and reminiscences of some of the men who had been leaders as thinkers and workers during the time named. The events connected with the evolution and development of modern telegraphy, the telephone, the arc light, the incandescent lamp, the electric motor, the electric railway, electric lighting, electric heating and other branches, are pretty familiar to-day and may be found in the books. But there is still unwritten a great deal of personal history and reminiscence which must in days to come constitute for the historian and the student much of the material that will be most valuable in re-creating the actual atmosphere and events surrounding those great inventions at the time of their birth and during their struggles for foothold and supremacy.

The editors of this journal deem themselves fortunate to have been able to bring together within the pages of this present issue so large a volume of personal recollections and data belonging in the class which the French call happily *memoirs pour servir,* and having that charm and fascination which must always attach to autobiography. It will be seen that these articles cover all the great inventions of the period and that many of them present facts under new illumination. It might indeed be urged that a single issue embracing the contributions of such well-known captains as Edison, Tesla, Sprague, Coffin, Griffin, Kennelly, Bell, Anthony—to name but a few—has by that very reason a unique permanent value. Such articles are, indeed, side lights of history, but they are something more, especially when thus brought together in celebration of a specific anniversary in the art which has seen such wonderful and unparalleled expansion during the past thirty years. The Electrical World and Engineer is proud to present the contributions of these friends, whose presence in its pages at such a time it regards as a mark of good will and esteem; and it takes this opportunity of acknowledging its deep appreciation, as well as of expressing its sense that it is thus pledged to even greater effort in the future.

The Portrait Supplement.

In connection with its present anniversary issue, the Electrical World and Engineer has thought that it might be interesting to give in one group the portraits of some typical leaders in the thirty years of American electrical development included in its own lifetime, namely, 1874 to 1904. This period misses narrowly the creators of the telegraphic era in America, but includes the pioneers in every other branch, as well as one or two men who may be regarded as bridging the gap between the old world and the new of electrical development. It is thought, therefore, that the Supplement to this issue will be found of more than general interest, and that while it is likely to be preserved for its intrinsic value, it will also serve to suggest a few timely thoughts as to the scope and variety of the modern science and its applications. Electricity has laid hands upon so many departments of life and has affected so many branches of industry, finance and commerce, it is no longer possible to find its leaders or its heroes in one separate class or group of men. The field has already become so wide and so large, it is only possible in such a supplement as is here presented to include leaders who are typical and alongside whom might be placed others with propriety, pre-eminent in their own group or class, were it not for the claims which other categories have for consideration and inclusion.

In the field of pure science one would certainly select and name first of all Prof. Rowland, honored abroad even more than in his own country, yet even he did not disdain to work on the utilitarian side of electricity and to take out patents. With him might well be classed Dr. Pupin as representing the present physical and educational sides of electricity, himself also an inventor and patentee of no mean order. As between the old school of telegraphy and the modern school of electrical engineering there would seem to be little in common, for Edison is the only connecting link between Gray and Farmer, of the earlier period, unless we take into account F. L. Pope, who doubtless had higher claims as the typical electrical journalist of the last century. Farmer again belongs not only to the telegraphic stratum or branch, but is connected with the new dynamo days through Weston, who also exemplifies the evolution of the modern electric lighting and power art out of the prior electroplating practice. It is true, of course, that in a broad sense the telephonic group of inventors ought to be considered as lineal descendants of the telegraphers, but there is no question that such men as Bell and Blake have dealt with an altogether different set of problems from those which confronted Morse and House; and that in the telephonic engineering done by Carty and his colleagues there is no parallel whatsoever to be found in any other branch of electrical engineering.

It is the electric lighting period which introduces us to a great group of notable men and brings to the front the large manufacturers typified by such brilliant examples as Coffin and Westinghouse, the first of whom, however, has devoted his energies entirely to the financial development and industrial exploitation of the art, while Westinghouse has further claims to consideration as a designer and inventor. Here again he links with Wheeler as a manufacturer, engineer and inventor, while Wheeler has the further distinction of laying the foundations broadly and liberally of the Institute Library and of thus setting in motion the forces which have of late brought electrical engineering in closer touch with the older professions than ever before. In the electric lighting field, Edison at once comes to the front again as he does in those of telegraphy and telephony; while shoulder to shoulder with him stand such masters as Brush, Thomson and Wood, the work of each man being that of a successful pioneer. Edison again forms a starting point in regard to the electric railway art, going back also to Farmer and embracing men whose names will be even more widely known in the future than that are to-day, such as Sprague and Van Depoele. In the manipulation, transmission and distribution of current beginning with this modern period of electric light and power, are associated again most intimately several who have already been mentioned and others in the group, such as Stanley, Steinmetz, Scott and Shallenberger, the last of whom indeed might well be considered along with Weston, Thomson and Edison in the invention and perfection of measuring instruments. Quite in a class by himself from his advanced and daring work and predictions as to the future, is Tesla, although he ranks high already chiefly through his successful efforts to render alternating current available for power and transmission purposes. Going back to the earliest days of electrical development on the chemical line of advance, one must include such men as Farmer, Edison and Weston, but these would not be chosen as typical of the latest period; and it is for this reason that in this group places of honor are given to such men as Hall, Cowles, Acheson and Bradley, although the last two named have further claims to consideration; one as a pioneer in the electric lighting field, and the other as a most fertile and progressive inventor of dynamo electric apparatus.

But even when all this has been said, and a fair ascription of credit has been made to these men and the colleagues or branches whom they represent, a great deal of work is left untouched of equal value and importance in rounding out the availability of electricity to the public. It is for this reason that portraits are presented of such men as Leonard, inventor and engineer in many fields, and particularly prominent in that of resistances and electric heating. Other vital lines of work are typified by Pearson as a designer of central power plants; Insull, not only a manufacturer but a typical central station manager supplying current in enormous volume for every public necessity; or Kellogg, also an inventor, but conspicuous chiefly as a manufacturer and as a typical figure in the wonderful independent telephone movement which has been one of the leading electrical features of the present century, and has affected very other branch of electrical industry. Last but not least, comes Fish, typical in every way of the prominent part played by the legal fraternity in electrical development from its very beginning, and himself one who has contested more causes of tremendous importance in the electrical field than any other man living or dead, while again necessitating consideration as the business head of the greatest telephonic system in the world.

It is easy to imagine the substitution of other men for some of those whose portraits are presented in this Supplement, especially if undue weight is given to the claims of some particular field or branch of electrical industry over the others. The attempt has been made, however, to select men who, individually and collectively, may be taken to stand for the sciences and arts to which they have devoted their lives and whom their associates agree in honoring as typical leaders in the past thirty years of American electrical development.

A Campaign of Publicity.

It always seemed to us, as well as to a great many other people, that the advertising pages of any paper are one of its most interesting and instructive features; and this idea is particularly true with regard to technical and trade papers from the fact that so much apparatus is therein illustrated and described. The manufacturer in his own space in the advertising columns is practically at liberty to show what he likes and say what he likes with regard to his apparatus, and very often he first puts on view there with all its claims the device or appliance for which superiority over everything else in the same field is asserted. It thus happens that the advertising pages of such a journal as the Electrical World and Engineer throughout a term of thirty years and such a period as that which it celebrates in this issue, present an invaluable picture of the industrial development of the time, one that could not possibly be overlooked or neglected by any person who would later seek to make himself acquainted with what had been done in the industry. From the first advertisement inserted in the pages of the old *Operator* down to the current issue of its lineal successor, the Electrical World and Engineer, with its 196 pages of advertising in the single issue—high-water mark in electrical advertising in America—the stream of history is unbroken, and all the points of advance are sharply and strikingly defined. We would not like to say that if the reading pages were omitted the art could still be reconstituted from these advertising pages, for that would overlook the great development of engineering theory and scientific research out of which inventions grow; but it is nevertheless a statement capable of being sustained that every great outburst of inventive activity has made a clear and indelible imprint in those advertisements.

This is one aspect of the question of advertising, but there is another which is of vital importance to the manufacturer, and that is the success which should attend his efforts to reach the public and to market his goods. We must therefore take it to be a conceded fact that the notable extent to which the advertising pages of this journal have been used as a means of influencing trade has been found justified by those who have spent their money so liberally to secure publicity. And from the past we would derive a cheerful augury as to the future, for it is to-day better understood than it ever was at any time during the last thirty years that publicity must be sought scientifically, persistently and liberally. Each new development in electricity has required means for reaching the attention of a new set of customers, but the great broadening out of the area of contact with the public thus necessitated has, we believe, found this journal ready for the test and equal to it. In fact, it is no presumption to say that in some respects and very often this journal has had to advocate causes that appeared like forlorn hopes, and to keep hammering away at developments which it seemed would never "arrive." But as Mr. Ayer has pointed out in his interesting article, it has been strange how few of the electrical inventions up to date have failed to justify the hopes of their partisans and promoters, and this we feel must be attributed in very large measure to the publicity and advertising that has been secured.

If we were to want a justification of our point of view we could desire no better proof than the article which Mr. Arthur Warren has recently contributed to one of the New York dailies. This gentleman, as is well known, was for some years past at the head of the advertising bureau of one of the largest electrical corporations in this country, and his whole article is an insistence upon the necessity of advertising and the remarkable gains which follow judicious expenditures. As he says, "There was a time when good wine needed no bush; when great industrial concerns scorned publicity; but competition has changed the conditions in the last half-dozen years." Every one familiar with the field of industrial development must recognize the truth of this, but it seems to us that very few men yet, in the electrical field, realize how largely their business could be built up beyond its present figures by aggressive campaigns of publicity. As Mr. W. F. White points out elsewhere in his suggestive remarks on the growth of the sale of current, the gross receipts from the use of electrical energy for all purposes do not exceed at the most $2 per capita per annum in our largest cities, and he insists that such figures can be increased four or five fold. We believe with him that they can, but it will not be done without methods of publicity far exceeding in boldness and vigor anything yet witnessed by ourselves or our readers.

The Loading of Telephone Circuits.

We give this week an account of the most recent work accomplished in the direction of improving and extending telephonic communication by the aid of the Pupin system of inductive loading of telephone circuits. The work is evidently in steady progress. It is clear, however, that in spite of all benefits thus far derived, or immediately in sight, we must not expect to talk from New York to London, or to Brisbane, Australia, just yet. Every year makes the need of loaded conductors more apparent. The cities are building out into the country and extending their limits. They insist, and the very necessities of construction likewise insist, that the telephone wires shall go underground. As soon as the wires go underground the added resistance and capacity of the cables greatly reduce the volume and clearness of the telephonically-transmitted speech. A few miles of underground cable are harder to talk through than a thousand-mile air line from New York to Chicago. The loading of underground circuits comes to the rescue under these circumstances, and mitigates the difficulties with the stretches of cable in the limits of terminal cities. No doubt it will some day be necessary to load all underground telephone wires, as a matter of standard practice and general necessity.

Electric Railway Growth.

It is an extraordinary fact, for which we have never seen any adequate or satisfactory explanation, that the electric railway—the latest comer amongst the great electrotechnical industries which grew up during the past century—has far exceeded in importance and magnitude of investment the others which preceded it. It is also a singular fact still remaining to be elucidated that the industries have been successively larger in the order of their creation and progression, telephony being in excess of telegraphy, electric lighting larger than either of them, and the electric railway the biggest of the lot. In fact, according to the authentic figures now available, the electric railway with a capital investment of $2,500,000,000 is more than equal to all its predecessors put together, which at the most could hardly be set down for much beyond $1.750,000,000—itself no slight item.

Our present issue contains amongst its memorial and reminiscent articles, several dealing with the crude and humble beginnings of the electric railway industry in the United States now represented by such an enormous aggregate of capital. We are able to present from those who actively participated in the stirring events of the 80's, very interesting stories as to what was done on the early Daft, Van Depoele, Sprague, Bentley-Knight and other pioneer roads of the period. We are sure that anyone who reads those articles, as all doubtless will, would hardly believe it unless they knew it to be so, that from such unpromising commencements has been built up the art which at this moment has begun to claim also for its own the vast domain that has previously acknowledged only the sceptre of steam. The figures, for example, which General Griffin, himself one of the pioneers, gives in his article, are simply astounding, for the same man who made the first governmental report on the subject is able also to tell quietly, almost as a matter of course, how from 100 cars electrically equipped in '87, a total of 55,000 cars electrically equipped has been reached in 1903; while the outfit per car has advanced from 10 hp up to 2,250 hp each for the electric locomotives on the New York Central system.

It is interesting also that our present issue should contain two such unusual articles as that by Mr. Frank J. Sprague on his own work and the outlook for the future, and that on the Ward Leonard pioneer work, on single-phase traction, which now beckons so hopefully as one of the means by which the heavier work ahead has to be done. The two points of view presented in these two articles are most striking and interesting. To us they do not suggest the idea of conflict at all, but rather proclaim the flexibility and resourcefulness of electricity with its two forms of current, the direct and the alternating; one of which has already done such magnificent work, and the other of which justifies such sanguine expectations as to its accomplishments in the near future. The discussion by Mr. Sprague of the features of advantage and utility in connection with the direct current is singularly timely and most felicitously put, and we know that it will enjoy the attention it so well deserves.

THE NEWER ARTS.

The contents of the present commemorative issue of this journal deal largely with the electrical arts now in prosperous existence and with the stages by which they have successively been brought into being. The very number and magnitude of these industries created during the past thirty years make us wonder a little as to what may be the newer arts and industries which the next thirty years will see in the electrical field. Prophecy is rather dangerous and difficult in regard to electricity where so many things crop up unexpectedly, but there are those who are willing to try their hand, as for example, Mr. Tesla, whose article alone would give distinction to our current number, by its bold vaticinations. If all he says and believes were to come true, there would indeed be a crop of new arts to stagger the world with.

Aside from prophecy, however, and the results that might be reasonably expected from such progressive work as that with radium, it would seem that there is reason for hope attending developments within the immediate range of practicality. Wireless telegraphy is certainly proving itself capable of becoming a great industry, and opposed to that we have the bright promise of long-distance and submarine telephony. In the domain of heavy work there is every reason to believe that telpherage may build up an industry equalling in the actual amount of hard work done whatever is now accomplished in street railways. Electric heating is also showing itself capable of indefinite extension, as evidenced by the remarkable plant which we described recently in the Government Printing Office at Washington. There would also seem to be hope in electric canal haulage, and certainly some in the transportation of mail and other matter through tubes in city streets and from one part to another of our huge modern office buildings and factories. These and other fields to occupy, to say nothing of the conversion of the steam railroads, stretch before the eager electrical engineer. Particularly in electrochemistry and electrometallurgy, as pointed out in the admirable article by Dr. Roeber, may we expect to see new and valuable arts arise. But even if no new developments impended, the growth of wire telegraphy, of telephony, of electric lighting and power, and of street traction, as well as of other well-established arts, would provide abundant occupation for every man now enlisted under the electrical banner.

THE LIGHTING OF THE FUTURE.

It is with no prophetic instinct that we would seek to forecast the immediate future of the art which has won so great a place in the thirty years past, nor do we propose to indulge in iridescent dreams of what may come to pass if the hopes of inventors are fully realized. We wish merely to point out some of the salient facts that confront us as auguries of work for the next generation. To view the situation soberly, neither electric lighting nor any other single form of artificial illumination touches deeply the roots of human life and industry. The world would wag on in about the same old fashion if petroleum or coal gas, acetylene or electric light were forgotten. The abolition of any one of these would be, save for those immediately concerned in its production, a transition phase of fashion, and bring us back to early dinner hours. Of all known illuminants, electric light is easily the first from a hygienic standpoint, since the light is produced without sensible combustion. This virtue and its excellent color value conspire to give it a very strong hold on public favor, but as regards the former characteristic, few people are willing to pay, when in good health, any considerable price for hygienic conditions, and as regards the latter, it is fully equalled, for instance, by acetylene. In the last resort, therefore, the battle of illuminants resolves itself into a contest for economy, modified only by the dictates of fashion and external appearances. At the present time, electric lighting has the upper hand of its competitors, but it can retain it only by constant fighting. It has, of course, certain strongholds from which it cannot easily be driven, although the open field as a whole is for anybody's winning.

At the present time the electric arc is by a very perceptible amount the cheapest all-around illuminant, and this fact is the strongest ally of incandescent lighting. For, while cheap gas in mantle burners can undoubtedly beat out the incandescent lamp, candle for candle, in mere cost, it cannot meet the arc on even terms, and if the consumer is deaf to all arguments based on hygiene and color blind to boot, the central station still holds a trump card in the arc. The intensing mantle burners in their various forms can beat out the arc indoors, so far as price is concerned, but are at a disadvantage out-of-doors, and require some species of local plant which works to their disadvantage in the matter of convenience. It is safe, then, to say that the electric arc will keep a strong position among illuminants for a long time to come, and that it will be steadily improved along lines which are already blazed out. It is in the field of incandescent lighting that the fiercest battle will rage. In spite of all the experimental work of the past few years, the glow lamp retains its supremacy, and its reign is not yet even seriously threatened. Until the Nernst lamp runs without attention, and the vapor lamps cease to be green, these, the most promising recent innovations, will be seriously handicapped. Evidence goes to show that no amount of talking will persuade the general public that green is a desirable or becoming color for lights—or make it so. If argument could blind the eye to that uncanny shade, the mantle burner would long since have had the glow lamp "in chancery" in spite of every effort at defense. Let the vapor lamp once escape from the color difficulty, and it will immediately assume a most commanding position in the art, even if it should only be available in rather large units of great intrinsic brilliancy.

Two things we need in electric lighting for the immediate future. One is a lamp of moderate power, moderate intrinsic brilliancy, good color and high economy to replace or supplement the present glow lamp. The other is a very efficient lamp of almost any power and brilliancy, with plenty of red and yellow in its spectrum, and capable of operating when fully enclosed, and practically without attention. The first form of lamp has its obvious uses laid out in advance. The second would be almost equally valuable to the art, and could be utilized for indirect lighting with the greatest advantage. If the arcs with composite carbons could only be enclosed and run without attention, they would fill the bill exactly. But no form of arc yet devised can advantageously be employed as a concealed illuminant, and, however efficient, it is easily beaten out by the glow lamp for interior illumination. Almost any kind of illuminant will answer out-of-doors provided it does not require too much attention, but for the regular work of interior lighting the incandescent lamp fully holds its own, inefficient as it relatively is. Which of the suggested improved lights is likely to appear first, no one can tell; perhaps both may come together. The chances seem a little better for the first named than for a light of high power; and the futile efforts which have thus far failed to obtain either are evidence enough of the difficulty of the problem. Lacking these improvements, the best hopes of electric lighting lie in the skilful use of the illuminants that are now available, in a careful adaptation of means to ends, and in a realization that illumination is not a haphazard business where all the light that can be paid for is the proper amount to use. On the contrary, light improperly employed is not only useless but harmful, and one light well placed is better than two misplaced. If one can make ten common glow lamps do the work of fifteen as now used, he has scored as great a success as if he had installed a new form of two-watt lamp. The final test of lighting is light.

Civil Engineers to Stay Out.

The American Society of Civil Engineers, as the result of its ballot vote taken recently and canvassed this week, has decided not to join with the other national engineering bodies of the country in accepting Mr. Andrew Carnegie's gift of $1,500,000 to be devoted to creating a magnificent engineering home and center in New York City. The vote was decided by 1,134 against 662 for acceptance, or a majority of 472 against the plan. The Society has a membership of about 2,500, from which it would appear that no fewer than 700 members abstained from voting, or were indifferent to the matter.

It will be remembered by our readers that as an immediate result of the library dinner of the American Institute of Electrical Engineers held in February last year, Mr. Carnegie gave $1,000,000 to the four principal national engineering societies, namely, the American Society of Civil Engineers, the American Society of Mechanical Engineers, the American Institute of Mining Engineers and the American Institute of Electrical Engineers, as well as to the Engineers' Club, a social organization including members from all bodies: this money to be devoted to the erection of a building or buildings where all these bodies could be adequately housed. The Engineers' Club already had land on West Fortieth Street facing the new Lenox Library, and Mr. Carnegie immediately proceeded, therefore, to acquire land on Thirty-ninth Street so as to enable the proposed building for the engineering societies and the new building of the club to be placed in convenient juxtaposition. Up to the present time he has spent in the vicinity of $600,000 in thus acquiring land for the benefit of the four engineering bodies named, three of which as well as the Engineers' Club, have already accepted Mr. Carnegie's gift.

A reconsideration of the plans and the fact that if the Civil Engineers came in quarters would be needed for not less than 12,000 professional men and for societies all of which are growing rapidly, determined Mr. Carnegie to increase his generous offer; and with characteristic promptness and liberality he added half-a-million dollars to the sum which he had originally designated, intimating as he did so that his great aim and ideal in doing this was to foster fellowship and promote union and harmony amongst the engineering professions; so that all while maintaining their individuality could work together for the common good. As will be seen, however, the Civil Engineers, who already have a house of their own on West Fifty-seventh Street, have now decided to stay there alone and isolated, although as their recent annual meeting proved, it is much too small for their purposes, so that the very meeting at which the ballot vote was decided upon had to be held in the Carnegie Lyceum adjoining.

Our readers are well aware of the fact that immediately following the announcement of Mr. Carnegie's gift a conference committee of fifteen was formed with three members from each of the five bodies interested. It would appear from this vote that the delegates of the Civil Engineers are no longer authorized to participate in the proceedings of the conference committee. Mr. Carnegie and the three societies, which have already voted to accept his gift, and which, with the Engineers' Club, number some 8,000 or 9,000 members, will possibly have to change their plans and adjust them to the conditions which have arisen from this action of the Civil Engineers. It is needless to say that the attitude of the members of the Civil Engineers who voted against what are regarded as broad, common interests is viewed with deep regret by electrical engineers, who looked forward eagerly to closer co-operation with the Civils, but who find some consolation, however, in the fact that after all less than half the members of the society recorded an unfavorable vote. The results of this action will be followed with the greatest interest by engineers all over the world.

In the meantime, the American Institute of Electrical Engineers, realizing that whatever might be the course of events, it would have to call upon the generosity of its members in order to be able to assume new liabilities and larger responsibilities in safety, has, with its wonted vigor, lost no time in getting itself into a position where it could command resources of its own at least equal to those of any other society. During the past few weeks, therefore, its Land, Building Fund and Endowment Committee has gone to work, and from perhaps not more than a hundred of its members it has already secured donations and pledges of $40,000. When it is considered that the membership is 3,000, it will be seen that the committee is warranted in its hope of raising at least $150,000 from the members; and not less than $50,000 to $100,000 is expected from the corporations and manufacturers in the industry benefitted by the Institute work. The Institute thus fairly expects to be in a financial position equal to that of any other kindred society, and adequate to the purchase of land for any kind of a building Mr. Carnegie may put on it.

The Chicago "Tech." Dinner.

The Northwestern Alumni of the Massachusetts Institute of Technology held a dinner February 27 at Chicago, which proved to be an affair of considerable electrical interest. Mr. V. R. Lansingh, the well-known illuminating engineer of Chicago, who is secretary of the alumni association and made the preparations, had a surprise in store. When the guests entered the banquet room at the University Club they found it illuminated with six 750-cp Cooper Hewitt mercury vapor lamps. This was the first opportunity the majority of those present had had of testing the qualities of the mercury vapor lamp for general interior illumination. The lamps were turned off during dinner, but were turned on again by way of introduction to the after dinner remarks of Professor W. E. Goldsborough, who told of some of the new things in the electrical line to be at the coming St. Louis World's Fair. The mercury vapor lamp in several forms, he said, was to be one of the new features. He spoke of some decorative lighting in colored lights which would be different from the decorative lighting of previous expositions. Wireless telephony, he said, was another new feature that would probably be shown, and several of the new single-phase alternating-current railway motors would be on hand.

Reception Committee for the Congress.

President Bion J. Arnold, of the American Institute of Electrical Engineers, has appointed the following general reception committee for the International Electrical Congress this year: John W. Lieb, Jr., chairman, 55 Duane street, N. Y.; Calvin W. Rice, vice-chairman, 348 Central Park West, N. Y.; E. G. Acheson, E. K. Adams, William A. Anthony, A. H. Armstrong, J. C. Barclay, Alex. Graham Bell, Louis Bell, Charles S. Bradley, N. F. Brady, C. F. Brush, H. W. Buck, George Bullock, H. S. Carhart, J. J. Carty, C. A. Coffin, C. D. Crandall, F. B. Crocker, H. L. Doherty, Alex. Dow, Louis Duncan, Gano S. Dunn, Thomas A. Edison, Charles L. Edgar, W. C. L. Eglin, R. A. Fessenden, S. D. Field, Frederick P. Fish, B. Gherardi, W. E. Goldsborough, Hammond V. Hayes, Carl Hering, Peter Cooper Hewitt, J. W. Howell, C. R. Huntley, Samuel Insull, D. C. Jackson, William J. Jenks, Francis W. Jones, John F. Kelly, A. E. Kennelly, W. A. Kreidler, H. Ward Leonard, Herbert Lloyd, T. D. Lockwood, John Martin, T. C. Martin, J. H. McGraw, E. L. Nichols, R. B. Owens, F. S. Pearson, W. A. Pearson, F. A. C. Perrine, Ralph W. Pope, W. V. N. Powelson, Charles W. Price, M. I. Pupin, Samuel Reber, E. W. Rice, Jr., A. L. Riker, E. B. Rosa, Charles F. Scott, Samuel Sheldon, Frank J. Sprague, William Stanley, C. P. Steinmetz, L. B. Stillwell, H. G. Stott, F. H. Taylor, Charles A. Terry, Nikola Tesla, Elihu Thomson, Calvert Townley, W. D. Weaver, George Westinghouse, Edward Weston, Schuyler S. Wheeler, J. G. White, W. F. White.

Coming Electrical Meetings in Chicago.

The electrical section of the Western Society of Engineers (formerly the Chicago Electrical Association) will hold a meeting March 18 at its rooms in the Monadnock Building, for the discussion of the "Electrical Opportunities in Chicago." George A. Damon, who will be the leader of this discussion, has sent out inquiries for reports from 100 of the best-known young electrical men of the city, inquiring as to education, training, opinions as to what constitutes the best preparation for an electrical career, and other matters throwing light on the subject. Mr. Damon has received replies from a large per cent. of those from whom this information was asked, which would indicate that the subject is one of general interest and one which will be productive of an interesting meeting. The Chicago branch of the American Institute of Electrical Engineers will have a meeting for the discussion of the single-phase alternating-current railway motor on March 8, at the rooms of the Western Society of Engineers.

Electric Lighting in the City of Benjamin Franklin.

By W. C. L. EGLIN.

FIG. 1.—STACK 275 FT. HIGH.

THE city of Philadelphia comprises an area of over 129 square miles, and the demand for current comes from all quarters of the city. Formerly, there were 27 companies with 18 different operating companies distributed throughout the city and suburbs, each of the companies operating on an entirely separate and independent basis by reason of its franchise, and thus preventing a consolidation of organization and operation similar to other large cities. The distribution of current by these various companies included practically all of the methods used commercially, viz.: direct current of 500-volt two-wire, 110-volt two-wire, and 220-volt three-wire systems; also single-phase alternating current, two-phase alternating current, and three-phase alternating current, with frequencies of 60, 66, 125 and 133 cycles. The voltages of the alternating-current feeders were 1,000 to 1,200 and 2,000 to 2,400 volts. The total number of consumers of these various companies was over 13,700, using 13,973 series arc lamps, 3,758 incandescent lamps, both direct current and alternating current, 16,000 hp in motors, and 494,000 incandescent lamps. The total equivalent connected load in 16-cp lamps was 878,000. The yearly kw-hours manufactured at these various stations were 59,405,970, divided as follows: Incandescent and power, 35,081,545; arc, 24,324,425. It was such a system that had to be unified and harmonized.

In the consolidation of a number of electric lighting and power properties, the first essential is a uniformity in the supply of current to the various consumers. Conditions existing in Philadelphia were similar to those in other large cities in which are located a number of small plants, some supplying alternating current and some direct current—those supplying alternating current having a voltage differing somewhat from the latter. Before, therefore, effectual consolidation could be made of the operation of these plants, attention was given to the distributing system; and after a careful study of the situation it was decided to adopt the two-phase 60-cycle alternating-current distributing system for most of the territory, and the direct-current, 220-volt, three-wire system for the principal business section of the city. This simplified the generating station as it required only one type of generator to supply directly all of the alternating current, and indirectly the direct current by means of high voltage alternating-current motors and 300-volt direct-current generators.

The entire distributing system was reconstructed so as to obtain a uniform primary and secondary distribution, and change the single-phase to two-phase circuits. All primary circuits were arranged for voltages ranging from 2,200 to 2,400 volts, and secondary, from 110 to 120 volts. Tie lines were installed between the various distributing centers, these tie lines being operated at 5,500 volts, which is the voltage of the generating station.

After the completion of the plans for the distributing system, a careful survey was made of the property on both the Delaware and Schuylkill Rivers to obtain a site for the main generating station. After examination of the properties obtainable, preliminary plans were made showing the ultimate capacity to be obtained on the properties. These plans were submitted to Mr. John T. Windrim of the firm of James H. Windrim, Architect, Philadelphia, Pa., who prepared the plans of the first section of the building. In selecting the site for the main generating station it was essential that enough ground be obtained to admit of an increase of at least ten times the first necessary equipment, so as to take care of any increase in capacity required for the large growth of the business during a period of years.

The site finally selected is, for many reasons, probably ideal. The total area is about nine acres, extending from the Schuylkill River front a distance of 1,304 ft. without being divided by streets. The actual distance from the central station to the center of the load district is about three miles. This property is bounded on the one side by the Pennsylvania Railroad and on another by the Baltimore & Ohio Railroad, and on the other side by Christian Street, a broad and well-paved street.

For the reasons above mentioned, it was decided to design the station on a sectional plan in order that it could be extended in one direction to the end of the building lot, each lineal foot of station giving a proportionate increase of switchboard, engine room, boiler room and auxiliary capacity. This necessitated that all of the apparatus be laid out in parallel lines, and the crossing or mixing of various classes of apparatus prevented by careful attention to details.

The first section of the building was located 360 ft. from the river in order to admit of an arrangement of coal storage at both ends of the complete plant. Fig 8 shows the survey plan of the property. It will be seen that this property is somewhat triangular, and that the width of the property increases eastward. The first section of the building was naturally located nearest the river.

The generating station consists of two buildings, one a boiler room and the other an engine room arranged with a number of mezzanine floors for switchboard galleries. The smoke-stack was placed outside of the building, first, to avoid taking up space in the building required for boiler purposes, and, second, the space was available outside and could be utilized to no better advantage.

The first work was arranging the foundations of the building, and the intake and discharge water conduits for condensing purposes. It was decided to arrange the intake and discharge conduits triangularly and construct them of concrete which would fulfill the function of foundations for the division wall between the engine room and the boiler room. The reasons for establishing this location was that water is required in both the engine and boiler-room

FIG. 2.—GENERAL VIEW OF CHRISTIAN STREET STATION, PHILADELPHIA.

buildings, and connections could readily be made to both sides of this conduit. The placing of the conduit in any other location would necessitate carrying the foundation for the columns of the building on either side down to a lower depth, thus increasing the cost. The arrangement of the conduits permitted of the desired capacity with minimum depth of excavation. The two lower intake conduits are each 7 ft. in diameter and joined with cross-connections of 4 ft. at frequent intervals. The discharge conduit is elliptically shaped, being 12 ft. in height by 8 ft. wide. Connections to the intake conduit are made by walls so that the intake pipes can be dropped down and be continuously submerged. The top of this conduit was entirely covered with 20-in. I-beams; and at the points where the columns rest, additional I-beams were placed across those upon which the bolsters rest, so that the load was distributed uniformly over the entire length of the conduit.

On account of the elevation of the ground towards the east, it was decided to make the engine room floor at the street level towards the middle section of the building, so that in the first section of the building there would be no basement, the basement being on the ground level about 6 ft. above high water.

It was decided to install as a unit generator the largest size to be obtained commercially, although at first a unit of one-half size was installed so as to operate economically at the light loads during the period of the growth of the load on this section. For these reasons 5,000-kw units were decided upon as the standard, and 2,000-kw units were installed as the half unit. Both of these units have an overload capacity of 50 per cent. for two hours.

The General Electric generators are revolving field, two-phase, 6,000 volts, excitation being provided by motor-generator sets. The motors, which are of the induction type, are wound for 6,000 volts, two-phase, the direct-current generator being wound for 300 volts.

A small steam exciter set is used in the event of the station being unable to obtain current from tie lines when starting up. These exciters are placed on the engine-room floor. On the first mezzanine floor are placed the direct-current switchboards for exciters, the oil switches, and the series and potential transformers. On the second mezzanine floor are the reserve oil switches, one of which is always in series with the switch on the floor below, and is also used as a selector switch for each of the bus-bars, the bus-bars being arranged in separate concrete compartments on the upper mezzanine floors, and the controlling board being located on the second mezzanine floor.

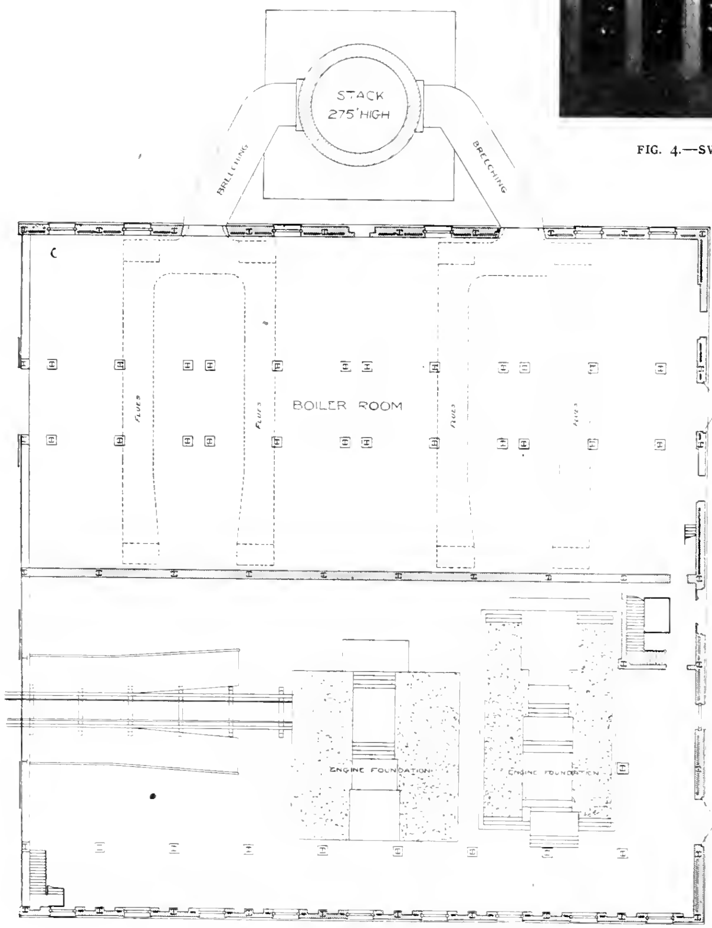


FIG. 3.—BASEMENT PLAN OF POWER HOUSE.

The boiler-house building consists of an arrangement for double-decked boilers with coal storage above the boilers and a common ash floor for both floors of boilers. The basement or ground floor is arranged to receive all of the ashes, each boiler being provided with a cast-iron sectional ash pit, and connections can be made between the combustion chamber and the ash pit for the ready removal of refuse material. On the side adjoining the engine room is situated a pump room in which are located the tank, pumps, boiler feed pumps and feed water heaters. The basement has a height of 18 ft., which admits of the use of almost any type of auxiliary apparatus without crowding. The flues of the first boiler room floor also pass through the basement to connect with the chimney, thus leaving the boiler room clear of any obstructions.

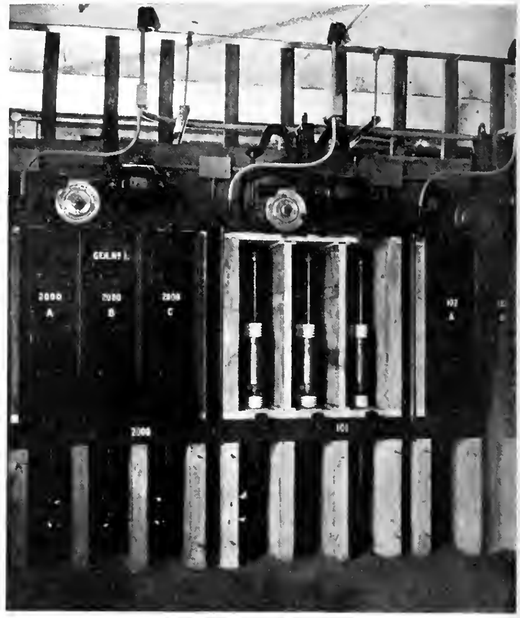

FIG. 4.—SWITCH COMPARTMENT, FIRST GALLERY.

In the first section of the building will be installed 32 boilers approximately 630 hp each. These are arranged in batteries of two, and are so set that all walls may be easily examined. The boilers are equipped with a complete double system of feed water supply, the first from the hot water feed water system, and the second by individual injectors for each boiler connected with tanks, placed above the boilers—the injectors being intended for emergency use only. Special care has been given to the installation of the feed water piping, fittings being avoided whenever possible, and bent brass pipe used.

Coal is supplied by means of chutes arranged close to the columns, the spout being bent in order that the coal can be dumped on the center of the floor should it be required.

The second boiler room is a duplicate of the first boiler room with the exception that the flues pass up and through the coal-bunker floor to reach openings in the stack, provided at this point.

The coal-bunker is divided into pockets, first to admit of the flues passing across the building; and second, to prevent fire from being communicated from one portion of the coal-bunker to an-

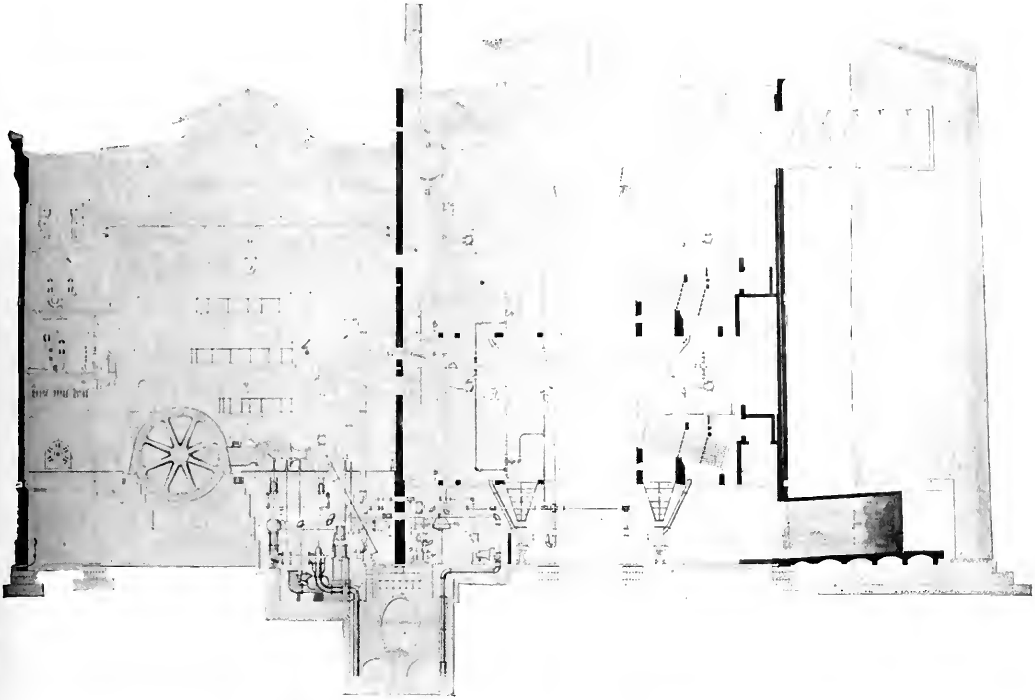

FIG. 5.—CROSS-SECTION VIEW OF STATION A, CHRISTIAN STREET, PHILADELPHIA.

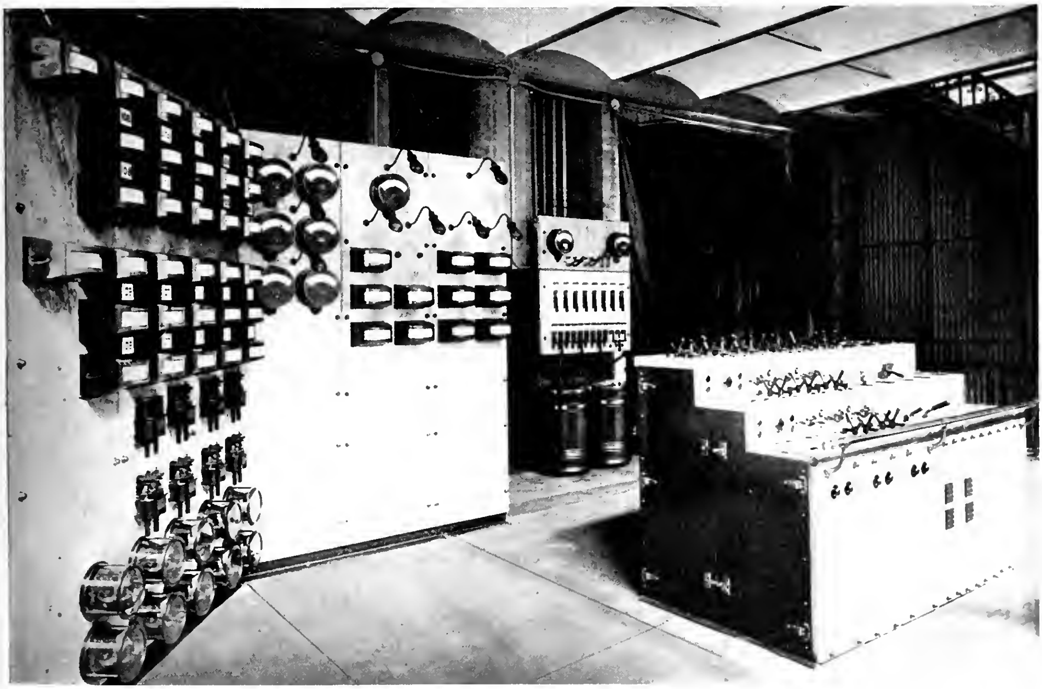

FIG. 6.—OPERATING TABLE AND FEEDER AND INSTRUMENT PANELS.

ELECTRIC LIGHTING IN THE CITY OF BENJAMIN FRANKLIN.

other, thus entirely obviating the danger from this cause. Should the coal ignite from any cause, the pocket could immediately be drained on either of the boiler-room floors.

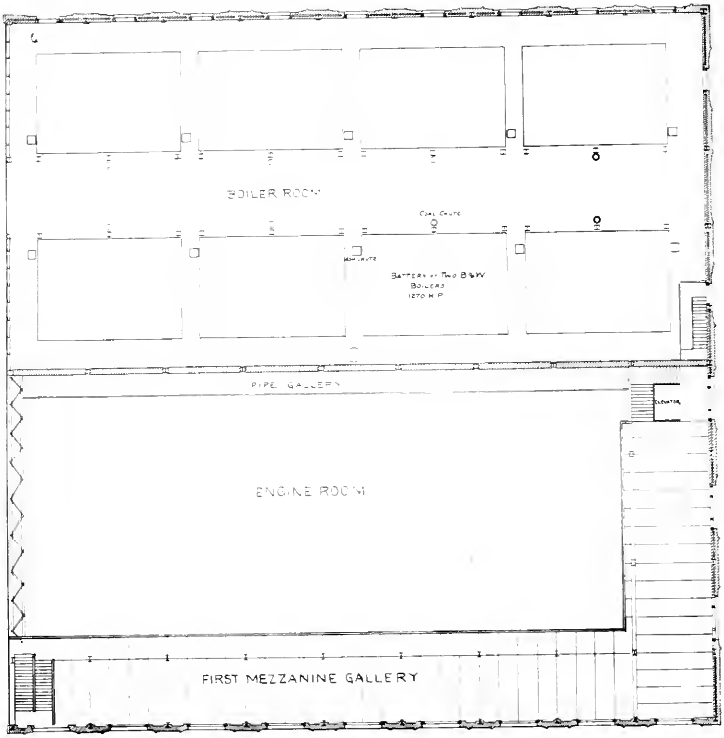

FIG. 7.—FIRST FLOOR PLAN OF POWER HOUSE.

tween the coal-bunkers and the roof is provided with a liberal number of copper louvres so as to admit of ventilation. Each space above the flue-crossing is provided with a "Star" ventilator. All stairways are metal, and strict attention has been given to making the building as nearly fire-proof as practicable. All the doors between the engine room building and the boiler room building are standard Underwriter fire-proof doors.

The engine room building, which fronts on Christian Street, is similar in external appearance to the boiler room building, both being built of red stretcher brick and the general design consisting of large panels arranged between the structural steel columns, this being an inexpensive but ornamental design. The panels in the boiler room building are partially bricked up and the engine room walls are almost entirely utilized for windows, making a very light engine room. The engine room is further provided with a lantern extending along the engine room proper. The lantern is laid with wired glass, the glass overhanging the removable ventilating sash, so that in the event of a heavy wind or rain storm it is not necessary to close the ventilating sash.

All of the metal work exposed to the weather is covered with sheet copper, including the cornices and rain spouts, it being the intention that the building is to be as permanent and lasting as possible. The engine building is lined with light-colored enameled brick to six feet above the engine floor, the other part being buff color.

The mezzanine floors are provided with heavy solid balustrades, which prevent material from dropping through, and would admit of these floors being enclosed should it be found desirable. The switchboard and all its appliances are arranged in the various mezzanine floors on the Christian Street

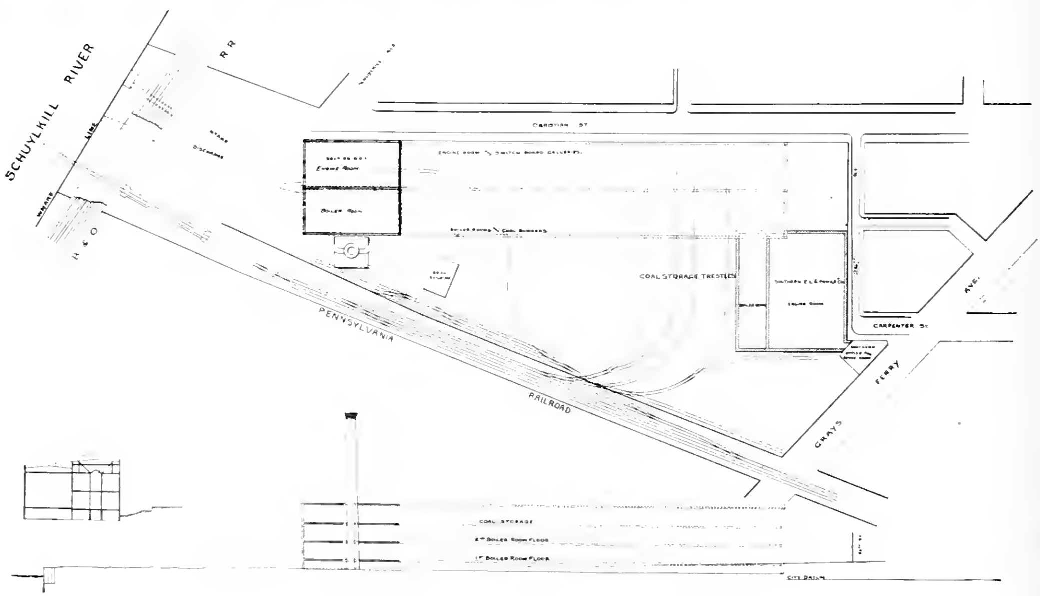

FIG. 8.—PROPERTY PLAN, PHILADELPHIA ELECTRIC COMPANY.

Coal is delivered to the coal-bunker by means of two bucket elevators at the end of the building and distributed by two horizontal conveyors running above the coal-bunkers. The space be-side. The floors on the end facing the river are used for offices, storerooms and executive purposes.

Referring to the floor plan, it will be noted that in the boiler-room the boilers are first arranged in batteries of two, and the batteries facing each other are connected to steam pipes which in turn feed the main header which is located on a division wall on the engine room side. This main header is arranged zigzag fashion; one section joins two batteries on one floor, rises and joins two batteries on the floor above. In this way the expansion and contraction of the main header is taken care of, and the line is always exposed to view. All joints are readily accessible, as permanent iron galleries are arranged parallel with the steam pipe.

FIG. 9.—DIRECT-CURRENT AND EXCITER SWITCHBOARD.

The condensing apparatus is arranged on the boiler room side of the engine room and the auxiliaries are placed in the basement, this position making them adjacent to the auxiliaries for the boiler room, but separated from them by the division wall. They are, however, readily accessible on account of the doors placed for this purpose.

The 2,000-kw unit is driven by a cross double-tandem compound Wetherill Corliss Engine. The 5,000-kw unit is driven by a combined vertical and horizontal double-compound Reynolds-Corliss engine built by the Allis-Chalmers Company. The condenser for the 2,000-hp unit is of the jet type, and for the 5,000-kw unit is a Weiss injector condenser.

Special effort has been made to simplify the installation of the cables and electrical equipment and to keep the steam and electrical equipment entirely separate from each other, so that the steam pipes shall not cross the electrical conductors or vice versa. Cables immediately upon leaving the generators enter a terra cotta conduit and are conducted through continuous terra cotta conduits to the terminus. There are two sets of cables which should receive consideration, first the cables running from and to the generators, and second, the feeder cables leaving the station.

The feeders are distributed along the entire length of the Christain Street side. These cables are arranged in groups of six, and enter separate manholes distributed along the street front of the building, so that there is no bunching of cables in any manhole. The first conduit laid consisted of twenty-four 3½-in. terra cotta conduits. Drawings were prepared showing the layout of each cable from the station to the sub-station. The manholes were designed specially so as to admit of easy access to the cables, and at the same time protect the cables in the event of either gas explosions in manholes or short-circuits of adjacent cables. The manholes are of octagonal shape, and are provided with soapstone shelves which fulfill the function of supporting the cable and acting as a barrier, so that a short-circuit in one cable cannot be communicated to its neighbor. The conduit is spread at the point of entering the manhole so as to bring the end of the duct in line with the shelf upon which the cable will rest. This prevents any sharp bends and admits of cables being installed in a safe and convenient manner.

The station terminal of the cable is on the ground floor and consists of a series of concrete cells, the cable being provided with a pot-head at this point and spreading from a three-conductor cable to single-conductor cable. In these compartments are placed single-pole disconnectors. These disconnectors are similar to knife-switches without handles, and arranged to be opened with a detachable rod. The object of these disconnectors is to enable the cable department to know that current is not thrown on the cable when out of service and under repairs. Immediately above these compartments are placed static discharge devices which consist of an arrangement of spark gaps and graphite resistances similar to lightning arresters. They are protected by means of a small enclosed fuse and are enclosed in cases to keep out the dust. From these compartments the cable enters a terra cotta conduit which passes through the engine-room wall, is then exposed to the first mezzanine floor, and enters the concrete compartments leading to the oil switches and to the transformers, both series and potential.

The arrangement of the switchboard is in three tiers. First, automatic switches, or what might be called the operating switches; second, the reserve switches, which are placed above on the bus-bars, which occupy the highest tier. The intermediate tier consists of two oil switches, one of which is connected to either bus-bar, so that at all times two oil switches are in series.

Connections to the bus-bars are made with disconnectors similar to those used in cable compartments on the ground floor, so that it is unnecessary to remove any bolts or fastenings to disconnect any line from the bus-bars or from the outgoing feeders. This arrangement also enables the generators to be connected to any point of the bus-bars, minimizing the amount of copper used for that purpose. All of the switches are of the remote control type, an operating table being placed on the intermediate gallery.

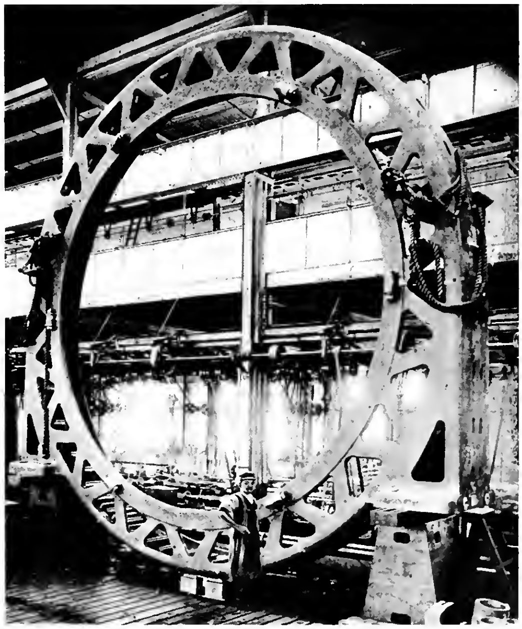

FIG. 10.—ARMATURE FRAME OF 6,000-VOLT GENERATOR.

The oil switches and high-tension bus bars are all arranged in concrete and soapstone compartments. As each switch section is a unit, and practically all of the units are similar, the concrete type of construction permitted the same moulds being used for building up all of the compartments. The switches were set sufficiently high from the floor to enable easy access to the base of the switch and prevent sharp bends of the cable. On the back of the switch compartments on the first gallery are arranged the transformer compartments, which are of similar concrete construction and separated by means of a concrete wall. Provision has been made to ventilate all of these compartments so that in the event of an arc being formed, the flame will pass out through the vents, striking the division wall, and cannot be communicated to any of the other compartments.

The transformer compartment contains two series transformers and one potential transformer. The cases and frames of all of the transformers are grounded with heavy copper strips laid in the concrete. This copper strip is also connected to angle irons set in the concrete to which the various transformers are attached. One of the series transformers is used to operate the automatic switches by means of time, limit relays, and the other furnishes current for various indicating and recording instruments.

The potential transformer is of 600 watts capacity and is large enough to supply all pilot lamps and all indicating and recording instruments required.

All of the secondary wires from these transformers and the low-tension direct circuit supplying the motors operating the oil switches are installed in iron armored conduit, so that there are no exposed wires either high-tension or low-tension in the switchboard construction. All of the concrete compartments are provided with fireproof doors; and as the operating switchboard is entirely low-tension, being either the secondaries from the transformers or direct current supplying the operating motors, there is no danger from any cause to attendants, as in the event of failure and breaking down of the transformer the high-tension current is grounded through the strips provided for that purpose.

This table is arranged in steps similar to the keyboard of an organ so as more clearly to define the various groups of switches. Each feeder is controlled at this point by means of three switches, one automatic switch and two selector switches. These switches are provided with pilot lamps which indicate the position of the switch. The instruments are located on an instrument board immediately in front of the controlling table and upon this are mounted for each feeder a pilot lamp which indicates the number of the feeder, an ammeter and a recording wattmeter on each phase of the feeder. The generator control consists of the three switches. In this case all of the switches are hand-operated, no automatic switches being used on the generators. The main switch is controlled by a different type of handle to distinguish it from the selector switches. These are placed at the top of the table so as to be out of the way. On the next step is a switch to open the field circuit of the generator, and the switch for varying the speed of the engine for synchronizing. The lower step contains the field rheostat and synchronizing plugs. On the front of the table are the switches controlling the exciter sets. The indicating instruments on each generator are pilot lamps, voltmeters, ammeters and indicating wattmeters.

The instrument board is arranged with generator instruments and exciter instruments parallel to the control table, and the feeders are arranged on an offset at an angle of 45°, which concentrates the instruments and assists the vision of the operator as well as enabling him to differentiate between the different classes of instruments.

Cincinnati A. I. E. E. Local Meeting.

The February local meeting of the Cincinnati branch of the American Institute of Electrical Engineers was prefaced by a dinner at the Grand Hotel, at which 53 persons were seated. The meeting was held in the hotel auditorium, at which Mr. W. A. Blanck, of the Arnold Electric Power Station Company, read a paper on "Single-Phase Railroads." After outlining the various systems which have been tried—the synchronous motor driving a generator mounted on the train, the induction motor as a subdivision of this, the Arnold system of induction motor and air compressor combined, the alternating-current series motor, the repulsion induction motor as developed by Steinmetz and Schuler, and lastly the repulsio nseries motor of the Union Electric Company, of Berlin—Mr. Blanck took up the subject of controllers, car wiring, trolley bow and line construction. He then took a typical sixty-mile road equipped both by the present system of alternating-current generator with rotary converter, sub-stations and the system using transformer sub-stations and 3,000 volts on the trolley line. Comparing item for item he showed that the direct-current system giving the same service as a single-phase system costs 32 per cent. more than the alternating system. The paper was thoroughly discussed. At the next meeting it is hoped to have a paper on steam turbines.

The Development of Alternating-Current Work in America.

By Charles Appleton Terry.

Your request for reminiscences concerning the development of the commercial alternating-current system carries one's thoughts back to the early eighties when, though the direct-current system was in fairly extensive use, the alternating current had yet to receive the serious consideration of our engineers. Looking back over this period, the names of a few individuals stand out with peculiar prominence.

It is needless to say that the personality of Mr. Westinghouse is most conspicuously interwoven with the entire development of this system. When the work of Gaulard & Gibbs was first brought to his attention, he engaged the services of one of the most prominent of the electrical engineers of that time, Franklin L. Pope, a man whose quiet, forceful work aided greatly in the successful introduction of the alternating system to a skeptical public. Mr. Pope possessed an extraordinarily resourceful mind and a retentive memory stored with useful facts and apt information. His rare sense of humor and genial kindness of manner were combined with a persistence of will and untiring studiousness which had rendered him a recognized authority upon all electrical subjects; and to-day his publications upon telegraphy and kindred subjects are valuable works of reference. His railway signalling inventions had brought him into close association with Mr. Westinghouse, and it thus came about that in February, 1886, as a direct result of experiments made with the Gaulard & Gibbs system at Pittsburg in 1885, Mr. Pope went to England commissioned by Mr. Westinghouse to secure the American rights to the Gaulard & Gibbs system. Throughout the formative period of the system, Mr. Pope was closely identified with the patent and scientific matters involved.

The rapid march from the experimental plant of 1885, to the commercial plant installed at Buffalo in November, 1886, was largely to the credit of the engineering ability of Shallenberger, Stanley and Belfield. Within a year thereafter sixty-five plants were sold, representing a total generating capacity of 125,000 incandescent lamps. Almost immediately a strong opposition to the alternating system was developed by the partisans of the direct-current system, an opposition which though gradually lessened did not cease until the commercial advent of the rotary transformer or converter which wedded the two systems.

In the earlier days the alternating system was at first seriously handicapped by the lack of a meter and a power motor. In April, 1888, Shallenberger, while experimenting with an arc lamp, noted a peculiar action of a small coiled spring which accidentally lodged on the brass flange of the magnet spool; the spring slowly turned about its longitudinal axis. From this accidental circumstance Shallenberger within a month developed his alternating-current meter, which for nearly ten years was the principal recording meter for this system, the only other commercial one being that devised by Prof. Elihu Thomson, who also made important inventions in the alternating-current field.

The requirement of a motor was met by Tesla's discoveries, the public announcement of which was nearly coincident with the indedependent discovery of Shallenberger and the publication of Ferrari's work along similar lines. Tesla's discoveries, however, included the polyphase system, which lent itself more perfectly to the distribution of large power units.

There still remained the requirement of a power motor adapted to railway service, and this is now being met by the assured single-phase motors of Lamme and Steinmetz.

It would seem that as a result of this perseverance of those interested in the alternating-current system, the perfection of the detail apparatus and the growing appreciation of its possibilities, the handicap now rests upon the shoulders of the direct-current system rather than upon that using the current which Shallenberger once described as "the electric current as God gave it to us."

The Transmission of Electric Energy Without Wires.

BY NIKOLA TESLA.

IT is impossible to resist your courteous request extended on an occasion of such moment in the life of your journal. Your letter has vivified the memory of our beginning friendship, of the first imperfect attempts and undeserved successes, of kindnesses and misunderstandings. It has brought painfully to my mind the greatness of early expectations, the quick flight of time, and, alas! the smallness of realizations. The following lines which, but for your initiative, might not have been given to the world for a long time yet, are an offering in the friendly spirit of old, and my best wishes for your future success accompany them.

Towards the close of 1898 a systematic research, carried on for a number of years with the object of perfecting a method of transmission of electrical energy through the natural medium, led me to recognize three important necessities: First, to develop a transmitter of great power; second, to perfect means for individualizing and isolating the energy transmitted; and, third, to ascertain the laws of propagation of currents through the earth and the atmosphere. Various reasons, not the least of which was the help proferred by my friend Leonard E. Curtis and the Colorado Springs Electric Company, determined me to select for my experimental investigations the large plateau, two thousand meters above sea level, in the vicinity of that delightful resort, which I reached late in May, 1899. I had not been there but a few days when I congratulated myself on the happy choice and I began the task, for which I had long trained myself, with a grateful sense and full of inspiring hope. The perfect purity of the air, the unequaled beauty of the sky, the imposing sight of a high mountain range, the quiet and restfulness of the place—all around contributed to make the conditions for scientific observation ideal. To this was added the exhilarating influence of a glorious climate and a singular sharpening of the senses. In those regions the organs undergo perceptible physical changes. The eyes assume an extraordinary limpidity, improving vision; the ears dry out and become more susceptible to sound. Objects can be clearly distinguished there at distances such that I prefer to have them told by someone else, and I have heard—this I can venture to vouch for—the claps of thunder seven and eight hundred kilometers away. I might have done better still, had it not been tedious to wait for the sounds to arrive, in definite intervals, as heralded precisely by an electrical indicating apparatus—nearly an hour before.

In the middle of June, while preparations for other work were going on, I arranged one of my receiving transformers with the view of determining in a novel manner, experimentally, the electric potential of the globe and studying its periodic and casual fluctuations. This formed part of a plan carefully mapped out in advance. A highly sensitive, self-restorative device, controlling a recording instrument, was included in the secondary circuit, while the primary was connected to the ground and an elevated terminal of adjustable capacity. The variations of potential gave rise to electric surgings in the primary; these generated secondary currents, which in turn affected the sensitive device and recorder in proportion to their intensity. The earth was found to be, literally, alive with electrical vibrations, and soon I was deeply absorbed in this interesting investigation. No better opportunities for such observations as I intended to make could be found anywhere. Colorado is a country famous for the natural displays of electric force. In that dry and rarefied atmosphere the sun's rays beat the objects with fierce intensity. I raised steam, to a dangerous pressure, in barrels filled with concentrated salt solution, and the tinfoil coatings of some of my elevated terminals shriveled up in the fiery blaze. An experimental high-tension transformer, carelessly exposed to the rays of the setting sun, had most of its insulating compound melted out and was rendered useless. Aided by the dryness and rarefaction of the air, the water evaporates as in a boiler, and static electricity is developed in abundance. Lightning' discharges are, accordingly, very frequent and sometimes of inconceivable violence. On one occasion approximately twelve thousand discharges occurred in two hours, and all in a radius of certainly less than fifty kilometers from the laboratory. Many of them resembled gigantic trees of fire with the trunks up or down. I never saw fire balls, but as a compensation for my disappointment I succeeded later in determining the mode of their formation and producing them artificially.

In the latter part of the same month I noticed several times that my instruments were affected stronger by discharges taking place at great distances than by those near by. This puzzled me very much. What was the cause? A number of observations proved that it could not be due to the differences in the intensity of the individual discharges, and I readily ascertained that the phenomenon was not the result of a varying relation between the periods of my receiving circuits and those of the terrestrial disturbances. One night, as I was walking home with an assistant, meditating over these experiences, I was suddenly staggered by a thought. Years ago, when I wrote a chapter of my lecture before the Franklin Institute and the National Electric Light Association, it had presented itself to me, but I had dismissed it as absurd and impossible. I banished it again. Nevertheless, my instinct was aroused and somehow I felt that I was nearing a great revelation.

It was on the third of July—the date I shall never forget—when I obtained the first decisive experimental evidence of a truth of overwhelming importance for the advancement of humanity. A dense mass of strongly charged clouds gathered in the west and towards the evening a violent storm broke loose which, after spending much of its fury in the mountains, was driven away with great velocity over the plains. Heavy and long persisting arcs formed almost in regular time intervals. My observations were now greatly facilitated and rendered more accurate by the experiences already gained. I was able to handle my instruments quickly and I was prepared. The recording apparatus being properly adjusted, its indications became fainter and fainter with the increasing distance of the storm, until they ceased altogether. I was watching in eager expectation. Surely enough, in a little while the indications again began, grew stronger and stronger and, after passing through a maximum, gradually decreased and ceased once more. Many times, in regularly recurring intervals, the same actions were repeated until the storm which, as evident from simple computations, was moving with nearly constant speed, had retreated to a distance of about three hundred kilometers. Nor did these strange actions stop then, but continued to manifest themselves with undiminished force. Subsequently, similar observations were also made by my assistant, Mr. Fritz Lowenstein, and shortly afterward several admirable opportunities presented themselves which brought out, still more forcibly, and unmistakably, the true nature of the wonderful phenomenon. No doubt whatever remained: I was observing stationary waves.

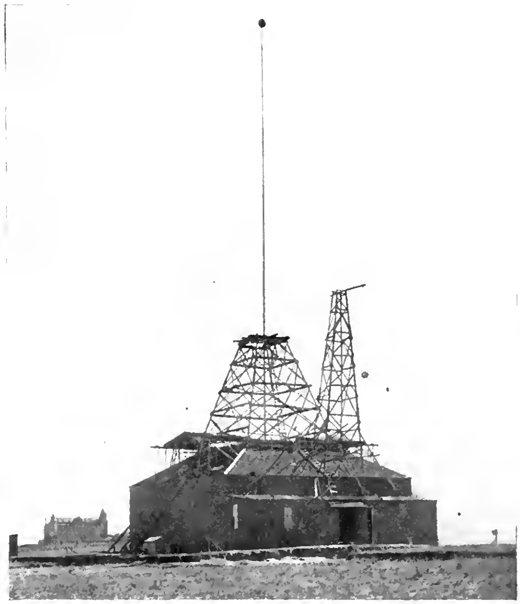

FIG. I.—TESLA EXPERIMENTAL LABORATORY, COLORADO, ERECTED SUMMER OF 1899.

(Discovery by Mr. Tesla of the Stationary Waves in the Earth was Here Made.)

As the source of disturbances moved away the receiving circuit came successively upon their nodes and loops. Impossible as it seemed, this planet, despite its vast extent, behaved like a conductor of limited dimensions. The tremendous significance of this fact in the transmission of energy by my system had already become quite clear to me. Not only was it practicable to send telegraphic messages to any distance without wires, as I recognized long ago, but also to impress upon the entire globe the faint modulations of the human voice, far more still, to transmit power, in unlimited amounts, to any terrestrial distance and almost without any loss.

With these stupendous possibilities in sight, with the experimental evidence before me that their realization was henceforth merely a question of expert knowledge, patience and skill, I attacked vigorously the development of my magnifying transmitter, now, however, not so much with the original intention of producing one of great power, as with the object of learning how to construct the best one. This is, essentially, a circuit of very high self-induction and small resistance which in its arrangement, mode of excitation and action, may be said to be the diametrically opposite of a transmitting circuit typical of telegraphy by Hertzian or electromagnetic radiations. It is difficult to form an adequate idea of the marvelous

FIG. 2.—TESLA CENTRAL POWER PLANT AND TRANSMITTING TOWER FOR WORLD TELEGRAPHY, WARDENCLYFFE, LONG ISLAND, N. Y.

(Tower is a pyramid having eight sides; smallest dimensions across base, 29 meters; height, 47 meters; total height from ground to top, 57 meters; cupola on top, 20 meters diameter.)

power of this unique appliance, by the aid of which the globe will be transformed. The electromagnetic radiations being reduced to an insignificant quantity, and proper conditions of resonance maintained, the circuit acts like an immense pendulum, storing indefinitely the energy of the primary exciting impulses and impressing upon the earth and its conducting atmosphere uniform harmonic oscillations of intensities which, as actual tests have shown, may be pushed so far as to surpass those attained in the natural displays of static electricity.

Simultaneously with these endeavors, the means of individualization and isolation were gradually improved. Great importance was attached to this, for it was found that simple tuning was not sufficient to meet the vigorous practical requirements. The fundamental idea of employing a number of distinctive elements, co-operatively associated, for the purpose of isolating energy transmitted, I trace directly to my perusal of Spencer's clear and suggestive exposition of the human nerve mechanism. The influence of this principle on the transmission of intelligence, and electrical energy in general, cannot as yet be estimated, for the art is still in the embryonic stage; but many thousands of simultaneous telegraphic and telephonic messages, through one single conducting channel, natural or artificial, and without serious mutual interference, are certainly practicable, while millions are possible. On the other hand, any desired degree of individualization may be secured by the use of a great number of co-operative elements and arbitrary variation of their distinctive features and order of succession. For obvious reasons, the principle will also be valuable in the extension of the distance of transmission.

Progress though of necessity slow was steady and sure, for the objects aimed at were in a direction of my constant study and exercise. It is, therefore, not astonishing that before the end of 1899 I completed the task undertaken and reached the results which I have announced in my article in the *Century Magazine* of June, 1900, every word of which was carefully weighed.

Much has already been done towards making my system commercially available, in the transmission of energy in small amounts for specific purposes, as well as on an industrial scale. The results attained by me have made my scheme of intelligence transmission, for which the name of "World Telegraphy" has been suggested, easily realizable. It constitutes, I believe, in its principle of operation, means employed and capacities of application, a radical and fruitful departure from what has been done heretofore. I have no doubt that it will prove very efficient in enlightening the masses, particularly in still uncivilized countries and less accessible regions, and that it will add materially to general safety, comfort and convenience, and maintenance of peaceful relations. It involves the employment of a number of plants, all of which are capable of transmitting individualized signals to the uttermost confines of the earth. Each of them will be preferably located near some important center of civilization and the news it receives through any channel will be flashed to all points of the globe. A cheap and simple device, which might be carried in one's pocket may then be set up somewhere on sea or land, and it will record the world's news or such special messages as may be intended for it. Thus the entire earth will be converted into a huge brain, as it were, capable of response in every one of its parts. Since a single plant of but one hundred horse-power can operate hundreds of millions of instruments, the system will have a virtually infinite working capacity, and it must needs immensely facilitate and cheapen the transmission of intelligence.

The first of these central plants would have been already completed had it not been for unforeseen delays which, fortunately, have nothing to do with its purely technical features. But this loss of time, while vexatious, may, after all, prove to be a blessing in disguise. The best design of which I knew has been adopted, and the transmitter will emit a wave complex of a total maximum activity of ten million horse-power, one per cent. of which is amply sufficient to "girdle the globe." This enormous rate of energy delivery, approximately twice that of the combined falls of Niagara, is obtainable only by the use of certain artifices, which I shall make known in due course.

For a large part of the work which I have done so far I am indebted to the noble generosity of Mr. J. Pierpont Morgan, which was all the more welcome and stimulating, as it was extended at a time when those, who have since promised most, were the greatest of doubters. I have also to thank my friend, Stanford White, for much unselfish and valuable assistance. This work is now far advanced, and though the results may be tardy, they are sure to come.

Meanwhile, the transmission of energy on an industrial scale is not being neglected. The Canadian Niagara Power Company have offered me a splendid inducement, and next to achieving success for the sake of the art, it will give me the greatest satisfaction to make their concession financially profitable to them. In this first power plant, which I have been designing since a long time, I propose to distribute ten thousand horse-power under a tension of one hundred million volts, which I am now able to produce and handle with safety.

This energy will be collected all over the globe preferably in small amounts, ranging from a fraction of one to a few horse-power. One of its chief uses will be the illumination of isolated homes. It takes very little power to light a dwelling with vacuum tubes operated by high-frequency currents and in each instance a terminal a little above the roof will be sufficient. Another valuable application will be the driving of clocks and other such apparatus. These clocks will be exceedingly simple, will require absolutely no attention and will indicate rigorously correct time. The idea of impressing upon the earth American time is fascinating and very likely to become popular. There are innumerable devices of all kinds which are either now employed or can be supplied, and by operating them in this manner I may be able to offer a great convenience to the whole world with a plant of no more than ten thousand horse-power. The introduction of this system will give opportunities for invention and manufacture such as have never presented themselves before.

Knowing the far-reaching importance of this first attempt and its effect upon future development, I shall proceed slowly and carefully. Experience has taught me not to assign a term to enterprises the consummation of which is not wholly dependent on my own abilities and exertions. But I am hopeful that these great realizations are not far off, and I know that when this first work is completed they will follow with mathematical certitude.

When the great truth accidentally revealed and experimentally confirmed is fully recognized, that this planet, with all its appalling immensity, is to electric currents virtually no more than a small metal ball and that by virtue of this fact many possibilities, each baffling imagination and of incalculable consequence, are rendered absolutely sure of accomplishment; when the first plant is inaugurated and it is shown that a telegraphic message, almost as secret and non-interferable as a thought, can be transmitted to any terrestrial distance, the sound of the human voice, with all its intonations and inflections faithfully and instantly reproduced at any other point of the globe, the energy of a waterfall made available for supplying light, heat or motive power, anywhere—on sea, or land, or high in the air—humanity will be like an antheap stirred up with a stick: See the excitement coming!

The Beginnings of the Incandescent Lamp.

By THOS. A. EDISON.

IN response to the kind suggestion of the ELECTRICAL WORLD AND ENGINEER that the celebration of its completion of thirty years of existence affords a fitting opportunity to recall the beginnings of the incandescent lamp, I am glad to put on record a brief personal narrative of the details connected with what was to me a very interesting period of electrical development. The occasion is not only a reminder of the rapid flight of time, but of the fact that since 1874—the year of the quadruplex, by the way—all the great modern departments of electrical industry have sprung into vigorous being. We telegraphers have a right to claim this journal also as part of our contribution to the art.

My experiments on carbon began in 1876, when I had the idea of making carbon wire, etc., for various electrical and chemical purposes. Even at that early time Messrs. Charles Batchelor and E. H. Johnson were with me, and we saw quite a business ahead in carbon novelties. I had familiarized myself with the properties of carbon, particularly that made from paper and Bristol board, and this led on very naturally to my work on the carbon telephone or microphonic transmitter, early in 1877. In the fall of that year I was pretty well through with studies and inventions in that line, but had several other ideas that I wanted to work up. One of these was the subdivision of the electric light, and I began experimenting with that purpose. My records and the voluminous testimony in litigation, now happily long past, show that in the fall of 1877, about September, strips of carbonized paper were tried as an incandescent conductor suitable for use in lamps, and the work was followed up until January of 1878, when the general excitement over my invention and exhibition of the phonograph out at old Menlo Park frustrated serious or continuous work for a time, in any other direction. In fact, my health gave way under the strain, and in July I broke away for a Western trip as far as California.

Of course my mind was turning the subject over, and when I got back in August we immediately went at it again. Around October and November Batchelor made a great number of paper carbons, at least 50, from tissue and other kinds of paper, coated over their surface with a mixture of lampblack and tar, rolled up into the fine long form of a knitting needle, and then carbonized. These we put into circuit and brought up to incandescence in vacuo; although they would last but an hour or two. We tried a great many experiments with paper carbons, wood carbons and some made from carbonized broom corn. What we desired at that date, and had settled our minds upon as the only possible solution of the subdivision of the electric light, was that the lamps must have a high resistance and small radiating surface. About December, 1878, I engaged as my mathematician Mr. Francis R. Upton, who had lately studied under Helmholtz, in Germany, and he helped me greatly in calculations of the multiple arc problem. Our figures proved that the lamp must have at least 100 ohms resistance to compete successfully with gas; for if the lamps were of low resistance the cost of the copper main conductors would be so great as to render the system uneconomical and commercially impracticable. In this direction we tried platinum also; and when working on incandescent platinum we had procured a Sprengel mercury pump and had ascertained that we could thus get exceedingly high

FIG. 1.—FIRST PHOTOGRAPH TAKEN BY INCANDESCENT LIGHT.

(Reproduction of Photograph taken by Mr. Edison at his Menlo Park Laboratory at midnight about Dec. 20, 1879, by the light of three of his first electric lamps. The portrait is that of Mr. Charles Batchelor.)

vacua. It occurred to me that perhaps a "filament" of carbon could be made to stand in the sealed glass vessels or bulbs, which we were using, exhausted to a high vacuum. Separate lamps were made in this way independent of the air pump, and in October, 1879, we made lamps of paper carbon, and with carbons of common sewing thread, placed in a receiver or bulb made entirely of glass, with the leading-in wires sealed in by fusion. The whole thing was exhausted by the Sprengel pump to nearly one-millionth of an atmosphere. These filaments of carbon, although naturally quite fragile owing to their length and small mass, had a smaller radiating surface and

FIG. 2.—VIEW OF EDISON LABORATORY, MENLO PARK, N. J.

(Showing buildings and outdoor circuits lighted by incandescent lamps, December, 1879.)

higher resistance than we had dared hope. We had virtually reached the position and condition where the carbons were stable. In other words, the incandescent lamp as we still know it to-day, in essentially all its particulars unchanged, had been born.

We began immediately to make vacuum pumps and to produce these paper filament lamps on them. During that November we made perhaps as many as 100 of such lamps, and the same month saw us plunged deep in experiments and inventions on dynamos, regulators, meters, circuits, etc., all just as necessary to the success of the art as the little lamp itself. Some of those paper filament lamps had a remarkably long life. Each yielded from 12 to 16 cp and they were burned on chandeliers until they gave out. The average life was about 300 hours. One of them lasted 940 hours and another 1,350 hours, so that commercial success and a new industry were already well in sight.

But I was not quite satisfied as to paper, or even with the more regular and homogeneous wood fibre filaments, and thus came to take up bamboo. We happened to have a palm leaf fan on one of the tables. I was then investigating everything with a microscope, so I picked it up and found that it had a rim on the outside, of bamboo, a very long strip cut from the outer edge. We soon had that cut up into blanks and carbonized. On putting these filaments into the lamps we were gratified to see that the lamps were several times better than any we had succeeded in making before. I soon ascertained why and started a man off for Japan on a bamboo hunt. Before I got through I had tested no fewer than 6,000 vegetable growths, and had ransacked the world for the most suitable bamboo. The use of bamboo was maintained for many years until other processes dealing with such material as cellulose had been perfected. We tried even at the earliest moment of success a number of experiments and things afterwards taken up again or followed through, as for example, burning the paper filaments in a vacuum charged with inert gas; and a little later, in 1880, we also "flashed" the filaments with gasoline vapor.

The furore that followed the announcements from Menlo Park as to the successful subdivision of the electric light in a commercial incandescent lamp will be well remembered by many of the readers of this. The feasibility of such a thing had been denied by some of the greatest minds in electricity, but here it was; and along lines that have endured to this day. The best story at the time was given to the world by the New York *Herald* in December, 1879, and on Christmas Day I had already lighted up my laboratory, my offices, two or three houses about one-fifth of a mile from the dynamo plant and some twenty street lights. On the last day of the year some 3,000 people flocked out to Menlo Park to see it for themselves —and the rest everybody knows.

It is interesting to note that in addition to those mentioned above I had around me other men who ever since have remained active in the field, such as Messrs. Francis Jehl, W. J. Hammer, Martin Force, Ludwig Boehm, not forgetting that good friend and co-worker, the late John Kruesi. They found plenty to do in the various developments of the art, and as I now look back I sometimes wonder how we did so much in so short a time. Early in the spring of 1880 I lighted up for Mr. Villard the Oregon Steam Navigation Company's steamer *Columbia,* and it was not long before the Edison plants began to multiply. Meantime lamp making took on large proportions in two factories of mine, one at old Menlo Park and the other at Newark, and much of my energy was being devoted to cheapening the price of the lamp as well as increasing its life and its candle-power per watt. I am told that upon a moderate computation the production of incandescent lamps in this country since my first success has reached a total of 250,000,000 lamps, or not less than 10,000,000 a year for each of the 25 years. Essentially, the lamp has remained structurally the same ever since 1879, in the elements then demonstrated to be essentially vital and necessary to commercial success.

The Success of Loaded Lines in Telephony.

Upon the announcement of Dr. Pupin's invention, successfully applying self-induction to the improvement of telephone lines, there was much sensational talk in the daily newspapers and elsewhere concerning the use of the invention in telephoning across the Atlantic. The possibilities of such a brilliant project were so attractive that little attention has been given by the public to very important but less sensational applications of Dr. Pupin's work. Accounts of experiments with Pupin coils in Germany and of the successful patent litigation there in their behalf, have been given in these columns from time to time. In this article, we give an account of some of the important steps which have been taken in this country looking to the introduction of the new form of telephone conductor.

Following quickly upon the purchase of the Pupin patent by the Bell interests, overhead lines were loaded from New York to Chicago and to other points in the West. Although a great deal of valuable experimental data has been obtained, the extension of the loading of overhead lines has not been continued. Unforeseen difficulties in the nature of cross-talk and leakage effects were encountered, and while they are not sufficient to prevent ultimately the extension of the system to overhead lines, they have called attention to a number of features in line construction which must be attended to before complete success in overhead loading is attained. A vast amount of work in overcoming these temporary difficulties has already been done, and although many points still require investigation, it is safe to say that this phase of the problem presents no difficulties which are insuperable and which cannot be expected to yield to patient and intelligent research.

In the loading of underground cables, a great deal of important and successful work has been accomplished, particularly in the neighborhood of New York City. From Cortlandt Street to Newark, N. J., a distance of about ten miles, there are working successfully 50 pairs in No. 19 B. & S. gauge cable, equipped with Pupin coils. Each of these circuits when loaded gives a talking equal to that which would be obtained through six miles of the No. 19 gauge cable unloaded. These 50 pairs have been in satisfactory service since August, 1902. From Cortlandt Street to Elizabeth, N. J., a distance of seventeen miles,. 50 pairs of No. 19 gauge conductors are also equipped with Pupin coils, and are giving satisfaction. The talk obtained over these seventeen miles of loaded cable is equal to that which would be obtained through about seven miles of the same kind of cable unloaded. From the central office in Brooklyn to Far Rockaway, Long Island, there is a cable of No. 19 gauge, partly underground and partly overhead. This cable is about eighteen miles long, and talks as well when equipped with Pupin coils as would eight miles of standard cable of No. 19 gauge operated without coils. From the Brooklyn central office to Jamaica, L. I., there is a standard cable of No. 19 gauge, twelve miles long, provided with Pupin coils. This cable talks as well when equipped with the coils as would six miles of the same kind of cable without the coils. From Cortlandt Street to Fordham, in the Borough of the Bronx, a distance of fourteen miles, there are fifty pairs of conductors of No. 16 B. & S. gauge equipped with Pupin coils. The talk through these fourteen miles of No. 16 gauge cable equipped with coils is as good as that which is obtainable through four and a half miles of No. 19 gauge standard cable without coils. From Cortlandt Street to Kingsbridge, in the Borough of the Bronx, a distance of fifteen miles, there are 50 pairs of No. 13 B. & S. gauge conductors in an underground cable equipped with Pupin coils. The talk through these fifteen miles of cable thus equipped with coils is equal to that which would be obtained through three miles of standard No. 19 gauge cable without coils. In all of these cases the conductors are being used satisfactorily for commercial business, and the results obtained are a splendid practical demonstration of the value of Dr. Pupin's theoretical work.

Although ocean telephony is not yet an accomplished fact, the application of loading to suburban trunk lines in the neighborhood of large cities has already proved to be of very great importance. All of the electrical principles involved in the problem of ocean telephony apply to that of underground land lines, and the fact that in those lines such successful results have been obtained has led some of our prominent engineers to express themselves most hopefully with reference to the ocean telephone cable.

Prior to the work of Dr. Pupin, there was no generally recognized method of overcoming the electrical difficulties presented by the problems of ocean telephony. Prof. Pupin has shown how to overcome these electrical difficulties. As the problem now stands, it is mainly a mechanical one, and consists in incorporating into an ocean cable at suitable intervals coils of iron and copper having the proper inductance. Looking at the problem broadly, it seems safe to say that greater mechanical difficulties than this have been overcome and that there is good reason to hope that during the life of the Pupin patent, we may witness the operation of a high speed ocean cable which would permit not only of the transmission of speech, but what would probably be more important, the successful use of high speed telegraphy across the Atlantic.

The effect of the Pupin invention upon long distance land lines is one which has been the subject of much debate. While there is no doubt that the art of loading has already greatly extended the effective range of underground telephone cables, it is a great mistake to assume that with the Pupin invention, the universal placing underground of telephone trunk lines is practicable. At the present time and for many years to come, the most important function of the invention will be to provide suitable underground circuits for the suburban trunk lines in the neighborhood of our great cities and to permit of "long distance" wires being placed underground for short distances within the great cities.

Notwithstanding the Pupin invention, the most practicable way of operating such long distance lines as that from New York to Chicago is to carry them overhead, except for short sections of loaded cable at each end. If it were attempted to place such lines underground throughout their entire length or even in the various intermediate towns and villages which they travers, the economies of long distance telephony would disappear and the public would be deprived of a most valuable adjunct to its commercial enterprise.

To the use of subscribers' lines extending to the central office the Pupin invention has no practical application. These lines are usually but a mile or two in length, and do not permit of being economically loaded.

The Development of Industrial Electrochemistry.

By Dr. E. F. Roeber.

While of all branches of electrical engineering electrochemistry has been the last one to achieve commercial successes on a large scale and may justly be considered to be still in the first phase of its industrial development, yet its fundamental principles were long exactly known (electrolytic action-Faraday's law, electrothermic action-Joulean heat). Moreover, at the beginning of the nineteenth century the very first experimental applications of the newly discovered electric current were of an electrochemical nature. Shortly after the primary battery had been invented by Volta, Nicholson and Carlisle succeeded in decomposing water by electrolysis, and in 1807 Sir Humphry Davy delivered his famous lecture on some chemical agencies of electricity. Yet (to quote from the recent Bradley patent decision) "Davy's experiments were permitted to lie dormant during seventy-six years of intense activity," and in general the progress in the development of industrial electrochemistry and electrometallurgy was extremely slow for a long period. In fact, thirty years ago, when the first issue of this journal appeared, there did not exist any electrochemical industries, with the single exceptions of electroplating and primary battery manufacture.

It is now not difficult to see what held the development of industrial electrochemistry back. In nearly all electrochemical and electrometallurgical processes the cost of the electric power is a large fraction of the total cost of operation, often 25 per cent. or more, and even up to 90 per cent. Cheap electric power is, therefore, the fundamental requirement for the economical working of an electrochemical process, in exactly the same way as it is for electric lighting, traction and power purposes in general. Before the advent of the dynamo, the primary battery was the only available source of the electric current, if we except a limited use of the thermo-pile, and its limitations are obvious. The operation of a primary cell meant and still means essentially oxidation of zinc. When zinc changes from the metallic state into bivalent ions, 1.22 grams are oxidized, according to Faraday's law, for every ampere-hour; we know that, with all possible combinations of zinc with other materials in a primary battery, we never get much more than 2 volts, and if we assume the useful e.m.f. to be 1 volt (which is very fair for such an estimate), then every kilowatt-hour produced means the oxidation of 1.22 kg (or 2¾ pounds) of zinc. This is the theoretical value which really represents a minimum of actual consumption; moreover, it does not include the cost of the other materials in the cell, nor the cost of construction and attendance; but it is sufficient to indicate the inherent limitations of the zinc primary battery.

So long as primary cells were the only commercial sources of electric current, the applications of electrical engineering were thus necessarily restricted to those cases in which a very small amount of power only is required. That is especially the case in telegraphy, and, in the field of electrochemistry in those cases of electroplating in which a soluble anode is used of the same metal which is to be deposited upon the cathode. Here the voltage required at the terminals of the plating bath is consumed in overcoming the internal resistance only, which may be made small, and, therefore, the power may also be insignificant.

It is quite natural that after the dynamo had made its commercial appearance, electric lighting and the mechanical applications of electricity, such as traction and power transmission and distribution, first attracted the inventive talents of electrical engineers. Nevertheless, as we were reminded by the recent Institute dinner to Mr. Edison, the incandescent lamp is now only 25 years old. It is, therefore, not surprising that our electrochemical industries are still young, since their development depended rather on chemists and metallurgists, who were attracted by the possibilities of the application of the electric current which had proven to be such a manageable and thoroughly reliable agent in other fields of engineering.

The following sketch naturally does not aim at completeness, and no attempt will be made to give details of processes. The object is rather to bring out some general principles which have manifested themselves all along during the development of the electrochemical industries—Leitmotives, to borrow a word from Wagner's operas. At the same time, we will try to arrive at a convenient classification of the whole subject. One general subdivision of all electrochemical processes and phenomena into two large classes offers itself. In the first class electrical energy is consumed to produce chemical effects, while in the second class chemical energy is changed into electrical energy. Thus, the second class comprises the whole field of primary cells and storage batteries, while in the first class we have all those more or less novel processes which are now mostly thought of when one speaks simply of electrochemical and electrometallurgical industries.

Chemical effects may be produced by means of electrical energy in various ways. We can change the electrical energy into heat, which is then consumed in producing the desired chemical effect; or we can change electrical energy into chemical energy directly by electrolysis; or we may use a combination of both methods; finally, a fourth method of producing chemical effects is by passing an electric discharge through gases. Before giving a cursory review of applications of these various principles, a general remark should be made on the nature of chemicals produced by such methods.

Many of these processes consume a considerable amount of electrical energy. In the discussion of furnace processes from the ordinary chemical point of view, we may, of course, say that the energy is expended to produce a certain temperature which is required to start the process. This, however, does not tell the whole story. We expend a certain amount of electrical energy which is lost while the process is going on. What becomes of it? If the process is conducted under fairly economical conditions most of the electrical energy is changed into chemical energy and is stored up in this form in the chemicals produced.

In other words, if an electrochemical process requires the expense of an appreciable amount of electrical energy, then the products of the process possess a higher content of chemical energy than the starting materials. This explains why electrochemical methods give us substances of strong chemical affinity. Moreover, these substances represent in a sense a storage of energy, which at the same time enables one to ship readily the stored energy to a point where it may be wanted. Two examples may explain this.

Aluminum does not occur free in nature and its separation from its compounds requires a considerable amount of energy. If we electrolyze aluminum oxide dissolved in a bath of fluorides, we get aluminum and oxygen; the formation heat of Al_2O_3 is 392,600 calories; hence, according to Thomson's rule (which is fully good enough for this purpose) we must apply at least 2.8 volts at the terminals of the cell. This voltage, multiplied by the coulombs passed through the cell, represents the electrical energy which is changed into chemical energy. That is what Hall does in producing aluminum in his cell. Now, we may ship the aluminum somewhere and may then allow it to combine again with oxygen to form back Al_2O_3. Then we get back our energy in the form of most intense heat. This is what Goldschmidt does in his thermit process. (Of course, he loses the energy which is required to reduce the iron oxide in the thermit; but this is small, compared with the formation heat of Al_2O_3.)

In the Union Carbide Works in Niagara the energy of the Falls, after conversion into electrical energy, is stored in form of chemical energy in calcium carbide. As long as we keep it separate from water, the calcium carbide represents a storage of a distinct amount of energy. We can afterwards use it for the production of energy by generating acetylene from the carbide and water and using the acetylene for lighting; and we may do this anywhere, since the carbide can be easily shipped.

These two examples, while simply given to illustrate the energy point of view, are also suggestive as to what we may expect from future electrochemical developments. The achievements of the past have given us new methods of storing and transmitting energy; they have enormously cheapened the production of known substances, like aluminum, and have given us new substances of great commercial usefulness.

In this respect the industrial development of the electric furnace is very instructive. As the pioneers of electric furnace work, the two brothers, Eugene H. Cowles and Alfred H. Cowles, have highly distinguished themselves, especially in the production of aluminum alloys. For the industrial development of the resistance furnace, the highest credit is due to the persevering work of Edward Goodrich Acheson. The extended laboratory researches of the French professor, Moissan, have thrown much light on the production of carbides.

The distinction between arc and resistance furnaces is so familiar that it is unnecessary to dwell on it here, nor shall details of design be discussed. But we may record the gradual change of the purpose to which the electric furnace is being put in practice. In the early days the intention was to produce as high a temperature as possible, and the result was the foundation of entirely new industries, like those of calcium carbide, carborundum and artificial graphite. For the production of these substances temperatures were required that could not be obtained by any other means but the electric furnace. In more recent years the intention has been rather to design furnaces so as to allow exact regulation of the temperature, and the electric furnace has thus been found suitable for reactions which do not require abnormally high temperatures.

The effect of regulating exactly the furnace temperature is very instructively shown by the example of treating a mixture of silica and carbon, which has been one of Acheson's fields of special research. By changing the conditions (by an appropriate design of the furnace so as to meet the special conditions of each case) it is possible to produce any one of the following substances: Carborundum, "white stuff," graphite, silicon, siloxicon.

The abnormal boom of calcium carbide in Europe, which naturally led to overproduction, resulted in various European furnace plants, originally erected for carbide, becoming free for other purposes. In looking for new processes it seems that nothing has more attracted the interest of European electrometallurgists than the possibilities in the electrometallurgy of iron and steel. Actual success has been achieved in the production of special steels (tool steels, crucible steel). A very great variety of arc and resistance furnaces have been developed for this purpose and in all of them care is taken to prevent contaminations of the bath from the carbon electrodes. Of special interest in connection with this latter point is the use of a resistance furnace, based on the induction principle, the fused steel forming the single secondary turn of a transformer, no electrodes whatever being used in this case.

While the above processes are all purely electrothermic, the most notable example of a combination of an electrothermic with an electrolytic process is the manufacture of aluminum. The electrolyte from which the aluminum is deposited is a solution of alumina in a bath of fluorides, and its discovery which made the manufacture of the cheap aluminum of to-day possible is due to Charles M. Hall in this country and to P. L. T. Héroult abroad; both arrived independently of each other at the same solution. By a recent court decision the electrothermic side of the process was held to be covered by the internal heating patent of Charles S. Bradley. What the electrochemical method of manufacture has done for aluminum is perhaps best indicated by the fact that the price of one kilogram was $250 in 1855, against 50 cents now. The Pittsburg Reduction Company has now something like 22,000 hp in operation for the production of aluminum, and it is evident that the greatest efforts are to be made to push the use of aluminum for all possible purposes.

Other examples of a combined electrolytic and electrothermic reaction are the production of metallic sodium by the Castner process of electrolyzing fused caustic soda, and the Acker process of producing caustic and chlorine by electrolyzing fused sodium chloride with a cathode of molten lead.

While the Acker process is the latest and one of the most carefully developed processes for the electrolytic production of caustic and bleaching powder, it is by no means the only one, since there is an abundance of processes in which an aqueous solution of sodium chloride is electrolyzed. We thus come to the class of purely electrolytic processes. Of course, Joulean heat and a certain electrothermic effect is here not absent, simply because it is impossible to avoid it. But it is generally so small as to be neglected, and, in fact, there are many cases in which it is necessary to make it small, since the output would be decreased by increased temperature.

One preliminary remark may be made on electrolytic processes in general. An electrolytic cell represents an electrochemical system and it is mostly possible to arrange it in such a way that when electrolysis begins we get the products which we want. But when electrolysis is continued we have no longer our original electrochemical system and the products of electrolysis may no longer be pure; we may now get something we do not want. The first condition that must be fulfilled for the successful working of an electrolytic process on an industrial scale is to have the conditions good at the start, to begin with pure solutions and to maintain them pure during electrolysis. As F. Haber says, everything can be accomplished with pure solutions; nothing with foul solutions. In many cases in which a process looked promising from the experiments made on a small scale in the laboratory, it turned out to be afterwards a failure on a large scale, because the electrolyte soon became impure and its purification required expense and the overcoming of difficulties which had not been expected in advance. The same fundamental principle of the working of electrochemical processes is expressed by D. H. Browne in a slightly more general form when he asserts that the keynote of success in electrolysis is to keep initially good conditions permanently good. Close experiment will almost always reveal the proper conditions under which certain work can be done, but the continuance of these conditions is attainable only by continual vigilance.

To return to the electrolysis of an aqueous solution of sodium chloride, the products of electrolysis are caustic soda and hydrogen at the cathode and chlorine at the anode. This is what is wanted if our final products are to be bleaching powder and caustic. But if we did not remove the caustic soda and chlorine from our cell we would have a new electrochemical system. The catholyte would then be a mixture of caustic soda and sodium chloride and the ions of caustic soda would participate in the conduction of the current and hydroxyl ions would travel towards the anode and produce new reactions. New reactions of a secondary nature would also be started by the mixing of the chlorine and caustic in the solution, due to diffusion and convection currents. It is thus clear that since our electrochemical system has changed we get new products which we do not want. The technical problem is, therefore, to keep the anodic and cathodic products of electrolysis separate from each other. It has been solved in three essentially different ways.

The first is to separate both compartments mechanically by a diaphragm. As an early pioneer of diaphragm processes, E. A. Le Sueur has been active in this country. The largest American plant using a diaphragm process (that of the Dow Chemical Company) is situated in Midland, Mich., while various diaphragm processes are in successful use in numerous paper and pulp mills, notably in New England.

The second general method is to keep the anodic and cathodic liquids separate from each other by making use of their different specific gravities (Glockenprocess, gravity process). This method is specially interesting as one of the comparatively few cases in which scientific research (in this case the determination of the transport numbers of the ions) has finally led to a new industrial process. While this process is in successful operation abroad, it has not yet been introduced into this country.

The third general method is to eliminate the sodium ions which are discharged at the cathode by alloying them with the mercury cathode. This process in the form developed by Hamilton Young Castner and C. Kellner is in use on a large scale in Niagara Falls. The elimination of the sodium from the cell by alloying it with a fused lead cathode in the Acker process is, of course, quite analogous.

In the manufacture of caustic soda and bleaching powder by electrolysis of sodium chloride, the electrolytic methods, sketched above, had to compete with one of the most firmly established chemical industries. The outcome of the war between the old chemical and the new electrochemical methods has been a victory for the latter, although the financial returns have been comparatively small, on account of the demoralization of the market.

While in the production of caustic and chlorine the purpose is to separate and maintain separated the anodic and cathodic products, just the reverse is the case when we want to obtain bleaching liquors or hypochlorites, since they are produced by a reaction between the chlorine and caustic. For this purpose it is evidently necessary to have the electrodes near together and to aid the above reaction by stirring. Several forms of hypochlorite apparatus are in use abroad, but have not yet found any extended use in this country. By modifying the conditions of operation, it is possible to produce chlorate, the main points being the use of a moderately high temperature and precautions for preventing reduction. This example shows how completely the results of a reaction may be changed, by varying the conditions, and it emphasizes the necessity, pointed out above, of carefully maintaining the original conditions of the system unchanged during electrolysis, if we invariably want to get the same results.

In electroplating, the problem is to have always a sufficient number of the metallic ions to be deposited, in close proximity to the cathode. The tendency of the current is to impoverish the solution near the cathode. This tendency must be counteracted. Stirring the solution and revolving the electrodes are suitable means and care must be taken to obtain proper corrosion of the anode which has to supply new metallic ions to replace those deposited at the cathode. There are now more than 1,200 electroplating establishments in the United States and in recent years a tendency has manifested itself to give up the old rule-of-thumb methods and to work according to exact principles.

Of much greater industrial importance, however, is the kindred art of electrorefining. In 1879 an experimental copper refining plant was in operation for a short time at Phoenixville, Pa., but the first commercial copper refining in America was erected in the early 80's. This is the Balbach works in Newark. To-day there are in operation in this country ten electrolysis refineries with a total daily copper output of 764 tons, or 279,000 tons per year. At the same time 27,000,000 ounces of silver and 346,020 ounces of gold are recovered per year in these refineries. (Ulke.)

There is a very peculiar difference in the details of operation of the different refineries. Two plants use the series arrangement of electrodes, all others the multiple system. There is a considerable difference in the current density used; of two plants in the West, in close proximity, one uses 40, the other 12 amperes per square foot. The list of variations in the method of operation could be easily enlarged. In other words, the art of copper refining is far from being standardized. Since it is known that for a number of years the different refineries have very carefully and systematically studied the best conditions of operation in their own case, the difference in the methods of the different refineries may be attributed to a difference in the given conditions in each case. If this is so it emphasizes the complexity of the economical working of even so simple an electrolytic problem as copper refining.

Recently the Betts process of lead refining has aroused very great interest. The essential point is the electrolyte, which is a solution of lead fluosilicate, containing an excess of fluosilicic acid. It is easily prepared from inexpensive materials, it conducts the current well and it dissolves other metals but lead only in very small quantities. The last point is of great importance in view of the fundamental requirement that the solution should remain pure during operation. In a similar way, for copper refining the possibility of continually renewing the electrolyte is essential.

The Wohlwill process of gold refining is in operation at the Philadelphia Mint, using an electrolyte of gold chloride, rather strongly impregnated with free hydrochloric acid. The addition of the free hydrochloric acid in this case, like that of fluosilicic acid in the Betts process, is necessary to produce the proper corrosion of the anode and to maintain the electrolyte in its original condition. Much special study has been devoted in recent years to the question under what conditions dense solid cathodic deposits of metals are obtained. The simple method by which, in the case of lead, Betts overcomes all difficulties in this respect—by providing a reducing action, practically accomplished by the addition of gelatine or glue—seems very encouraging.

As the reverse case of electroplating, we may consider the electrolytic stripping of metals. The production of tin from tin scrap has achieved considerable commercial success, first in several plants in Germany, from where it was recently imported to this country. An interesting similar process, although of much less industrial importance, is the method of Burgess, which was used in bicycle manufacturing works for removing the thin layer of brass on the surface of the frames by electrolysis, with a sodium nitrate solution as electrolyte. This example is mentioned to show how electrochemical methods may be applied to details in various manufacturing processes and may effect an important economy of labor.

In their application to the metallurgy of gold, the use of electrolytic methods has been confined to the cyanide process, as far as commercial success has been obtained. Electrolytic precipitation has been used successfully in the Siemens & Halske process in South Africa, although side by side with zinc precipitation. The latter method is nearly exclusively used in this country. But it should not be overlooked that the latter method is also essentially an electrochemical phenomenon. Chemically pure zinc is inactive as a precipitating agent. What is needed is commercial zinc containing small particles of impurities, or specially prepared zinc couples, like zinc-lead. Thus, while with electrolytic precipitation we have the source of the electric current outside of the precipitating vat, we have with zinc precipitation an immense number of small short-circuited galvanic couples in the precipitating vat itself.

In the production of metals from ores, much research has been devoted to the problem of getting copper and nickel from the Sudbury ores. The late Dr. Hoepfner did highly valuable pioneer work in this line, but full commercial success was obtained by David H. Browne, who, in working out his process in which chlorine passes through an ingenious cycle, paid proper attention to the fundamental requirement that pure solutions must be provided and maintained.

An interesting and novel electrometallurgical process which, however, has not yet attained industrial importance, is Salom's reduction of lead from galena by direct cathodic reduction.

That class of processes in which chemical effects are produced by discharges through gases is the youngest in the development of industrial electrochemistry. Commercial success has been achieved abroad with the production of ozone from air and the subsequent use of ozone for sterilizing water. If the cost is not prohibitive, there should be a commercial future for such processes in this country. Great interest has been aroused by the Bradley-Lovejoy process for the fixation of nitrogen from the air. The process is still in its experimental stage and a successful issue would have a revolutionary effect in many branches, particularly in agricultural chemistry. The variety of possible methods is indicated by the utilization of the silent discharge in ozonizers, while Bradley and Lovejoy produce arcs, but so finely subdivided as to give a large surface for small energy.

This cursory review does not nearly exhaust the subject of producing chemical effects by electrical means, but it is hoped that it gives at least a general idea of the achievements of the past and of the possibilities of the future, together with some general principles which should always be kept in mind in connection with this subject. We may be permitted to treat even more briefly the reverse problem, that of producing electrical from chemical energy.

There is not much to be said concerning primary batteries. Their limitations, if zinc is used as "fuel," have been pointed out above. The problem has, therefore, been to substitute carbon for zinc and to devise a "carbon cell." The effect would be commercially far-reaching. At present we burn the coal in connection with boilers, steam engines and dynamos and thus produce electrical energy by a roundabout method, with a low efficiency, since the efficiency of the steam engine is limited by the principles of thermodynamics. There would be no such limitations with a carbon cell. But the trouble is that such a cell is still a dream. Theorists and "practical men" have attempted the solution of the problem, but have equally failed.

On the other hand, storage battery engineering has passed with success through an extremely active career and the outlook is bright for the future. As early as 1856 Gaston Planté began his extended investigations on the formation of the lead accumulator. His method was purely electrochemical. Starting with metallic lead sheets, he submitted them to the action of the electric current in dilute sulphuric acid. But since the cell had to be charged and discharged a great many times, his method of formation required a very long time and was expensive. The technical problem was, therefore, to shorten the time of formation.

Faure abroad, and Brush in this country, devised in the early 80's an improvement of the Planté cell, which consisted in mechanically applying active material to a conducting support. They thus produced instantly a plate, the manufacture of which by the Planté process, would have required several months. Immediately afterwards an extreme activity began in storage battery invention, the goal being to avoid the claims of the Brush patent. The outcome was a modification of the original electrochemical Planté formation by replacing the electrolyte of pure dilute sulphuric acid by an oxidizing electrolyte. Moreover, purely chemical formation without any current was also found practical.

Along these general lines the successful lead battery of to-day was developed. The number of United States patents on this subject is legion, but the patents generally refer either to details of construction or to composition of the electrolyte for formation. Storage batteries have found very extended use in direct-current central stations and sub-stations. In fact, stationary batteries for such work represent at present 75 per cent. of all the storage batteries manufactured, and for this purpose the position of the lead cell seems secure.

In recent years, however, the possibilities of electric automobilism have encouraged inventors to search for a battery of light weight and small size. The use of lead was considered as essentially unsuitable for this purpose. The researches were mostly made along the lines of alkaline batteries. Finally the aim was the design of an "oxygen lift" cell, with potassium or sodium hydroxide as electrolyte and electrodes simply undergoing oxidation and reduction and insoluble in the electrolyte in all states of oxidation. Several inventors have worked along this line, among them Jungner. But commercial success was first attained by Thomas A. Edison with his nickel-iron battery, which, it seems, will have a field of its own, especially for automobile work.

A Quarter Century of Electric Lighting.

By Dr. Louis Bell.

The growth of a new art is a startling phenomenon. The familiar manufacturing enterprise of a nation may, under normal conditions, be expected to keep pace with the growth of the population in numbers and in wealth and save for commercial disaster now and then, or for artificial stimulus by governmental action, to move forward at a fairly regular rate. But the irruption of a new art like electric lighting is a very different matter. It grows in response to a law of demand that bears no definite relation to anything and while, of course, this growth is affected by local causes and by the conditions of general prosperity, it depends largely upon intrinsic factors in the art itself, the effect of which cannot be predicted, but becomes visible in the fullness of time.

One may study the phenomena of such growth as a pure matter of statistics, but while such an examination may, like other statistics correctly show effects, it fails utterly, as statistics usually do, in showing the causes which produce them. Cause and effect can be correlated, but only by studying the circumstances which are concurrent with the figures. The relations between figures and facts are far too complicated to be self-evident.

Starting then with the broad facts that less than twenty-five years ago incandescent lighting by central stations began, and that to-day the whole business occupies nearly 3,700 stations, represents an investment of more than half a billion dollars, and draws a gross yearly income of nearly ninety million dollars, it is worth the while to attempt to trace the reasons for so prodigious a growth and the factors which have gone to produce it.

In that quarter century the population of the country has increased about 80 per cent., and few large industries have greatly exceeded this rate of growth; but electric lighting starting from absolute non-existence has risen to an industry of the first rank in the face of strong competition from other illuminants, and what is more, in the face of a cost which throughout its whole early history was undeniably higher than that of any other illuminant. It has made its way through the operation of favoring factors other than economy, ranking as a luxury rather than a necessity, and only within a few years being able to meet competition on the simple basis of cost. These facts are very unusual in the history of a great industry and deserve careful consideration. They are the more extraordinary when one considers that for some years electric lighting was not only upon the whole the most costly but the least reliable form of illumination, was fought viciously by the fire underwriters, suffered from ferocious internecine strife among its exponents and had been a very Gettysburg of patent litigation.

When late in 1879 the incandescent lamp appeared as a commercial possibility, the arc lamp had already been for some years in slowly increasing use both here and abroad, mostly for small private installations, for the quite sufficient reason that the largest arc dynamos would handle but a few lamps, not enough to cut any figure at all for anything but the smallest plants. Nevertheless it was perfectly evident that the arc had come to stay. It had the inestimable property of giving white light in the form of a very intense and powerful unit. Before the electric arc came into use, lights of similar power were practically non-existent, and the arcs could therefore give a brilliancy of effect previously unknown. This fact of itself accounted for their rapid growth in popularity and when their accurate rendition of color values is taken into account it is small wonder that they made a sensation. The Jablochkoff candle, practically the earliest commercial form of arc, was, in spite of its limitations, altogether remarkable in the quality of the illumination given, and, in fact, would be difficult to surpass in this particular. It is interesting to note that it has continued in limited use even up to the present time.

The arc lamp therefore did the pioneering for the incandescent lamp. It educated the public to the appreciation of the importance of color values in illumination, drew once for all a line between weak illuminants and powerful ones, and caused all eyes to be turned to electricity as the coming source of illumination.

Then came the incandescent lamp in response to the demand for smaller electric lights. The subdivision of the electric light was the problem of the day, and very fortunately this problem was solved by the glow lamp instead of by arcs of small candle power, which could not then have been, and, in fact, never since have been, satisfactory illuminants. The incandescent lamp nearly equalled the arc in rendering color values, and enormously surpassed it in convenience and steadiness.

It was far less economical than the arc and was not for some time on public circuits able to compete with gas, but it made its way by reason of its better color, its steadiness and its freedom from vibration of the air, and from overheating. These good qualities carried it ahead in spite of all opposition. It is hard to realize to-day how much these gains meant in interior illumination, but they were fully realized at the time and they unquestionably won the day for electric lighting. Looking over some ancient history recently the writer came across a printed letter reporting results from one of the early isolated plants, that in the Pemberton Mills, installed in October, 1881. Although in this case two 4 ft. gas jets were replaced by each "A" lamp of 16 alleged candle power, a great improvement was noted in the conditions of illuminations, especially with regard to color vision in work on colored fabrics, and in the purity of the atmosphere. Further, it was shown that the cost of the electric light, including interest and depreciation at 12 per cent. and lamp renewals at a dollar apiece, was less than the cost of the gas for the burners replaced by more than a half.

One smiles nowadays at the idea of replacing two 4 ft. gas jets by one 16-cp lamp, but the fact of doing so was a valuable lesson in illumination, proof that a steady light, good in color, can actually with positive advantage replace lights of greater gross intensity, but lacking these two things.

A good many people who ought to know better have not learned this lesson yet and still foster the idea that illumination intrinsically bad can be made good merely by increasing its quantity.

The incandescent lamp practically won its way through quality, for only under rare conditions could it at first show economy over gas at the prices generally current. Once introduced and appreciated it was rapidly pushed ahead. It was a thing to advertise in one's business and to brag about to one's neighbors, and its use thus spread with the added momentum due to fashion. With it came increased use of arc lamps, partly in competition, but still consistently backing up the public demand for bright light and more of it. Pretty bad some of those early arcs were, too, but they did what gas never had done—they really lighted large areas effectively by dint of sheer brilliancy. Between the arcs and incandescents there was awakened a demand for public electrical supply, though, by a strange freak of fate, the arc and the incandescent systems, beautifully fitted to supplement each other's work, fought like cat and dog, damning each other with an ingenuity of objurgation that would be worthy of a unique position in profane history. Apparently this mutual abuse served simply to make violent partisans, and both systems flourished. Forward steps were rapid, and on the one hand arc machines carrying a respectably large series of lamps soon came into use, and the carbons, at first horribly bad, were so improved as greatly to better the steadiness of the light. On the other hand, the incandescent lamps were greatly improved in manufacture so that their useful life was largely increased, the bamboo filament was fashioned into as good practical working form as its nature permitted, and the invaluable three-wire distribution was brought into wide use. In large cities incandescent lighting was giving good account of itself in competition with gas, but it was not yet able on account of the inherent limitations of a low pressure distribution to work advantageously in the smaller places where absence of competition from gas would give it an advantage. At the present time more than three-quarters of the central stations are in such places and have the field to themselves.

Desperate efforts were made, with indifferent success, to build up an incandescent lighting business on arc circuits. Such lights have never been wholly satisfactory even for street lighting, and the danger of high potential wires kept them for the most part out of buildings. The greatest impetus that the art of electric lighting received after the invention of the incandescent lamp was the introduction of the alternating-current transformer system in 1885, when the first plant went into operation in Great Barrington, Mass. The next two years saw the system put into practical shape, and thereafter the growth of small stations was startlingly rapid. The number of new plants started in 1885 was but 55, the next year it was 100, the next 147, the next 160, and in 1889 it arose to 208. A large part of this activity was represented by small alternating-current plants. Bad as they were from our modern standpoint, their old 50-volt lamps did good service, for they were far easier to turn out successfully than the more delicate 110-volt lamps of the direct-current system. It is interesting to note that in some of the very earliest Edison plants 8 and 10-cp lamps were freely used, but difficulties of manufacture and the customary gas standard of 16-cp soon forced the small lamps out of use only to reappear years later.

Meanwhile, arc lighting had prospered, machines capable of operating forty lights or so in series had come into use; the lamps were of far better quality than before; and, reinforced by the power of working an incandescent system with alternators, the old arc stations took on a new activity. With the alternating system, too, came alone by stress of competition, various improvements in incandescent lamps, including the flashing process now universally used, and Mr. Weston's structureless cellulose filament, now, after various modifications, in universal use. These improvements are the basis of scientific lamp manufacture, and the fierce fight that was waged between the natural and artificial filaments now seems a curiout bit of ancient history. The first ten years of central-station lighting, with their ferocious strife of "systems" were years of tremendous progress, and desperate competition, often unwise and injurious, but serving to keep the art moving forward and strengthened its hold upon the public.

Fortunately, the one great improvement in gas lighting, the introduction of the incandescent burner, had not yet come to active service, else electric lighting would have had a far harder struggle for existence than it actually found. And when the incandescent burner actually did come into competition with electric lighting, its life was so uncertain and its color so vile that it made small headway until electric lighting was in better shape for hard fighting. Even now, in spite of repeated alleged improvements, the color of the incandescent gas lamps is ordinarily so bad as to put them at a hopeless disadvantage.

But better things were in store for electric lighting. The war of "systems" drew to a close by the crippling of some combatants and honorable truce among others. The electric railway had come to strengthen the hands of the electrical industries in general, and the troublesome problems of alternating-current distribution, of proper insulation for machinery and for lines, and of machine design, were being rapidly threshed out. There is no absolute dividing line between the old and the new, but about 1890 electric lighting took a firmer hold and began the period of its most effective growth.

The period was not signalized so much by brilliant discovery as by the application of sound common sense. The first step of importance was the introduction of large dynamos, generally direct-coupled. Although direct-coupling had been tried by Edison in the very beginning of central station work, dynamo design was not then far enough advanced to ensure success, but these later direct-coupled units revolutionized the central station business, simplifying problems of distribution, improving regulation, increasing station efficiency, and generally putting incandescent electric lighting on an economical and business-like basis. Arc lighting, too, was proceeding on broader lines with larger units, and presently came the successful constant potential arc, putting it in the power of the incandescent lighting station to do all classes of business over the one network. This unification was perhaps the most important step that has been taken in central station practice, and it immediately gave electric lighting an economic lift that was very quickly felt. It became possible to put prices at a point that attracted business, and in the early nineties not only was building active, but there was an extensive course of rebuilding and change of equipment which really inaugurated the modern period of electric lighting.

About ten years ago the idea of unification of service was extended to alternating-current practice by the introduction of polyphase apparatus. The first applications were to power transmission plants, which did not in themselves affect the lighting industry very greatly; but a little later the very extensive adoption of polyphase transmission in central station working via sub-stations rose to great importance in increasing the facilities of the large urban plants. At the present time more than 60 per cent. of the total dynamo capacity in the central stations of the country is in the form of polyphase and other alternating-current generators. The introduction of these big modern alternators has enabled conditions of good regulation to be maintained on alternating-current distribution systems, and has, by improving the service, greatly stimulated incandescent lighting on such systems. The substitution of large transformers feeding secondary mains for the house-to-house distribution has also had a most important effect in improving business and in increasing station economy so as to give more encouraging financial returns.

Arc lighting was much less stimulated by these changes than was incandescent lighting, for the alternating arc has never obtained a firm hold upon public popularity. Nevertheless, about 30 per cent. of all the arc lights are to-day operated by alternating current, a proportion which is due to secondary rather than to primary causes. The incandescent lamp has undergone in these years a far less extensive evolution than the arc lamp. It is now pretty nearly the same thing that it was ten years ago, save that improvements in manufacture have rendered the product somewhat more uniform. Chief among these we must reckon the almost universal use of the squirted cellulose filament and the introduction of the chemical method of final exhaustion. Various efforts have been made to introduce incandescent lamps of about double the usual voltage. The difficulties of construction of such lamps, their relatively low efficiency and the ease with which an alternating distribution at the usual voltages is effected constitute ample reasons for the small use of these high-voltage lamps; while the vigorous objections of the fire underwriters have discouraged any extensive exploitation of them.

The greatest change of recent years in general lighting has been the introduction of the enclosed arc lamp, which has worked a revolution in indoor lighting at constant potential as well as in street lighting. It has on the whole stimulated incandescent lighting, however, by raising the common standard of brilliancy, and by aiding in the unification of service. Considerably more than half the arc lights in use are enclosed, the bulk of the open ones being used for street lighting by companies not yet quite ready to undertake re-equipment. Of the alternating arcs more than nine-tenths are of the enclosed type, a result due almost to necessity. The introduction in recent years of series alternating arcs fed from constant current transformers is responsible for most of the use of alternating-current arcs, and practically all such are enclosed.

Through all these years of progress the incandescent lamp has held its own and has grown in relative popularity. The same virtues that gave it its start in life have kept its fortunes in the ascendant. With all its failings in points of efficiency it is to-day, as it was in the beginning, the best available illuminant in point of quality and general usefulness. Within very recent years determined efforts have been made to obtain other electric lamps of equally good qualities and of higher efficiency, but up to the present these efforts have not been crowned with success. The Nernst lamp, most admirable in some respects, is at its best in competition with the arc rather than the incandescent lamp, and is still a rarity, not yet seriously to be considered in the grand total of electric illumination. The mercury arc, another recent candidate for lighting honors, has little yet to show in the way of results, and its color is so hopelessly bad that unless remedied by some very radical step, the lamp will entirely fail of material usefulness as a general illuminant. If the public could be educated up to the point of liking the color of the mercury arc, it would already have welcomed the incandescent gas mantle to the exclusion of nearly everything else.

The incandescent lamp is then to-day as it has been all through its history, the mainstay of modern illumination so far as interior lighting is concerned. It may in due season be supplanted by something better, but that something will have to be equally steady and simple and convenient and good in color. At the present time there are nearly twenty million incandescents in lighting service from central stations in this country alone—how great a harvest from the seed time of 1879! Electric lighting has won its way into the front rank of American industries, and there it is likely to stay. Its full history cannot be written apart from that of the country's industrial growth with which it has more than kept pace.

The Development of Industrial Photometry.

By Prof. C. P. Matthews.

The science of photometry from an industrial and commercial standpoint has passed through two periods of marked stimulus. These periods have been contemporaneous with the development of the gas industry and the development of the electric light, respectively. The development of the incandescent lamp with the necessity of careful candle-power ratings, especially, has resulted in improved photometric methods. Apart from the growth and improvement of the science due to the causes just mentioned, there has been a more or less steady improvement in the physical laboratories of the world.

Notwithstanding the great improvement that has been made both as regards accuracy and speed, it must be said that until quite recently there has been a widespread tendency to regard photometric results as of very doubtful accuracy. People have grown to look askance at all candle-power measurements. Unfortunately, there has been much to justify this scepticism. Photometric results have been widely at variance. Three causes have contributed to this condition. (1) The lack of a satisfactory primary standard of light. (2) The failure to take into consideration the many sources of error in the actual process of measurement. (3) In many cases the fluctuating character of the thing to be measured. The question of a standard of light cannot be dealt with here. It may suffice to say that while the problem of a satisfactory primary standard seems far from solution, the matter of preparation and distribution of carefully-prepared secondary or working standards is being well taken care of. The Electrical Testing Laboratories in New York are prepared to issue seasoned and standardized glow lamps, which yield a candle-power in close accordance with the Reichsanstalt standards. The National Bureau of Standards at Washington is prepared to certify the standards in terms of the same unit. The action of the American Institute of Electrical Engineers, provisionally defining the British standard candle as 1/.88 Hefner units has done much to relieve the situation of doubt and uncertainty.

With reference to the errors that creep into the actual process of measurement, it may be said that, although photometry is simple in theory, it requires no little skill and judgment on the part of the operator. The science has undoubtedly suffered from the idea more or less prevalent that almost anyone can make photometric measurements.

As to the third cause of inaccuracy, it may be said that in many cases the attempt is made to measure the candle-power of a source which fluctuates in brightness in the measured direction between wide limits. Ordinary arc light photometry furnishes a good example of this. It will readily be seen that attempts to assign a fixed value to a quantity so varying as the light emitted in a given direction from the arc, would yield discordant results unless the readings are extended over a long period.

The photometry of artificial light sources may be considered under two heads: (1) Ordinary photometry, or such as deals with the integral brightness of the source; (2) spectro-photometry, or such as deals with the distribution of the brightness throughout the spectrum. Only the first-class of measurements will be taken up in this article. In considering the measurements that fall under the head of ordinary photometry, it is evident that the subject might properly be taken up under more than one classification.

We will first consider the subject from the standpoint of the relative accuracy of the results obtained. In this respect we may distinguish (1) work requiring and receiving the highest possible experimental skill. Under this head would come the study and comparison of the various primary standards of light. Naturally, in such work the highest obtainable accuracy must be aimed at. Every condition affecting the problem in hand must be studied with a view to ascertaining its importance and the correction for or the elimination of its effect. (2) Work requiring careful and conscientious measurement, but not necessitating the same degree of skill as that just mentioned. Under this head would come preparation of secondary or working standards of light in the shape of carefully seasoned and tested glow lamps. Thanks to the constancy which can be obtained in a set of carefully intercompared lamps, it is altogether possible to maintain a temporary standard of light with all necessary accuracy. Indeed, it has been shown by Sharp that copies of the arbitrary standards set up in this way can be produced with considerable greater accuracy than it is possible to secure in maintaining the best primary standard known to-day. An indefinite number of these copies can be made and placed in the hands of those requiring working standards of light. Thus, pending the development of an invariable primary standard, we shall at least be in fair accordance as regards our working standards of light. And furthermore we shall have the means at hand through the National Bureau at Washington of checking our standards at any time.

The subject of ordinary photometry may also be subdivided according to the character of the measurements. These may be either unidirectional or integral. Early photometric measurements were entirely of the first class. Experimenters were content with candle-power in a single direction, usually horizontally and normally to some specified aspect of the source. For example, the candle-power of a gas flame is understood to be the result of a measurement made in a direction normal to the broad side of the flame. A similar measurement was applied to earlier forms of the incandescent lamp. Measurements of this kind are necessarily a basis of all curves of candle-power distribution, and hence are an invaluable aid to the study of artificial light sources.

The simplest example of the second-class of measurements is the determination of the mean horizontal candle-power of an incandescent lamp by making a photometric setting while the lamp is spun on a vertical axis. Lamps are rated commercially to-day by this method. Obviously, the method is applicable to any source which can be rotated at the required speed without altering its light-giving value. The determination of the mean spherical candle-power of a light source at a single setting furnishes another example of an integral measurement. By means of the apparatus developed by the writer, it is possible to make the spherical measurement with all the ease and celerity obtainable in the simplest photometer setting. Moreover, the accuracy of such measurements is as great as that to be secured in the longer and more laborious methods. It is not, perhaps, out of place to say that a form of the apparatus less expensive than that originally put out is now being introduced.

The Unchangeableness of the Three-Wire System.

By Charles L. Edgar.

I do not suppose that, in the history of the world, there has ever been an industry which has shown such tremendous growth in a quarter of a century as that with which your paper has to do. To say that you not only have kept the pace, but have actually made the pace many a time is, I think, a compliment which is your due. You are to be congratulated on your work and we are to be congratulated that our industry has such a paper.

On looking back over the years there is, in my mind, one thing that stands out above all others, and that is the unchangeableness of the Edison three-wire system of distribution. If we look back to 1883 and go over the plans of the Sunbury station, especially its switchboard connections, its feeder system and its distribution of mains, we will see that it is an exact duplicate, in miniature, of what is now being used in the large cities of the country. Changes due to the enormously increased quantity of current have been very great, but the fundamental principles laid down by Mr. Edison a quarter of a century ago are still recognized to-day in designing all comprehensive systems of distribution. It is perfectly true that instead of locating small steam stations at regular intervals throughout the city, as was done in the early 80's, we are manufacturing our electricity at high tension at a distance and transmitting it to what are now called sub-stations, but from that point on the quarter of a century has changed only the details; the principles are the same. Even in details, the changes are less than one would imagine. The feeder regulator has given way to the multiple bus; the mains have become larger and the feeders, relatively speaking, fewer, as time has gone on. The wires have been taken down off of poles and put underground; the catch box of to-day is an exact duplicate, in theory, of the distributing pole of the Sunbury days. It is merely underground, carries more current and has a few more refinements. The low-tension switchboard of the modern station of to-day was designed in 1882 and has only been multiplied a hundred times. So we could go on, item by item, and a whole book could be written, all going to show that in the wonderful advance which has been made in an industry which is to-day one of the most prominent in the world, the three-wire system stands unchanged—a monument to the genius of Mr. Edison.

The First Electric Street Car in America—1884.

BY E. M. BENTLEY.

ON July 27, 1884, an Associated Press dispatch was sent out from Cleveland, Ohio, as follows:

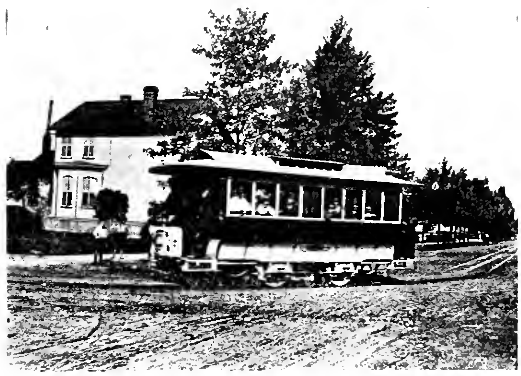
"The first electric railroad for public use in America went into operation in this city yesterday in connection with the East Cleveland Street Railroad Company, which has just completed a mile road. The experiment was so successful that the company expects to change its entire system, comprising over 20 miles, into electric roads. The Bentley-Knight system was used and the current was carried on underground conductors laid in conduits like those of cable roads. The cars were started and stopped and reversed with the greatest ease. Any number of cars up to 15 can be run at one time on a single circuit and from one machine, which is a result not attained by any of the European systems now in operation. The success of the new road has made a great sensation in both street railroad and electrical circles, and is expected to greatly extend the field of electrical development, as well as enhance the value of street railroad properties."

The occasion for this enthusiastic dispatch—which is not without some prophetic truth—was a single electrically-driven street car, that had for many years traveled up and down the streets of Cleveland behind two car horses, such as are now happily obsolete. Going back fifty years or more, we find many instances, both in this country and abroad, of scientific toys, comprising a small motor mounted on a truck and supplied with battery current through the track rails. Indeed, the advent of the battery as a source of current gave rise to many suggestions which we have only seen realized in recent years. Prior to 1884 Mr. Edison had also constructed his well-known pioneer roads at Menlo Park, N. J., one in 1880 and the other in 1882, in both of which one track rail had served as the outgoing and the other as the return conductor of the circuit. Mr. Daft had also been experimenting, having operated a short length of track on the pier at Coney Island in 1884, while in 1883 he made a few trips with an electric locomotive drawing a passenger car on the Mt. McGregor Railway near Saratoga. He, too, employed the track rails for his respective conductors. Indeed, he once took out a patent on an electric railway, in which the novelty lay in the low potential which he purposed to use; 30 volts was the upper limit of his low potential and the rails were to be "practically uninsulated." This is mentioned in passing to indicate what a blank wall of inexperience confronted the early experimenters. Mr. Edison was then dreaming principally of a high-speed road from New York to Philadelphia and Mr. Daft's efforts were in the same direction. Many other projects of that date seem even more preposterous in the light of our present knowledge.

Mr. Knight and myself, perhaps more than others at that time, were impressed by the fact that the immediate need for electric railways was in the city streets, and that the use of one rail as a positive and the other as a negative conductor, or even a live third rail, was not feasible for this purpose. There was also an active agitation then in progress against overhead wires, and so we undertook at once the development of our ideal, namely the conduit system, or, as it is now usually known, the underground trolley, quite unconscious that we were extremely premature.

The street car track of those days was simplicity itself, and it was several years before the average street railway superintendent could be brought to believe that an electric car deserved anything but the worst piece of track on his road. The ties were first laid down 5 ft. apart and upon them were placed the two longitudinal wooden stringers 6 or 8 in. in depth and upon the stringers were spiked strap rails, weighing 35 or 40 pounds to the yard. The switches were merely cast-iron plates inserted at the branching points of the track. There was a prejudice against movable tongues on switches. In some of the more elaborate roads tongues were employed, operated by a tilting table, the horses walking on one side or the other of the table to throw the switch, but more commonly the horses would be turned to one side or the other of the car to drag it laterally across the switch plate to make it take one or the other of the two branching tracks. An objection gravely urged against electric cars was that there would be no horses to pull the cars sideways at the switches or to walk on the tilting table. This track construction, although universally used, deteriorated rapidly. The surface of the stringers, being alternately wet and dry, soon rotted and invariably rotted in spots so that the flexible strap rails quickly assumed a wave form, and the light cars, with their short wheel bases would go bobbing along like a ship at sea. The outfit of the repair gang was correspondingly simple, comprising an adze, a crow-bar, a sledge hammer, a bag of spikes and a bundle of "shims." It was an easy matter to pry off a rail, adze off the rotten surface of the stringer, lay in a "shim" and spike the rail in place again. I have referred to this matter to indicate the nature of the conditions encountered by the pioneers of the electric railway, it being manifest that electric railroading on a track of this description was no easy matter. It was, however, but typical of many other difficulties besetting the situation.

It was on a track of this kind, along a section of the line of the East Cleveland Street Railway Company, that the car in question was first operated. The route began on what was then known as Garden Street, two blocks west of Wilson Avenue. From Garden Street it turned into New Street, and then into Quincy Street, and was at first about a mile in length, but was soon after extended across the Cleveland & Pittsburg Railroad tracks and thence along Quincy Street to Lincoln Avenue. The conduit was of wood, excepting about 100 ft. at the crossing of Wilson Avenue, which was of iron. Rectangular cast-iron yokes were set on the ties and outside of the yokes were two-inch planks, set on edge to form the sides of the conduit, while similar planks formed the top, with a slot having an original width of three-quarters of an inch. Inside the conduit



FIRST ELECTRIC STREET CAR, CLEVELAND, OHIO.

were the conductors, formed of channel bars about four inches apart and supported on insulators projecting from the wooden side walls of the conduit and entering the groove in the rear of the channel bars. On this crude line of construction there were worked out several curves, also the branches for a turnout and for one spur track and—most difficult of all—a railway crossing through the Cleveland & Pittsburg tracks. The current for the road was supplied at first from a Brush arc light machine, No. 7, driven by a 25-hp engine in the car barns at Euclid Avenue, a quarter of a mile away, and to one old gentleman, a director of the road, it was a constant source of wonder that, after throwing the switch, it took such a short time for the current to come from the car barns to the road. The first car was equipped with another Brush arc light dynamo, No. 6. It was suspended directly underneath the center of the car body, the shaft extending across the car. On the driving end of the shaft were two pulleys, each having a series of half-inch grooves in its face and from these pulleys belts of coiled steel wire extended in opposite directions to counter-shafts on each end of the car, which, in turn, were similarly belted to the axles. This mode of gearing had been the outcome of considerable experiment, and it must be said that, for a few days, the operation was all that could be desired, there being no slippage of the belts, while there was a yielding spring start which was easy and agreeable. In the course of a week or two, however, the springs were breaking with a loud report, at the rate of about one an hour, and, until the passengers got used to it, there was a serious commotion among them each time that it occurred. At first the breaks were at the couplings, but when this was finally overcome the wire itself began to give way, indicating that, for steady work, the duty was too severe, crystalization of the wire resulting in a short time; nor could it be obviated by any kind of wire then available. The belts were, however, kept going until a second car was equipped with a different transmission scheme. On this car the motor shaft was equipped with a friction wheel made of discs of strawboard solidly compressed. Outside of this pulley and around it were grouped three similar pulleys, one of them larger than the other two, and outside of the three was a shell, the four pulleys having a sort of eccentric compression against the shell, without strain on the bearings, and the shell was mounted on a separate shaft and connected by link belts to the car axle. This device likewise worked well for a time, but one day the friction wheels began to slip under a heavy load, developing flat spots at once and the usefulness of the contrivance was at an end. A third car was then equipped with spur gearing, the body of the gears being built up of paper like a paper car wheel. By this expedient the noise of the gearing—which had been one of the reasons for not employing spur gears at first—was deadened to a satisfactory degree. The motor shaft had a speed of 1,500 and we could find at that time no precedent for the use of spur gearing at that speed. In this third car the motor was carried by a separate truck, its shaft lying longitudinally of the car and gearing with a parallel counter-shaft, which drove the two axles by bevel gearing. This eliminated for a time the difficulties involved in the mechanical transmission between the motor and the car.

The regulation of the motor and its reversal was extremely simple so long as we were working with a constant current, it being only necessary to move the brushes around the commutator both for reversal and for speed adjustment. From the brush-shifter a rod extended to each end of the car where, by means of a simple lever, the entire control of the car was secured. We had, at the outset, been possessed with the idea that the cars might be operated in series with a constant current, a scheme which was quickly abandoned by us, although a few years later Mr. Short, in Denver, made a brave attempt to operate such a system and succeeded in running six or seven cars in that manner. It should be said that the series arrangement was our plan for long-distance and high-potential work, though we gave it a brief, but unsuccessful, trial on our Cleveland road. Lest the new generation wonder how street car motors were to be operated in series, I give here a diagram of our circuits:

RAILWAY MOTORS IN SERIES.

Mr. Short, on the other hand, used the form devised by Fleeming Jenkin, who was the first to propose the series system. The line was divided into sections shorter than the length of the car with a spring jack between each section and its neighbor. On the car was a plow, as long as the car, and serving, in effect, as a plug for the jacks, taking into a jack ahead before leaving the jack in the rear.

After giving up the idea of constant-current operation, there followed a long chapter of experiments for the working out of motor-regulating devices for constant potential, which culminated in the contrivance of a regulating rheostat of sheet-iron plates in superficial contact, such as was afterwards used by the Thomson-Houston Company up to the time that the series multiple method was brought into use, about 1892. It should be remembered that constant-potential circuits at 500 volts were then unknown, and that there was little or no precedent for the control of motors of the size needed for railway work, even on 100-volt circuits.

Another source of serious tribulation was the plow for maintaining connection between the car and the conductors in the conduit, this problem being intimately associated with the matter of the bad roadway, which at that time appeared to be indispensable. It seemed necessary to anticipate that a car would jump the track at least once a day, and, whatever the future might have had in store, it was then an absolute requirement that a car should be permitted to leave the track as frequently as it desired without wrecking the plow. This point having been established, we met the situation by means of a plow so constructed that it could be thrown out through the slot at any point and so hung on the car that it would be tripped and swung up out of the conduit, if it encountered any obstruction such as the end of a loosened plank on the conduit, or if it should bind in the slot when the car went off the track. Manifestly, the requirement that the plow should be capable of coming out through the slot imposed limitations on the size of its parts and in consequence there was liability of breakage while, moreover, with such insulating materials as were then available to the art a "ground" was not unknown. It was only after the art was so well advanced as to make it reasonable to expect a car to stay on the track, that the construction of a substantial and reliable plow became feasible. It was some years, however, before electric cars were deemed worthy of having a new track laid for them. It was considered their duty to travel on any old track that might happen to be already on the ground. It may be mentioned that the "plow" originally received that designation from the fact that in one of our earliest schemes, which fortunately was never attempted in practice, the top of the conduit was made up of hinged sections that were to be lifted as the car proceeded by means of a device which was naturally designated as a "plow," a name which has since clung to it.

The success of this road, as a factor in actual service, was really greater than might have been expected. At first the passengers coming up from down-town transferred to the electric car and were taken by it to the end of the route, while, after the third car was in use, it took the horse cars through as trailers. A week or ten days of uninterrupted service would be followed by several days of repair work. The object of the enterprise was, however, to test out the value of different devices by subjecting them to service conditions, and not to do the actual work of the railway. Winter running was particularly uncertain, but we demonstrated the ultimate possibility of it to our satisfaction. The road was operated for over a year, but the construction was, in its nature, temporary. Besides the wooden conduit, the streets through which we ran were sewerless, and about to be torn up, while we were then unprepared to replace the wooden conduit with a steel one or to provide the additional material required for a permanent plant, even if it would have been commercially warranted in that location. There were also people who could not be brought to believe that a Brush arc light dynamo was not an ideal railway motor, or was susceptible of improvement for that or any other purpose. In consequence we had to continue the development of the conduit system elsewhere—at Providence, at Allegheny City and finally at Boston, where it met its rival, the overhead trolley, and came to grief, not to revive again for ten years.

At the "Lab" Twenty-Five Years Ago.

By A. E. Winchester.

Good friend, receive the heartfelt and sincere congratulations of the humblest of the old-timers upon the attainment of your prime and hearty age of thirty years crowned with success, and the fact that you are looked forward to weekly with warm welcome wherever "currents" and "watt-berries" grow. May success abide permanently with you! Is it possible to give adequate expression to thoughts that flash through the mind of one trying to briefly review what science and electricity have wrought within the past quarter century? A history of untold volumes telling of man's great deeds of evolution and revolution. Did time and space permit, the task would be too great for me.

Looking from a window in the South Norwalk municipal electric works, I see a man in the distance; how slowly he walks, how small he looks. Viewed outwardly, how insignificant is man, after all. Divested of intellect, he is the most helpless of creatures. But endowed with reason, his physical weakness is not seen; he is master of all living things, and nature's forces respond to his touch. Electricity by his will has changed, within our memory, from a dreaded mystery to the most useful and familiar agent of our commercial and social existence. When, as a green run-away school-boy, I entered the budding Edison interests, every one connected with the meager science knew, or seemed to me to think they knew, all there was to know about the applications of electricity. It happened that I was soon assigned to do some work for Mr. Edison at the laboratory. I will never forget the sensation of awe that I felt as I stood gazing at the "old man," as he was called in endearment by his boys. He with characteristic unconsciousness worked away on his feeder-and-main scheme, without seeing me, until some one slapped him on the back and shouted in his ear, "Say, Tom, don't you see that chap wants to talk to you?" "Then why don't he talk?" was the ready reply, accompanied by a keen glance,—and after reading my credentials, a friendly smile. A grimy hand was shoved out to me. That was many years ago, but I will never get over being proud that a hand of mine shook the hand of Edison. Something about me, perhaps it was my modesty—I was still new to the business—reminded him of a story which had to be told before further operations could proceed. It was a good one, one of his "specials;" I remember it well, because others have since tried to work it off on me as original goods. Maybe I will whisper it as a familiar reminiscence of the "old man" sometime later, where the ventilation is good. When I left the laboratory that night, my hat fitted snug upon an expanding brow. I knew it all—all about filaments, lamp construction and the theory of sub-divided current. I thought I did, and was rather "chesty" to my less favored associates. However, the shrinking process came to my rescue in due time, and I have kept shrinking ever since, until now you can't find my little glim among the great lights of to-day.

But those early days brimmed full of exciting experiences, failures often and triumphs occasionally, but big ones when they came—lamps without life, others with too much, "shorts" that would not burn out, and armatures a-plenty that would, as the old boys can well remember. The bitter and the sweet of those times will never be tasted by those more recent in the field, because the days of the "rule of thumb," "cut and try" and "guess again" have passed out of operative electricity, and things are done right the first time now, because those old fellows of years ago found out how. The old-timers hewed their way up from the wilderness of obscurity to light, and left a broad path behind them reaching high up on Mount Progress to the zone of success for future generations to follow upward also, unhampered by doubts.

The Progress of Telegraphy During the Past Thirty Years.

BY WILLIAM MAVER, JR.

WHEN one regards the vast extent of the present-day applications of electricity, it is difficult to believe that thirty short years ago—less than the one-third of a century—the chief, indeed it may almost be said the only, important use of that force was in its application to electrical telegraphy. Yet such was the case. In the year 1874 the dynamo-electric machine, that revolutionizer—in fact, the creator—of many of the industrial arts of the greatest magnitude, was known, it is true, and the fact that it was reversible had already been discovered—a discovery that ranked as one of the most important of the nineteenth century. But its use was then very limited, and the crudity of the machine at that time is well exemplified by the manner in which the manufacturers of the period graded its capacity, namely, by saying, in all seriousness, it was equal to so many Bunsen cells; that it would take so many horse-power to drive it, or that it would heat a platinum wire of a certain length and thickness. The latter method of defining current strength, it may be noted, was also resorted to by the earlier experimenters as a means of designating the strength or capacity of Leyden jars. (*Query.*—Thirty years hence will some retrospective or reminiscent writer have occasion to note that the manufacturers of 1904, in all seriousness, defined the output of their generators of electromotive force as so many kilowatts, 90 per cent. efficiency, etc.?)

To show more clearly the progress of electrical telegraphy during the past thirty years, it may be advisable to refer briefly to the state of that art at that time or shortly prior thereto. Up to 1872 all overland wires, as well as the long submarine cables in this country and elsewhere, were worked single, as it is termed; that is, but one message was sent at a time over one wire. In this country the Morse manual telegraph system was, with the exception of the House and the Phelps printing telegraph systems, the only one in operation. The speed of transmission by the Morse manual method was from 20 to 40 words per minute, depending on the skill of the operator. The speed of the Phelps printer was about 50 words per minute. In Europe the systems most in vogue were various types of needle and dial telegraphs, together with the Hughes printer. The Atlantic cables were in operation, working at a speed of from 10 to 12 words per minute. In Great Britain the Wheatstone Automatic was working singly at the rate of 80 to 100 words per minute. Galvanized iron wires of No. 4, 6, 8 and 9 gauge, were used exclusively for overland purposes, and primary batteries, such as the Callaud or the Grove, were the only sources of e.m.f. employed on telegraph lines.

In 1872 a most important advance in the art of telegraphy was made in the application of the condenser to the Stearns duplex, which duplex had been introduced two or three years previously on the telegraph lines of this country. This invention by making it feasible to send two messages at once over one wire, doubled the capacity of all through overland wires on which it was applied; and it was not long thereafter before the duplex principle was successfully employed on the Atlantic and other long cables.

In the meantime Edison was assiduously working to perfect a quadruplex system of telegraphy by which four messages might be simultaneously transmitted over one wire, and in 1874 his efforts were rewarded with success. This achievement practically quadrupled the capacity of the through overland wires and thereby added thousands of miles to the existing facilities of the telegraph companies and governments employing it. It has been said by a recent imaginative writer that the quadruplex system sprang fully equipped in one night from the inventor's brain. The present writer has a clear recollection of rumor current at the time that the perfecting of the quadruplex was the result of many weeks and months of arduous toil, during many nights of which the inventor, when he slept at all, slept on the floor or on a bench beside the apparatus.

By the application of the duplex principle to the Atlantic cables the capacity of each cable has been doubled. This is likewise true of the land circuits on which the Wheatstone automatic system is employed. So that to-day, with other refinements in the art of submarine cable working, including the automatic transmission of messages, the capacity of an Atlantic cable is now about 22 words per minute in each direction. In Great Britain the capacity of a circuit employing the Wheatstone automatic system is now from 200 to 400 words per minute, depending on the length and other conditions of the circuit, in each direction.

During the past 30 years a number of rapid automatic telegraph systems have been tested in the United States, notably about 12 or 20 years ago, when more than one company was engaged in exploiting certain chemical and other automatic telegraph systems, to be operated at from 800 to 2,000 words per minute. But from various causes these systems were not permanently adopted, and the lines built for them were absorbed by companies operating on the manual Morse system. In Europe, within the past few years, several rapid automatic telegraph systems, capable, it is claimed, of transmitting messages at the rate of several thousand words per minute, have been tested; but it is not known that such systems have as yet gone into actual operation. The matter of rapid automatic telegraph transmission versus the Morse manual method, which later is practically the only one employed in America, Australia, New Zealand and largely in Europe and Great Britain, is a vexed question. There are those who consider that the retention of the Morse manual method is an evidence of backwardness on the part of those employing that system. But it should not be overlooked in this relation that the manual Morse method has of recent years gained ground in Great Britain and Europe generally, to do which it had to displace the one-time, almost generally employed, needle and dial systems. Furthermore, in Great Britain, where automatic telegraphy has been for many years in constant operation, and where, in fact, chemical automatic telegraphy had its birth, automatic telegraphy is to-day confined to the comparatively slow-speed Wheatstone system, which system is, it may be remarked, in great measure but a refinement of the Morse manual method of transmission.

On the continent of Europe the needle telegraph is still somewhat extensively employed. In France the Baudot synchronous printer, by which four messages are simultaneously transmitted over one wire, is now utilized on all the important through circuits, and affords a capacity of about 110 words per minute to each circuit. In this system, as well as in the case of the Hughes printer, which is also employed largely in Europe, the message is printed on a paper strip as received.

In this country the Buckingham printer, which operates at a speed of about 100 words per minute, in each direction, is employed on circuits from 500 to 1,000 miles in length. By this system messages are printed in page form on the ordinary telegraph blank as received. Two other important page-printing telegraph systems, namely, the Murray and Rowland, are now being experimented with in this country and Europe.

An important innovation in the method of preparing messages may be mentioned in the case of the Buckingham keyboard perforator, which was initially designed to prepare messages for transmission by this system, but which is now also used to prepare messages for transmission by the Wheatstone automatic system, employed on a number of circuits here, almost to the entire exclusion of the mallet method of preparing the messages. The keyboard method more than doubles the rate at which messages may be prepared for automatic transmission as compared with the mallet or hand-perforator. As an instance of this, it may be noted that one operator has perforated 850 messages in 11 consecutive hours by the keyboard perforator.

Among other developments of electrical telegraphy in the last 30 years has been the Delany synchronous system, which transmits four to six messages at once on one wire. This system has been employed in Great Britain for some years. The messages are transmitted manually at the ordinary rate. Another exceedingly valuable invention of recent years is that of Van Rysselberghe, by means of which it is possible to telegraph and telephone over the same wires at once; that is, while the two wires of the telephone circuit are being utilized for the transmission of speech on long-distance wires, both wires may at the same time be employed for ordinary telegraph purposes. In this country many telephone circuits are, by means of this system, operated also as telegraph wires. On the other hand, the telegraph wires of the country are used exclusively for telegraph purposes, but little effort having been made, it would seem, to utilize telephony as an adjunct to the regular business of telegraphy, which has long been an occasion of some wonder to the writer, although he is not unmindful of the difficulties of the matter. It should, however, be added in this relation that some of the telegraph wires of the railway companies of this country are utilized for simultaneous telegraphy and telephony. As long ago as 1890 the writer connected up the first set of apparatus for this purpose in the New York office of the telephone company for an experimental circuit between that city and Philadelphia.

As soon as the dynamo-electric machine was shown to be a practical source of e.m.f., it was quickly employed by the telegraph companies for that purpose, the first installation of which was made in the Western Union building in 1880. Since then primary batteries have been entirely dispensed with in all the large telegraph offices, dynamo machines or storage batteries replacing them. In 1884 the extensive employment of hard-drawn copper wire was begun by the telegraph companies, and its use has continued up to the present time, although large quantities of iron wire are still used in the telegraph service.

Still another obvious improvement in the telegraph service that has taken place in this country within the last decade is the general use of typewriters by the operators for the reception of business. This is not only more satisfactory to the public, but is a boon to the operators employing the typewriter, as it reduces the work of transcribing the messages to a minimum. Another recent improvement in this direction is the use of the typewriter keyboard as a transmitter of messages by the Morse alphabet; depression of a key effecting the transmission of dots and dashes corresponding to the letter represented by the key so depressed.

In one respect, however, it must be noted that within the last eight or ten years there has been a falling off in the efficiency of one branch of the telegraph service in this country, namely, that of the quadruplex system. This falling off in the efficiency is due to disturbances caused by the proximity of the wires of electric traction and other high-potential systems, and other causes, which appear to impair the operation of what is termed the "second" side of the Edison quadruplex system. Whether these causes of impaired efficiency will be overcome remains for the future to determine.

After all, the progress of electrical telegraphy in the past 30 years will perhaps best be shown by a comparison of the amount of wire then in operation for telegraph purposes, and by the number of messages then annually transmitted, with the mileage of telegraph wire now in use and the number of telegraph messages now transmitted annually. In 1874 there were perhaps not more than 150,000 miles of telegraph wire in this country; to-day there are over 1,000,000 miles of such wire in service, a large portion of which is either duplexed or quadruplexed. Thirty years ago not more than twelve or fifteen million telegraph messages were annually transmitted over the telegraph wires of the world. Now probably over 300,000,000 of messages of all classes are transmitted every year. This large volume of business is the more noticeable when the amazing growth of the telephone service is considered, and one is led to wonder what the extent of the telegraph service might have been had the telephone not appeared on the scene; for, while in many cases the telephone acts as a feeder for the telegraph, it is idle to pretend that the former does not in multitudes of instances take business that would otherwise have gone to the telegraph. In connection with the number of messages handled by telegraph, it may also be pointed out that within the last 15 or 20 years many of the largest users of the telegraph in this country have leased wires from the telegraph and telephone companies for private use, over which wires hundreds of thousands of messages are transmitted which do not appear in the public record as business transacted.

A record of the progress of telegraphy, however brief, could not, of course, be complete without reference to wireless telegraphy, the advent of which within the past five years has excited more popular interest than any means of transmitting intelligence to a distance that has been evolved within half a century. That art is now feeling its way and it will probably soon reach a substantial basis. Thus far many of the promises concerning its scope have not been fulfilled. It has hitherto fallen far short of providing transatlantic telegraphy, but its field of usefulness as a means of communication between vessels at sea and between vessels and the mainland is enlarging daily. Already it has demonstrated its value in many important instances, and with its increasing application to a larger number of vessels, to lighthouses, lightships, etc., its utility will be at least proportionately enhanced.

Fads in Engineering Practice.

By S. T. Dodd.

It is generally understood that engineering practice is dictated by engineering formulas, or practical commercial and financial considerations, and it might be supposed to be free from those waves of sentiment which often control masses of men in politics or religion, or which we call fads when we encounter them in the region of art and literature. It is very interesting to note, however, that the development of engineering practice is often accompanied by sudden revulsions which are not always guided by the best engineering considerations.

An instance of such revulsions is seen in the sudden demand during the last year for turbo-generators. Less than two years ago the discussion of a paper before the American Street Railway Association at Detroit, showed that there was a general timidity among operating men, as well as engineers, in regard to accepting the turbo-generator as a suitable unit for railway and power work. Engineers have not, up to the present time, had a very wide experience with turbines under fluctuating power loads, but the engineering profession in general seems to have gone to the other extreme in its acceptance of the turbine as a satisfactory and final form of prime-mover.

A representative of one of the large manufacturing concerns said to the writer the other day: "The country has gone turbo-crazy and hardly any consulting engineer dares to advocate reciprocating engines for fear he would be considered behind the times." While all the experience we have had up to date seems to indicate that the claims of advocates of the turbine are fairly borne out by practice, it hardly seems that this experience is sufficient to justify the sudden unanimous and overwhelming relegation of the reciprocating engine to the realm of out-of-date apparatus which the present tendency would seem to indicate.

Another fad which is based on still less valid considerations is the demand for increased sizes of cars on interurban electric roads. Ten years ago the first interurban cars on the Akron, Bedford & Cleveland Railroad weighed about 19 tons loaded, and had a seating capacity of 40 passengers. Since that time the technical press has been continually advocating the advisability of operating interurban roads along the lines of steam railroad practice, and some managers appear to have understood this as an advocacy of steam railroad cars for interurban railway service.

At any rate, we have noted, from time to time, in manufacturers' notices or descriptions of new roads, the increasing size of cars. The greed for greater seating capacity has increased the length of the cars to 45, 50 or even 60 ft. over all, the increase of weight of body necessary for rigidity, the introduction of hot-water heaters, air brakes, multiple-unit control, and the various paraphernalia of modern equipment has forced larger sizes of motors, greater weights of trucks and size of axles, and finally those of us who are conservatively inclined doubt very seriously whether, excepting in an advertising sense, the increased earning capacity of a 50-ton interurban car driven over tracks at 60 miles an hour with 500-hp of motors under it really justifies the increased first cost of the equipment, or the increased watt-hours per passenger carried, which are necessary to operate it under the conditions of grades and stops which we have to encounter.

It is refreshing occasionally to meet, as the writer did recently, a sane railway manager, who admits that his new interurbans are not proving the money-earners that he had expected; that his road has built up the resident population along his line; that with his increased stops he finds it pays him to reserve his new cars for limited and special runs, while he operates his old cars on the regular runs, and who says that when he is next in the market for equipments, he will go back to smaller cars and equipments with which he can make his frequent stops and keep his schedule without forcing the excessive fluctuations of loads on his power house and sub-stations which his new cars are demanding.

The writer believes that the modern demand for large size and excessive speeds of interurban electric cars is in the great majority of instances a fad which is not justified by considerations of economy or good engineering. One of the most annoying features of this development is the tendency of unscrupulous or ignorant promoters of new electric railway propositions to fill their prospectuses with specious arguments based on apparently accurate data of existing roads. Our reputable engineers are called on continually to combat such projects which show an earning power based on cars nearly equal in weight to Pullman sleepers running at speeds which are an engineering impossibility with any reasonable stops and grades, while the capacity of the equipment, the first cost and operating expenses are figured on the basis of existing roads operating cars of medium weights at reasonable speeds and giving satisfactory service to the territory they serve.

To-day we are confronted by the promise of a new fad. Any one who is familiar with the electric railway situation in the Middle West cannot fail to be impressed that the widespread interest which has been excited by the alternating-current motor. Speculation is rife among engineers as to whether we have not arrived with it at the solution of voltage limitations and distribution troubles incidental to our present practice on suburban and even on city lines. It is seriously questioned whether it would not pay to scrap existing apparatus and replace it with alternating-current railway equipment. The writer does not wish to be understood as saying that there is not a great field for the alternating-current, single-phase railway motor, or that the field which it will open will not be one that is as yet practically untouched by electric railway apparatus; but he does seriously question whether, except in special instances, existing electric roads could be advantageously improved in economy by the substitution of alternating-current equipments for their present apparatus. Electrical apparatus, like the rest of mankind, "is of a few days and full of trouble," and whether the maintenance and operating expense of alternating equipments will be less than direct-current equipments can only be decided by extensive experiments.

In the meanwhile, the time is now ripe for a careful conservative discussion of the engineering, commercial and financial questions bearing on the advantages and disadvantages of alternating-current railway equipments on interurban roads running over highway or private right-of-way, as we know them to-day. As the writer sees the situation, such a discussion at the present time and a clear understanding of the principles involved would save in the near future a considerable investment in costly experimentation on some propositions, the result of which, on general principles, might have been expected beforehand.

Expansion and Changes of Electric Light and Power Systems.

By ALTON D. ADAMS.

EXPANSION of electric systems has been accompanied by constant changes in the character and relation of station equipments and the connected loads. Perhaps none of these changes have been more notable than those in the relations of connected loads to station capacities and operation. During the first decade of electric lighting from public systems the combined capacity of street lamps and commercial lamps and motors was generally less than the capacity of the generating apparatus in stations to which they were connected. This condition continued up to about 1890, but since that year the lamps and motors supplied with energy from public electric systems have shown an almost constantly increasing excess of capacity over that of the generating stations to which they are connected. An illustration of this fact is found in the figures for total generating and connected capacities in the electric lighting systems of Massachusetts in each year, from 1888 to 1900. On June 30, 1888, the total capacity of dynamos in all the electric lighting stations of Massachusetts was 6,842 kw, and on the same date the lamps and electric motors of all sorts connected to these stations had a combined capacity of 6,117 kw. Twelve years later, on June 30, 1900, the generating capacity of the stations had increased to 68,941 kw, or to 10 times the like capacity for the earlier year.

During the same period the combined capacity of lamps and motors supplied from these stations rose to 96,650 kw, or 15.8 times the connected capacity in 1888. The total capacity of connected apparatus was 89.40 per cent. of the station capacity in 1888, but every subsequent year showed an increase of this per cent. and it stood at 140.19 in 1900. In 1888 the maximum load of electrical supply stations might well be the entire connected load of the systems, and as a matter of fact this was often substantially the case. In 1900 a little more than two-thirds of the capacity in lamps and motors connected to the systems was sufficient to tax the generating equipments to their full rating. For example, see the following table:

Kilowatt capacities of dynamos and connected loads of lamps and motors for electrical supply stations in Massachusetts:

Year of June 30.	Dynamo capacities.	Capacities of lamps and motors.	Per cent. of lamp and motor to dynamo capacities.
1888	6,842	6,117	89.40
1889	10,074	9,599	95.28
1890	15,244	14,458	94.84
1891	18,593	20,441	109.93
1892	21,188	25,701	121.30
1893	26,953	30,178	111.96
1894	31,749	38,522	121.33
1895	33,256	44,592	134.00
1896	40,226	54,850	136.35
1897	45,461	64,501	141.88
1898	50,490	73,028	144.63
1899	63,020	83,943	133.20
1900	68,941	96,650	140.19

The great increase of capacity in connected loads compared with dynamo capacities has been made possible mainly by three important factors. These are storage batteries, residence lighting and motor loads. Storage batteries have operated directly to cut down the required capacities of dynamos by carrying a considerable portion of the maximum load. The ultimate effect of storage batteries has obviously been to lengthen the hours of daily and yearly operation for generating apparatus. What storage batteries have done indirectly, residence lighting and motor loads have done directly by demands for energy at times of day when street and business lighting was not required. The increase of average electrical loads since 1888 has probably not been as rapid as the rise of connected loads. This conclusion follows because lamps in residences are in use a smaller average number of hours daily than lamps in business houses, and from the fact that electric motors, though often operated more hours per day than lamps, often run on loads much below their rated capacities. Maximum loads find their limits not in connected lamps and motors, during recent years, but in the capacities of station dynamos and storage batteries. In 1888 the capacity of all connected lamps and motors was less by 10 per cent. than that of the station dynamos by which they were supplied. In 1900 these lamps and motors had a capacity 40 per cent. greater than that of station dynamos.

Storage batteries had not begun to play their part in electrical supply to any considerable extent in 1888, and dynamos alone represented the entire capacity of stations. To have given electric stations capacities the same relation to connected loads in 1900 that they had in 1888, these capacities must have stood at 108,109 kw in the later year. This could have been done with storage batteries capable of discharging during a period of two to three hours at the rate of 39,168 kw, but the capacity of the batteries actually in use seems to have been much below these figures. Though the increase of average loads has fallen behind that of connected loads, it may well have exceeded the rise of maximum loads as indicated by battery and dynamo capacities.

Within electric stations changes have been going on not less marked than the relation of dynamo capacities to outside loads. From 1888 to 1894 the number of engines in the stations of electric lighting systems rose with the sum of their capacities, though not at so rapid a rate. This was the era of comparatively small high-speed engines, each belted to one or two dynamos. During these six years the number of engines rose from 149 to 347, or to 2.3 times that of the former year. Meantime engine capacities went up from 11,515 to 54,729 hp, or 4.7 times the earlier capacity. At the beginning of this period the average rating of each engine was 77 hp, and in 1894 this rating stood at 157 hp. In other words, not only the number of engines, but also their average horse-power more than doubled between 1888 and 1894. Beginning with 1895 a marked change in the engine situation set in. In this year the number of engines showed a decline for the first time during the entire period, though there was a small increase of capacity. This effect was probably due in large part to the introduction of comparatively large engines direct-connected to their dynamos. In 1895 the number of engines in electric lighting stations throughout the State was 319, and stood at 343 in 1900, having touched its highest point, of 352, in 1899. Meantime, the total horse-power of these engines went up from 55,548 in the earlier to 80,115 in the latter year. This increase of engine capacity carried the average horse-power per engine up from 174 in 1895, to 248 in 1900. During the twelve years between 1888 and 1900 the number of engines was multiplied by 2.3, the average horse-power by 3.2, and the total horse-power by nearly 7. Dynamos in electric lighting stations began to decline as to numbers after 1893 and again after 1897, having gained nearly 50 per cent. between these years. In 1897 the figures for dynamos had advanced to 975 from 348, in 1888, but by 1900 this maximum had fallen to 827. Total dynamo capacities exhibit an unbroken advance from 1888 to 1900, and this is also true of average capacities, except for the years of 1896 and 1897.

Numbers and capacities of engines in private electric lighting stations of Massachusetts:

Year of June 30.	Number of engines.	Total horse-power of engines.	Average horse-power of engines.
1888	140	11,515	77.3
1889	199	18,752	94.2
1890	254	27,199	107.0
1891	280	34,453	123.0
1892	309	41,499	134.3
1893	333	50,739	152.3
1894	347	54,729	157.7
1895	319	55,548	174.1
1896	325	60,868	187.1
1897	340	64,527	189.8
1898	348	66,468	191.0
1899	352	77,439	219.9
1900	343	80,115	248.1

From 1888 to 1900 the number of dynamos grew from 348 to 827, or to 2.4 times the former figure. Meantime, average dynamo capacity was multiplied 4.3 times, and total capacity of dynamos in lighting stations ten times. As in the case of engines, the reduction in the total number of dynamos, in spite of rapidly rising combined capacity, was largely due to the substitution of direct-connected for smaller belted units. In dynamos and engines now used to carry much the greater part of lighting and stationary motor loads, the reduction of numbers has been much greater, and the increase of average capacities more marked than the table indicates. This fact results from a practice by which, when large direct-connected units are installed, the smaller engines and dynamos formerly used are retained for occasional service.

Numbers and capacities of dynamos in private electric lighting stations:

Year of June 30.	Number of dynamos.	Total kilowatts of dynamos.	Average kilowatts of dynamos.
1888	348	6,842	19.6
1889	458	10,074	22.0
1890	635	15,244	24.0
1891	647	18,593	28.7
1892	723	21,188	29.3
1893	846	26,953	31.8
1894	659	31,749	48.2
1895	669	33,256	49.7
1896	816	40,226	49.3
1897	975	45,461	46.6
1898	892	50,490	56.6
1899	889	63,020	70.9
1900	827	68,941	83.3

An extreme illustration of this point may be noted in the case of the Boston Edison Company. For the year of 1900 this company had in its stations 38 engines and 76 dynamos. As a matter of operation, however, all except a very small part of the energy output of the company during that year was developed at one of its stations by 7 engines and 12 direct-connected dynamos. Two marked changes took place between 1888 and 1900 in the ratio of total dynamo to total engine capacities. To bring out these changes the kilowatts of total dynamo capacity in each year are reduced to horse-power by division with the factor 0.746. Comparing the horse-power capacities of engines and dynamos for the year of 1888, it seems that the latter was only 79.6 per cent. of the former.

The ratio of dynamo to engine capacity fell from the figure just named to 68.4 per cent., in 1892; from this point it rapidly rose to 115.3 per cent. in 1900. These changes have, no doubt, had an important influence on the efficiencies of electric stations. At best, dynamos must operate during quite a portion of their running time on much less than full loads, and this is especially true when few, if any, storage batteries are in use as was the case in 1888 to 1892. If dynamos at full load require only 68.4 per cent. of the rated capacities of their engines, these dynamos on their actual average loads probably require much less than one-half of the power than engines can deliver when working at their points of highest efficiency.

A result of these conditions can hardly fail to be a low efficiency of operation. The marked rise in the ratio of dynamo to engine capacities since 1892 has been mainly due to two causes: the extended use of water power with electric stations, and a better proportion of dynamo to engine ratings. Since the year just named, the proportion of dynamo to engine ratings has increased by $(115.3 - 68.4) \div 68.4 = 68$ per cent. While a part of this increase has been due to the extended application of water power, it seems that a still larger part is the result of better proportions between engines and their driven dynamos. It might be expected that the gradual substitution of large direct-connected units for belt-driven dynamos would work a reduction in the ratio of dynamo to engine numbers.

Ratio of dynamo numbers and capacity to engine numbers and capacity:

Year of June 30.	Horse-power of all dynamos.	Per cent. of dynamos to engine capacity.	Average number dynamos to each engine.
1888	9,171	79.6	2.3
1889	13,504	72.0	2.3
1890	20,434	75.1	2.5
1891	24,923	72.3	2.3
1892	28,402	68.4	2.3
1893	36,130	71.1	2.5
1894	42,558	77.7	1.9
1895	44,579	80.2	2.1
1896	53,922	88.5	2.5
1897	60,403	93.6	2.8
1898	67,680	101.8	2.5
1899	84,477	109.0	2.5
1900	92,414	115.3	2.4

The retention of old machines, however, has held the ratio of dynamos to engines between 1.9 and 2.8.

Changes in the relative capacities of arc lamps, incandescent lamps and motors that went to make up the total connected loads have been second in importance only to the combined increase of these loads. In 1888 the capacity of loads connected to electric lighting stations was 2,631 kw for arc lamps, 2,872 kw for incandescent lamps, and 614 kw for motors. Arc lamps thus represented 43 per cent., incandescent lamps 46.9 per cent., and motors 10 per cent. of the total connected capacity. In marked contrast with these figures, the total connected load for 1900 was made up as to capacity of 9.6 per cent. in arc lamps, 62.2 per cent. in incandescent lamps, and 28 per cent. in motors.

Kilowatts of connected lamps and motors in each year:

Year of June 30.	Total for arc lamps.	Total for incandescent lamps.	Total for motors.
1888	2631	2,871	614
1889	3530	4,646	1,422
1890	3999	7,735	2,723
1891	4747	10,443	5,250
1892	5638	14,577	5,485
1893	6233	17,097	6,848
1894	6640	22,937	8,944
1895	6925	26,742	10,924
1896	7485	33,435	13,930
1897	7811	40,371	16,318
1898	7938	46,159	18,930
1899	8501	52,702	22,740
1900	9342	60,175	27,133

During the twelve years in question, the total connected load grew to 15.6 times, the arc load to 3.5 times, the incandescent load to 20.9 times and the motor load to 44.1 times that at the beginning. For the year of 1900 arc lamps represented only 0.22 times, while incandescent lamps had 1.3 times and motors 2.8 times their per cent. of total connected capacity in 1888. Between 1888 and 1900 arc lamps lost 33.4 per cent. of connected load capacity. Of this loss, incandescent lamps gained 15.3 per cent. and motors 18 per cent. of the total connected capacity. Arc lamps show an uninterrupted decline in their share of the total load capacity during the entire period. Incandescent lamp capacities either gained or held their own up to 1898, except for the year of 1891.

Per cent. of total load capacity in arc lamps, incandescent lamps and motors for each year:

Year of June 30.	Per cent. in motors.	Per cent. in arc lamps.	Per cent. incandescent lamps.
1888	10.0	43.0	46.9
1889	14.8	36.7	48.4
1890	18.8	27.6	53.5
1891	25.6	23.2	51.0
1892	21.3	21.9	56.7
1893	22.6	20.6	56.6
1894	23.2	17.2	59.5
1895	24.4	15.5	59.9
1896	25.3	13.6	60.9
1897	25.2	12.1	62.5
1898	25.0	10.8	63.2
1899	27.0	10.1	62.7
1900	28.0	9.6	62.2

Since 1898 incandescent lamps have lost 1 per cent. in their ratio to total connected capacity. In contrast with arc lamps, electric motors show a continuous rise in their per cent. of total connected capacity for every year, save 1892 and 1897. During the four years between 1888 and 1892 the ratio of arc lamps to total load capacity was reduced one-half, the like ratio for electric motors more than doubled, and incandescent lamps gained 10 per cent. on total capacity. In 1888 the capacity of connected incandescent lamps was a little greater than that of arcs, and nearly five times the capacity of motors. In 1900 arc lamps supplied less than one-sixth, and motors a little under one-half as much of the connected load as incandescent lamps.

In 1894 the capacity of incandescent lamps and motors connected to electric stations was 31,881 kw. while the total dynamo capacity was 31,749, so the connected load exceeded the generating capacity at stations by more than the 6,640 kw of arc lamps. By the middle of 1895 the connected load exceeded the dynamo capacity by more than the kilowatts of connected motors. For all except one of the five following years the sum of capacities of arc and incandescent lamps has been greater than the dynamo capacity. In 1900 the excess of connected loads over dynamo capacities was 27,709 kw. The existence of these facts brings out strongly the tendency during the decade to broaden out the loads of electrical systems over a larger part of each day.

Differences of kilowatt capacities of connected lamps and motors and the capacities of dynamos at electric stations:

Year of June 30.	Kilowatts excess of connected load.	Kilowatts excess of dynamos.
1888	......	725
1889	......	475
1890	......	786
1891	1,848	...
1892	4,513	...
1893	3,225	...
1894	6,773	...
1895	11,336	...
1896	14,624	...
1897	19,040	...
1898	22,538	...
1899	20,923	...
1900	27,709	...

That there was great expansion in the amount of electrical service during the period under consideration is certain; but it is no easy matter to determine just how much the sales of electrical energy went up. Measured by total energy income, electrical service increased from a value of $1,908,394 in 1890 to $5,622,556.43 in 1900, or to 2.94 times the former amount. This increase of income, however, cannot be taken as a true measure of the rise in amount of electrical energy supplied, because, as has been shown elsewhere, there was a consiedrable decline of prices during the decade. If, on the other hand, the kilowatts of connected capacity in lamps and motors are taken as a direct measure of the energy supplied in each year, the result will be in error, because the yearly output of energy per unit of connected capacity in lamps and motors has declined during the period. Since prices for electrical energy have declined, the increase of energy sold must be greater than the increase of energy income. It follows that the sales of energy in 1900 were more than 2.94 times the like sales in 1890. The kilowatt capacity of all connected lamps and motors was 6.68 times as great in 1900 as in 1890, but the ratio of energy outputs must have been somewhat less than this number for these two years. It thus seems clear that the kilowatt-hours sold by electric lighting systems were somewhere between 2.94 times and 6.68 times as great in 1900 as they were in 1890. With constant prices per kilowatt-hour, the income per kilowatt capacity of connected lamps and motors would vary directly with the number of hours of yearly service for each connected unit at its full capacity. As prices have, in fact, been falling, the hours of yearly service for each unit of connected capacity have not decreased as fast as the income per unit of this capacity. In 1890 the energy income of electrical systems was $131.99 per unit of capacity in connected lamps and motors, but for 1900 this income fell to $58.17, or 0.44 of the like income in the former year. From this it appears that the average yearly hours of service for each kilowatt of connected capacity were more than 0.44 times as great in 1900 as in 1890.

Income from sales of electrical energy per kilowatt of capacity in connected lamps and motors:

Year of June 30.	Total energy income.	Income per kilowatt capacity.
1890	$1,908,394.00	$131.99
1891	2,432,869.15	119.01
1892	2,947,199.64	114.65
1893	3,427,576.84	113.59
1894	3,693,056.92	95.86
1895	3,794,060.41	85.08
1896	4,148,681.71	75.63
1897	4,467,146.60	69.25
1898	4,775,316.07	65.39
1899	5,046,412.75	60.11
1900	5,622,556.43	58.17

Energy income per kilowatt capacity of arc lamps, of incandescent lamps and of motors, connected to electrical supply systems:

Year of June 30.	Income for arc lamps.	Income for incandescent lamps.	Income for motors.
1896	$226.15	$57.98	$37.13
1897	224.66	52.54	36.20
1898	228.30	50.39	33.64
1899	212.68	47.64	31.98
1900	199.90	48.46	30.90

Arc lamps, incandescent lamps and motors show widely different yearly incomes per kilowatt of their connected capacities. In 1896 the $226.15 received for each kilowatt of capacity in arc lamps was 3.9 times the $57.98 received per like capacity in incandescent lamps, and 6.1 times the $37.13 received for each kilowatt of connected motors.

For the year of 1900, when one kilowatt of capacity in arc lamps earned $199.90, the same capacity in connected incandescent lamps earned $48.46, or 28.2 per cent. of the amount received from arcs, while one kilowatt of connected motor capacity brought an average income of only $30.90, or 15.4 per cent. of the income from the same capacity in arcs. The high rate of earning capacity shown for arc lamps is, no doubt, due in part to higher prices for this than for the other classes of service. A more important reason for the higher income per unit of capacity in arcs exists in their longer hours of average yearly service, compared with incandescent lamps and motors. It should be noted that arc and incandescent lamps usually operate at about full capacity when in service, while for motors this is not true. Motors usually operate more hours daily than do incandescent lamps, but during much of the time carry only fractions of their rated loads. It seems probable, however, that the hours of service for motors, reduced to terms of full rated load, would probably be as great in number as the hours for incandescent lamps. To compute the capacities of the electric lamps here considered, 60 watts are allowed for each commercial incandescent lamp, 90 watts for each incandescent street lamp and 400 watts for each arc lamp of any sort, in every year. It is believed that these factors are sufficiently near the truth to warrant the foregoing conclusions as to kilowatts of capacity in connected loads.

Thirty Years of Telegraphy and Allied Arts.

By Francis W. Jones.

The achievements of brains, capital and labor in the domain of electricity, to which subject this journal has been devoted for thirty years, would be impossible to review even as a condensed summary in a single special number of it, unless it were unduly enlarged to the proportions of a library. Such a complete review, however, is unnecessary, as the Electrical World and Engineer during this period is accessible, and its records of passing events have been very full and accurate. These records have had much more than a passive value: they have been continuously most potent aids and stimulants to its readers who were employed in the application of electricity to some useful purpose, and invaluable to teachers engaged in imparting correct information to pupils. It is only by comparison that an idea is formed of dimensions, and no doubt its review will bring into bold relief the astounding developments of the thirty pregnant years during which it has been our good fortune to live.

At the time this journal started, electricity was only utilized for telegraphy, fire alarm systems and for house bells. True, that up to 1874, sporadic attempts had been made to establish an electric light, dating back to Volta's great invention of the Voltaic battery, notably by Deleuil and Archereau in 1841, Dubosq, 1846, Staite, 1847, Cassagnes and Thiers, 1855, and last, but no least, Gramme in 1870: but at that time it had not doffed its swaddling clothes. The Electrical World and Engineer has had the privilege to record many notable inventions.

In 1874 there had been laid, in various countries, 215 cables of a total of 47,000 miles. Many were unworkable. Now there are 266,153 statute miles of working deep-sea cables, and the speed of transmission which, in 1874 was about 15 words per minute through an Atlantic cable, has now reached 47.4 words per minute over the Anglo 1894 cable 2,132 miles long, and 40 words per minute over the Commercial's 1894 cable 2,491 miles long. These number of words per minute have been more than doubled by use of the duplex upon each of the cables named: the duplex (which was introduced since 1874) being able to more than double the speed, because no switches have to be turned nor keys opened, and the readable character of the signals greatly improved by the employment of automatic transmission.

In this country, the growth of the telegraph during thirty years cannot be accurately stated. The Western Union Telegraph Company in 1874 had 175,735 miles of land wires, in addition to which were a few thousand miles of wires owned by railroads and small competing companies. In 1904 there are over 1,400,000 miles of aerial wires, not including railroads, devoted to commercial use in the United States.

In 1877 the telephone began its development, which has been phenomenal, and it has practically supplanted the telegraph in all urban communication, besides creating a tremendous business of its own, both urban and interurban, peculiar to its extreme simplicity and absence of skill in operation.

Notwithstanding the introduction of the telephone into the field of telegraphy in 1877 in this country, the mileage of telegraph wires has grown 1,200,000 miles, with an increase in ordinary telegrams of about 50 millions. Great improvement has been effected in the character and stability of poles, fixtures and wires, until now the cutting off of the principal commercial cities from each other by storms is rarely experienced, whereas, thirty years ago, it was a frequent occurrence for the telegraph company to forward large packages of delayed telegrams by train to points beyond the breaks caused by winds and sleets.

The development of Edison's quadruplex system, which is largely used, Baudot's and Delany's multiplex synchronous systems for land wires, are notable matters of record. These systems afford the present maximum traffic possibilities over a single wire, unless we except the older automatic system of Wheatstone, which has only a limited use both here and abroad. Gradual and important improvements have been made in all classes of apparatus, in wiring and switching systems.

No imagination can picture what this journal will record in 1924, on the occasion of its semi-centennial celebration or jubilee.

I have not alluded to the birth of the Edison phonograph, the first public exhibition of which I had the honor to make at 455 Madison Street, Chicago, from July 3 to 9, 1878, and then in the other largest Illinois cities; nor of the Edison incandescent lamp and the wonderful system of distribution developed at Menlo Park in 1879 and the early part of 1880. I had the honor also of being the expert employed by the syndicate of capitalists behind Edison in the early fall of 1880, to advise them if the lamp, with the carbonized cotton filament, would probably warrant them putting up money to go into competition with gas. Although my humble advice was favorable, I confess I had no dream that within twenty-four years the lamps would outnumber the stars over the entire civilized globe. Not even such a thing was foreshadowed in the then current numbers of this journal.

The Diversity of Electrical Development.

By Schuyler Skaats Wheeler.

It is not possible, in my opinion, to point out any one event of special separate importance connected with the electrical developments during the last thirty years, which is the period covered by the existence of your journal, inasmuch as so many wonderful things have been accomplished. In fact, the lifetime of your paper covers the entire electrical era.

I believe that electricity's wonderful industrial advance is particularly due to the invention and development of many different things, which though entirely dissimilar, have co-operated remarkably in stimulating the use each of the other.

The incandescent lamp, the dynamo, the constant potential system, the motor, the telephone, the telegraph, electric traction, wireless telegraphy, the turbine, the remodeling of all kinds of machinery for the use of the motor—who can say which of these has been the most important? I believe that each one has been important and that all of the others have been promoted by its success. By its drawing the public attention to the facilities of electricity, all of the others have been promoted by its success. In other words, I think that the field of electrical industries is remarkable for the extent to which inventions and successes that have nothing to do with other inventions have helped the latter by adding to the advancement of the entire field.

Our industry has one peculiarity which I think is interesting, namely, the remarkable extent to which the layman feels compelled to hold aloof from active participation in its practical work, believing that he is incapable of coping with so mysterious a subject. The fact that the industry as a whole has now become one of the leading departments of human endeavor, being one in which immense capital and millions of people are employed, makes it general and not a limited specialty, and yet all outsiders and many of those actually employed by it, feel that they can have very little to do with the practical part, a condition which I believe does not exist in any other line of work that has reached similar magnitude. On a pinch anybody will repair a steam or gas pipe. Who will repair an electric wire?

The Place of the Storage Battery in the Art.

By Charles Blizard.

In response to your kind intimation, I beg to express the opinion that the improvements embodied in the storage battery of to-day—most largely responsible for the conspicuous position it fills in the electrical field, are those which enable it to successfully withstand the high rates of discharge and to give satisfactory life and service in the hands of attendants who are not battery experts.

Without the ability to meet sudden excessive demands for power, the storage battery could not fill the requirements of several classes of application in which it is now prominent; and it would also lose much of its value as a reserve. If it could be successfully operated only by those who had especially fitted themselves for its care, its field would be comparatively limited.

Not until the storage battery had fully demonstrated that it possessed these essentials to success did its use become general. The lack of these qualities was the heaviest handicap on the storage battery of fifteen years ago.

Improvements recently made in the storage battery will further increase its life and reduce the amount of attention required.

A Review of Twenty-Five Years of Telephony.

By ARTHUR VAUGHAN ABBOTT, C. E.

THE latter part of the nineteenth century, and the first quarter of the twentieth, may be called the "Age of Transportation," because during this period greater changes in the arts of intercommunication have occurred than during any previous epoch. These improvements have been accomplished by the aid of electricity, and this agent is further responsible for a completely new method of intercommunication which has already revolutionized modern business, and bids fair to be even a more potent factor in the future. This is the art of *selling conversational facilities* or *telephony*. The ELECTRICAL WORLD AND ENGINEER was about two and a half years old when at the Centennial Exposition of 1876, the telephone was "born." In the beginning it was regarded as a mere mechanical toy, curious perhaps, but of no practical value. To-day, in the United States, there are over three million telephone subscribers, whose daily conversations, over the wire, aggregate twenty millions, while the world numbers twice as many more. In the business of "conversation traffic" hundreds of millions are invested, tens of thousands of employees daily engaged, and thousands of companies find their sole occupation.

Like other enterprises having a scientific basis, there have been two phases of development—the engineering aspect, and the commercial one. From the engineer's standpoint the invention of the magneto telephone formed the keystone upon which all subsequent development rested, and while too much cannot be said of the genius of Professor Graham Bell in solving the problem of the electrical transmission of speech, many other inventions were necessary to render the telephonic systems of to-day possibilities. While the magneto proved itself so efficient a receiver that the original model survives, it failed as a transmitter, and the second step was the invention of the carbon battery transmitter of Edison and others. In this electricians broke away from the idea of utilizing the feeble energy of vocal sound waves as the source of power, and supplied

The Telephone.

THE proprietors of the Telephone, the invention of Alexander Graham Bell, for which patents have been issued by the United States and Great Britain, are now prepared to furnish Telephones for the transmission of articulate speech through instruments not more than twenty miles apart. Conversation can be easily carried on after slight practice and with the occasional repetition of a word or sentence. On first listening to the Telephone, though the sound is perfectly audible, the articulation seems to be indistinct; but after a few trials the ear becomes accustomed to the peculiar sound and finds little difficulty in understanding the words.

The Telephone should be set in a quiet place, where there is no noise which would interrupt ordinary conversation.

The advantages of the Telephone over the Telegraph for local business are

1st. That no skilled operator is required, but direct communication may be had by speech without the intervention of a third person.

2d. That the communication is much more rapid, the average number of words transmitted a minute by Morse Sounder being from fifteen to twenty, by Telephone from one to two hundred.

3d. That no expense is required either for its operation, maintenance, or repair. It needs no battery, and has no complicated machinery. It is unsurpassed for economy and simplicity.

The Terms for leasing two Telephones for social purposes connecting a dwelling-house with any other building will be $20 a year, for business purposes $40 a year, payable semiannually in advance, with the cost of expressage from Boston, New York, Cincinnati, Chicago, St Louis, or San Francisco. The instruments will be kept in good working order by the lessors, free of expense, except from injuries resulting from great carelessness.

Several Telephones can be placed on the same line at an additional rental of $10 for each instrument, but the use of more than two on the same line where privacy is required is not advised. Any person within ordinary hearing distance can hear the voice calling through the Telephone. If a louder call is required one can be furnished for $5.

Telegraph lines will be constructed by the proprietors if desired. The price will vary from $100 to $150 a mile; any good mechanic can construct a line; No. 9 wire costs 8½ cents a pound, 320 pounds to the mile; 34 insulators at 25 cents each; the price of poles and setting varies in every locality; stringing wire $5 per mile; sundries $10 per mile.

Parties leasing the Telephones incur no expense beyond the annual rental and the repair of the line wire. On the following pages are extracts from the Press and other sources relating to the Telephone.

GARDINER G. HUBBARD.

CAMBRIDGE, MASS., May, 1877.

THOS. A. WATSON, 109 COURT ST., BOSTON.

FIRST CIRCULAR EVER ISSUED FOR TELEPHONE BUSINESS.
(Reduced Fac Simile of Original in Possession of T. C. Martin.)

the transmitter with a battery, capable of furnishing energy, employing the sound waves simply to actuate a releasing mechanism to regulate the battery discharge. The use of a battery necessitated some means whereby its circuit could be closed and opened whenever the telephone was placed in, or out of service. To rely upon a manual switch, dependent on the fallible memory of the subscriber, was impractical and the invention of the *"hook switch"* made the commercial use of the battery transmitter possible.

The next problem was a sub-station signal, for at best the voice of the receiver was too feeble to attract attention. Batteries and vibrating bells gave no end of bother, but the *"magneto bell"* and *"hand generator"* have proved so satisfactory a solution that no one proposes a better. Growing demand showed electricians that the time was at hand when the lines of many users must be concentrated at a single point. How to quickly and surely interconnect various wires became the next question, which was answered by the invention of the *"spring jack."* From time to time improvements in methods of jack manufacture, or economy of space, have arisen, but the jack as a piece of apparatus has survived unchanged, nor does it seem that the near future will offer any substitute.

Soon it became impractical to place before a single attendant a sufficient number of jacks to care for all lines of even a small territory, so section after section of switchboard was required. To connect the wires in one with those of another, local circuits were devised, but this rendered operating slow and cumbersome. The invention of the *"multiple switchboard,"* whereby the line of every subscriber is carried through a multiplicity of jacks so that each attendant can reach the line of every one, marked a vital advance.

For the first decade, the wire plant consisted solely of aerial grounded lines of iron wire, but its objectionable magnetic characteristics, together with rapidly increasing introduction of other electrical industries made it imperative to improve the conducting system. First came the invention *"hard drawn copper wire,"* rendering it possible to build open wire lines of much better conductivity, having no objectionable magnetic characteristics; and the substitution of the complete *"metallic circuit"* removed inductive difficulties. Then came the *"paper cable"* into whose leaden embrace two or three hundred circuits can be packed in a space of four or five square inches, and as a sequence the *"underground conduit."*

To economize installation expense several stations were connected to a single line, but transmission limits were soon reached, as it was impossible to talk through the impedance of the bell magnets. The *"bridging bell"* wound to give too great an impedance to sensibly divert the high frequencies of voice currents, enabled ringers to be placed as shunts and made the *"party line"* a success.

For many years, at the central office, the old-fashioned drop reigned supreme as the subscriber's signal, but presently the demand for quicker service required a means more salient, and completely automatic, and the *"incandescent lamp"* and *"bridging board"* replaced the old series multiple. The local battery presented a stupendous problem. In Greater New York upwards of a hundred thousands stations exist. Consider the task of making eight hundred thousand or a million battery renewals per annum in one city. The solution was the *"common battery"* system, whereby each central office supplies electricity for all subscribers.

With the growth of the art came the demand to talk over greater distances. Boston must speak to Chicago and San Francisco; New York desires to talk with London, but the electrical characteristics of even the most heavily coppered aerial lines place the barrier to commercial transmission at about 1,000 miles of open wire, while but a fraction of this distance through submarine cable is practical. To the electrical engineer there is no such word as "fail," and the *"loaded line"* in which objectionable inductance is made to counterbalance and neutralize equally destructive capacity, has produced a circuit whereby even trans-oceanic telephony seems within grasp.

Turning from the engineering to the business aspect, the sagacity which has constructed the present telephone system is equally wonderful. The fundamental patents of the magneto telephone were secured by the original Bell Telephone Company, which through various organizational permutations and combinations has been known successively as the American Bell Telephone Company and the American Telephone and Telegraph Company. The original policy was to control the manufacture of telephonic apparatus, and to rent the same to those who desired to use it. So the parent company succeeded in building up in nearly all our cities and in many European ones, operating corporations whose business it was to *sell service*. As to the policy pursued there may be many, and very honest differences of opinion; to err is human. It would be impossible to expect such an organization to conduct for a quarter of a century its business to the liking of every one, but, however, much one may disagree with many of the methods adopted, no one can fail to admire the skill and tact which conceived and executed the plan that successfully welded together hundreds of diverse organizations.

It was natural at the outset to adopt the plan of renting telephonic instruments, and if the early idea of only leasing them had been adhered to, allowing those who obtain them to serve themselves, the flat rate charge would be legitimate. But telephone companies became operators. They not only manufactured apparatus but furnished service, so now the supply of apparatus is but a small portion of the real business. What the telephone company offers is the transportation of intelligence. To charge each subscriber $50 per year for a telephone is as absurd as for a railway company to charge each of its freight customers $1,000 per year for a locomotive. One of the most significant steps in telephonic policy is the adoption of "measured service," whereby the subscriber is billed at a certain rate for every message transmitted. To-day the unit of charge is the call. That this is more equitable than any flat rate system is obvious, but it is equally plain that the call is not a true unit. It is unfair to charge a man who talks ten minutes the same price as one who talks one. It is equally unfair to charge one customer the same rate for a message transmitted one mile as is made to another who talks ten miles. Toll service early recognized this fallacy and toll charges are based both upon mileage and time. While to adopt a similar system for ordinary city exchanges may tax the ingenuity of the auditor, it is a reform which sooner or later will appear.

Half a dozen years ago the fundamental patents expired, and the field became open to all. Stimulated by the success of telephony, hosts of inventors and investors hastened to avail themselves of the opportunity. Naturally all who had from time to time disagreed with the policy of the older company arrayed themselves upon the other side; some thousands of "Independent" organizations have appeared, and several hundred "Independent" manufacturers of apparatus are at work. Within a decade the number of telephonic subscribers have been quintupled, of which the "Independents" claim about half.

What of the future? First and foremost is the certainty that the enormous growth of the past will continue, though probably at a decreasing rate. In the United States there are upwards of twenty million families, and at least five million places of business, making a total of twenty-five million opportunities to install telephones. Of these about one-eighth are now equipped; the others must be provided for, and it will tax the resources of manufacturers, operators and financiers to do it.

During early telephonic days the art was entirely experimental. It was necessary to expend millions of dollars in learning how telephone exchanges should be built. To-day many of lessons have been learned, apparatus is rapidly becaming standardized, telephonic engineers know what and how to construct. Consequently, annual allowances for maintenance and depreciation can be reduced, with a corresponding decrease in the cost of service. Improvements in manufacturing methods cheapen apparatus with a similar result, and as the price for telephonic intercommunication falls, the zone over which telephones may be distributed extends. As more and more people obtain telephones, the telephonic habit grows, for traffic breeds traffic. To-day no business house can afford to be without a telephone and shortly no residence can, so he who runs may read the prophecy for the future.

A significant tendency is the adoption of mechanical appliances in the operating room. The lamp signal removed the manual drop. Machine ringing has relegated the manual ringing key to the scrap heap; self-ejecting plugs are possibilities, and many inventors have proposed, and with some degree of success, operatorless exchanges. In a general way the tendency of the telephone company is to relieve the subscriber of all work and to concentrate every function in the exchange. This appears incompatible with the automatic switchboard, which necessarily must inflict a greater burden upon the subscriber. But the automatic exchange may, and probably will, have a certain and very wide field. To expect the business man to operate a series of levers, or dials to call a subscriber, when he can pick up a receiver and tell his private exchange operator just what he wants, is folly. It is equally foolish to require the Chinese laundry, the corner grocery and the tenement house to pay the rate required by the service needed on Wall street or Broadway. It appears quite possible that some form of automatic exchange may be devised, which will be installed in certain zones of the larger cities, and be entirely adequate for the smaller towns and villages. Such automatic exchanges will work in conjunction with manual exchanges in such a manner that service may be graded to fit the customers to which it is addressed. This is as logical a proposition as for a railway to run Pullman cars, day coaches and immigrant trains. But it would be equally illogical to force all passengers into one train. The service must fit the customer.

The field of the telephone is by no means exhausted. The Electrical World and Engineer has suggested the telephonic transmission of money orders; witnesses are examined and depositions taken telephonically; it is veraciously reported that several engagements and some marriages have thus been consummated; but so far there have been no divorces and no executions by it; so there are yet many opportunities to develop the business in ways perhaps now unexpected.

A keen competition is often regarded as a business blessing; and, so far, telephonic competition has been by no means an unmixed evil. But telephony differs from other commercial undertakings. Usually a wholesale business is cheaper per unit than a retail one, but such is not the case in telephony, for the cost per subscriber in a 10,000 line exchange is greater than in one of 1,000 subscribers. It would not be considered desirable to have two rival post offices, and telephonic service resembles postal service. If there are two telephone companies in one city, either both must interchange messages, or else the subscribers, to get complete facilities, must have two telephones. If the latter, installation costs are doubled, for there are twice as many sub-station instruments, and twice as much wire plant. Hence the cost of service is augmented, for in the end the community pays all the costs and all the profits of running two companies. What shall the solution be? Is it to be municipal or governmental operation like the post office? Will legislation force all telephone companies to interchange all messages? Shall a Utopian state of affairs arise in which one company will so adjust rates as to pay reasonable operating expenses, legal interest on unwatered capital, and no more? or may some form of co-operative ownership be devised in which each subscriber is a stockholder and annually receives any surplus over operating expense? *Quien Sabe.*

The Evolution of the Enclosed Arc Lamp.

By L. B. Marks.

The enclosed arc lamp of commerce dates from the year 1894. For fifteen years prior to that time the open arc held sway. A glance at the arc lamp statistics shows that there was a sudden turning point in the evolution of the arc lamp. The enclosed arc, as if by magic, ousted its predecessor and gave a remarkable impetus to the introduction of arcs, particularly on constant potential circuits.

The question has often been asked, "What was it that brought about this sudden introduction of the enclosed arc lamp?" Was there any new discovery or invention that made possible what formerly had not been accomplished? Surely a host of inventors, both in the United States and abroad, had experimented with the enclosed globe arc lamps ever since the earliest days of arc lighting. The records of the Patent Office will attest this fact. There are some who think that the enclosed arc lamp is simply an outgrowth of the development of carbons—that if we had had a satisfactory carbon in the early days of arc lighting, the open arc would never have held sway so long.

Now, as a matter of fact, satisfactory carbons were on the market continuously for many years prior to the advent of the modern enclosed arc lamp. The price of these carbons was naturally higher than it is now, but not prohibitively high. In some of my work in arc lighting years before the first commercial enclosed arc made its appearance I employed very pure carbons that were admirably suited for use in the modern enclosed lamp. These carbons were manufactured in this country and were sold at a price not exceeding the present price of good imported carbons.

Those who are familiar with the steps in the evolution of the enclosed arc lamp of commerce know that this type of lamp was made possible by the discovery that when an arc is enclosed in a small globe having suitably restricted air inlet, a long arc of abnormal voltage may be steadily maintained by a small current—a condition impossible in free or open arcs. This discovery was followed up by the construction of a lamp that would strike a long arc and maintain it under the proper conditions. Herein, then, lay the secret of the modern enclosed arc lamp. Broadly speaking, that secret was not in the carbon, but in the arc. The solution of the problem, therefore, involved, first, a method of operation, and, second, an apparatus for carrying out that method. So far as the records go, neither the method nor the apparatus was known to the world prior to the year 1893. Once these features were given to the art, the commercial enclosed arc lamp became an accomplished fact.

The First Commercial Electric Street Railway in America.

WHAT a marvelously brief period has sufficed to establish electrical power in full possession of the field of urban passenger traffic, receives a striking illustration in the fact that to a man, to-day but in his fortieth year, belongs the honor of having personally guided the first electric motor for street traffic put in practical commercial service in this country.

The event which marked an epoch in the solution of the problem of the application of electricity to the purposes of passenger traction occurred in the city of Baltimore and the man who stood at the controller of the first practical electric locomotive taking its power from the now familiar third rail, was Guy M. Gest, now a prominent electric subway contractor of New York and Cincinnati, who prizes above all other honors he has won in a career devoted to the development of electric subway work, his undisputed right to the title of "The Father of Motormen," who in spite of his youth now numbers his "sons" by the hundred thousands. The very name "motorman," now so convenient and familiar, had not yet been

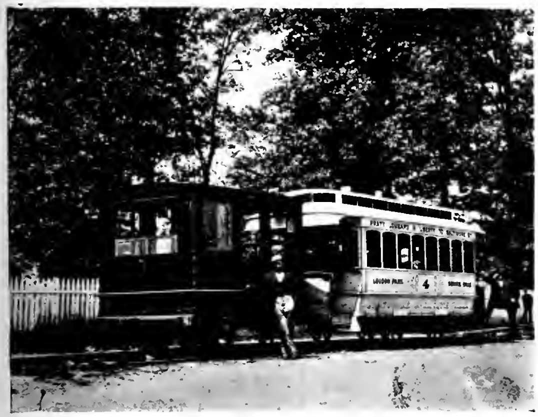

FIG. 1.—DAFT ELECTRIC STREET RAILWAY LOCOMOTIVE.

invented when Mr. Gest piloted the first train of electrically-propelled cars through the streets of Baltimore, his function on that historic occasion being described in the newspapers of the day as that of "engineer."

In connection with this historical performance it is interesting to note that the third rail from which the car derived its power, while laid on the surface between the wheel tracks was so protected from any accidental external contact as to make it practically identical in principle with the modern conduit system supplanting in urban practice the overhead trolley wire, which was the immediate successor of the original third-rail device, thus offering another example of the familiar tendency to a reversion to first principles.

To Mr. Thomas C. Robbins, General Manager of the Union Passenger Railway of Baltimore, belongs the credit of having first recognized the possibility of the successful application of electricity to the solution of the problem of street car propulsion and it seems to have been peculiarly appropriate that the practical demonstration of the correctness of Mr. Robbins' judgment should have been made in the same city which witnessed the first practical test of telegraphy, on May 1, 1841, just forty years earlier. It is also appropriate that the first practical electric motor should have borne the illustrious name of "Morse," the inventor of the electric telegraph.

Electric traction had not yet emerged from the stage of experiment when Mr. Robbins cast about for some efficient substitute for horse power in the operation of his lines and his attention was first called to the startling possibilities of electricity by the performance of a lilliputian exhibition railroad that formed one of the amusement features of Coney Island in the summer of 1884. He consulted with Mr. Daft, the inventor for the Daft Electric Company, of Greenville, N. J., who went to Baltimore, and after a careful examination of the road, declared that there could be no question

FIG. 2.—WYETH SWITCH, DAFT THIRD-RAIL ROAD, BALTIMORE.

of the entire practicability of Mr. Robbins' plan. A contract for the installation of a power plant and the construction of motors was at once entered into, and while two motors were under construction in the shops of the Daft Electric Company at Greenville, under the supervision of Mr. G. W. Mansfield, a power house was erected, adjoining the car stables, equipped with a 75-hp engine and a 50-hp dynamo. The preparation of the track and the laying of the protected third rail and wire connections were undertaken under the direct personal supervision of Mr. H. A. Foster, of the Daft Company. How well the whole work of construction and equipment was performed was fully attested by the complete success, not only of the first trials, but of the subsequent operation of the road. Simultaneously with the completion of the power-house and the track the Daft Company was ready to put into service the pioneer motor, or car, as it was more usually termed in those days, the "Morse" and its companion the "Benjamin Franklin."

There is a quaint flavor of simplicity attaching to the description of this historic machine published in the *Morning Herald* of Baltimore of August 10, 1885, which makes it well worthy of reproduction. Referring to the wonderful "electric engine" the reporter who attended the trial writes: "This is a plain little caboose,

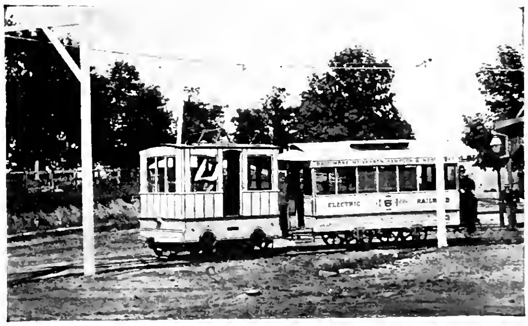

FIG. 3.—DAFT UNDERRUNNING TROLLEY, BALTIMORE, MD.

weighing, with armature, only 4,500 pounds. It is about 8 ft. long and 4 ft. wide and the roof is only 9 ft. from the ground. From the center of this motor, which has been named the 'Morse,' hangs a little brass wheel called the 'contact wheel.' It runs entirely on the center rail, taking up the current of electricity and conveying it into the armature in the forward end of the motor. The current of electricity is administered to the center rail from the dynamo generator in the engine-house by means of copper wires When the contact wheel takes it up from the center rail the armature at once becomes 'excited' and the motive power is transmitted to the axle by means of gearing, and the wheels of the motor are thus thrown into motion. Through the outside wheels the current is then returned to the dynamo generator, thus keeping up a continuous current along the entire length of the road." With the view of reassuring the good people of Baltimore against any suggestion of danger from the mysterious new power the reporter continues: "The electric current is low-tension and no danger of shock will result to man or beast if the rails are touched in crossing or with the bare hands. In the latter case the result is only a slight tingling sensation."

The "Morse" was equipped with a compound series motor rated at only 8 hp. with single-reduction gears; regulated by a primitive form of controller. She was shipped from the shops of the Daft Company at Greenville on June 10, reaching Baltimore two days later, and so advanced were the preparations at the power-house that it was possible to conduct the first private trial of the new motor on the following day, the result giving every augury of the complete ultimate success of the plan. Various details, inseparable from the launching of a pioneer enterprise, remained, however, to be adjusted, and it was not until August 9, at one o'clock a. m., that time being selected in order to avoid popular excitement that would have attended the first appearance of the motor, that the first actual trip over the line was made, under conditions that only varied from those of actual practical service in the fact that the passengers carried, twenty-nine in all, were confined to officials of the railroad and of the construction company and to representatives of the press.

One of the pictures herewith illustrates what must be regarded as one of the earliest and most interesting attempts to use an overhead trolley contact as an alternative to the third rail and as a means of getting by crossings. At one side of the track a series of brackets were erected on poles, the arms being of pine 3 x 4. From these gas pipe was suspended by means of a U-shaped insulator. The contact brush to this overhead trolley consisted of a laminated series of sheet iron, some 6 x 8 in. wide clamped together and fastened to a wood trolley pole, the base of which was connected by an ingenious toggle arrangement to a lever in the inside of the cab, permitting the motorman to raise and keep in contact the brush when passing over the street crossing at which point this interesting and really first demonstration of such an underrunning trolley was used. The motorman by a foot lever raised the third-rail contact wheel and with his left hand controlled the overhead attachment and thus maintained a continuous contact. This arrangement was not added to the original method of third-rail contact until the road had been in operation many months, its necessity was urged on account of animals being injured by coming in contact with the third rail at street crossings. The details of this device were handled by Mr. A. H. Haywood, who took up the Daft Company's interests in Baltimore after Mr. H. A. Foster severed his connection with that company.

The train was made up of the "Morse" attached to one of the ordinary passenger cars. Mr. Gest, who had been identified with every detail of the construction of the motor, stood at the controller and at a signal from Mr. Robbins turned on the power and set in motion this pioneer of third-rail electric trains. The report of the *Morning Herald* tells us: "A brilliant flash of light shot out into the darkness as the contact-wheel fell upon the center rail and a shower of sparks flew right and left and then the motor, dragging the passenger car with its living freight, rolled rapidly out of the yard and sped on its way. A few hundred yards were traversed and then the current was cut off, the brake applied and the train returned to the yard up a steep incline. Back and forth the motor ran again and again, and each time it ran over the rails it improved in its action. Once it ran off the track, owing to a misplaced switch, but it was quickly replaced. Afterwards the passenger car was detached and the motor was run at a rapid rate of speed around curves and over switches with the greatest ease and safety. The trial was a most thorough and satisfactory one, as was testified to by all, and with the exception of a few minor mechanical defects, which can soon be adjusted, the trial perfectly demonstrated the practicability of the motor." It was estimated that the use of electricity would be attended with a saving of over 50 per cent. over that of horses. Later, two other and larger electric locomotives were installed on the road. The average daily run of each was 75 miles.

The attention of the street car companies of New York, Boston, Chicago and Philadelphia and of all the great cities in Europe had been riveted on this epoch-making trial in Baltimore and its triumphant success gave everywhere a tremendous stimulus to the substitution of electricity for horse or cable power. Less than twenty years have sufficed to fulfill the prediction, made by Mr. Robbins and Mr. Foster at the conclusion of the trial, that its success marked the beginning of a revolution in street car propulsion as complete as that wrought in stage-coach traffic by the appearance of Stephenson's locomotive; and to-day, having completely conquered the domain of city and suburban traction, the mighty successors of the little "Morse," driven by Mr. Gest, are threatening to relegate the descendants of the "Rocket" to the limbo of the stage-coach and the horse car.

Speaking recently of the wonderful development of electric subways with a fellow member at the Union League Club, Mr. Gest said: "I was little more than a lad, just about old enough to vote, when I assisted in that almost-forgotten trial of the first electric motor in Baltimore. To my mind it marked the beginning of the era of the successful application of electricity to locomotion and as such the event is worthy of commemoration. I take a keen satisfaction in the fact that I bore a part in it, and as I look back to that small beginning I am astonished at the progress that these comparatively few years have brought about. It should not be forgotten that a very substantial share of the credit for the success that attended the electrifying of the Baltimore road was due to the skill and energy of Mr. H. A. Foster, whose admirable ideas in carrying out the work of construction of the power plant and the track arrangements showed him to be the accomplished electrical engineer that he is. From the beginning, however, none of us who were associated in the work had the least doubt of its complete success, although it is easy to see how, in that early stage of electrical science, there were many unforeseen difficulties to be met and overcome. I do not know whether the old 'Morse' on which I officiated as motorman is still in existence, but if she is I think that a place should be found for her in the National Museum beside the earliest locomotive. Although she took her power from a primitive form of third-rail her performance fully demonstrated the practicability of the electric railway system.

"And apropos of that," continued Mr. Gest, "I am reminded how universally visitors to New York express wonder when they see one of the old horse-cars crawling along one of the side streets downtown. Of course, the reason for keeping these old cars in service is obvious in the economic objections which stand in the way of laying down subway conduits under the conditions that prevail in many parts of the city, but the change is bound to come and sooner or later. With the disappearance of the last horse-car our country cousins will have one less metropolitan wonder to talk about when they go home. I had an amusing illustration of this the other day when I brought my son, a youngster of seven, to New York on a visit. About the first thing that attracted his attention after leaving the ferry was one of the old cars on West Street. He stopped in open-mouthed wonder, for he had only seen horse-cars in pictures, and was only satisfied when I promised that some day I would take him for a ride in one. I thought to myself, 'surely that the world do move' when the son of the man who drove the first electric street motor is curious to enjoy the novel experience of a ride on a horse-car. I shall have to hurry up, before the last car is gone, if I want to keep my word with the little lad."

A Period of Great Development.

By Francis Blake.

In reply to your letter of invitation, I have to say that I am much impressed by the fact that the life of your journal covers the period of the birth and a marvellous development of the science which governs the commercial use of electricity.

If I were asked for specific reasons for this general statement, I should refer my questioner to the volumes of the Electrical World and Engineer which—by their advertisements as well as by their leading articles and their editorial matter—present a most valuable record of this important epoch in the world's progress.

Upon the occasion of your thirtieth anniversary, I congratulate you upon the fidelity and the ability with which your journal has rendered its technical services to the electrical fraternity in particular and to humanity in general.

The Electric Railway Industry in 1883.

By Frank B. Rae.

FIG. 1.—FIRST ELECTRIC RAILWAY TICKET.

The early days of the electric railway business were all twenty-six hours long and loaded with trouble. Motors were puny things in the early eighties. It was necessary to sit up with them nights and give them homœopathic doses of shellac in various parts of their anatomy, tie up the sore places with tape, and devise schemes to hold the armature leads and the commutator bars together for the next day's run.

The things we did not know back in '83, put in book form, would make a Carnegie library look like an elevated railway book stall. This should perhaps be qualified by saying, the things that some of us did not know, etc. There were those who knew all about everything; moreover, they wrote about it in the papers, whereat we of the working force marvelled. Some of these things, re-read to-day, would make most anyone marvel; but one of the real scientific facts that some chap wrote at the Philadelphia Exposition in '84 looms up like the shadow of a great rock in a desert, and has been a daily help and guide. He said: "A dynamo machine may be painted any color without affecting its efficiency." This is as true to-day as when it was written, twenty years ago, which is more than can be said of some of the other stuff.

The first electric railway company in this country, organized to construct and equip electric roads, was, I believe, the Electric Railway Company of the United States, with offices in the Mills Building, New York. This company acquired, or expected to acquire, the railway patents of Thos. A. Edison and Stephen D. Field. It

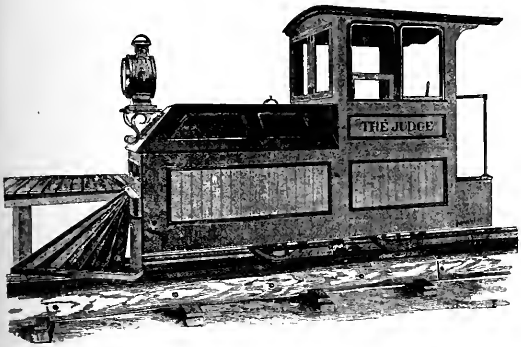

FIG. 2.—THE FIELD ELECTRIC LOCOMOTIVE "THE JUDGE."

was backed by Cyrus W. Field and his associates, with Mr. S. G. Reed, president, C. W. Rogers, vice-president, and Chas. Dimon, secretary and treasurer. Rogers was the active man, and his activity was of the brand that "eboluted" a lot but resulted mostly in hot air. He traveled in a stateroom with a typewriter and a hard-working young chap that was referred to frequently as "my secretary." Letters were mailed at every stop, and confirmed by telegraph. The end came before any real business happened, probably due to the preliminary funds having been used up in postage and telegraph tolls. The company did, however, equip one road, not a very long one, it is true, but it was as broad as some of them, and has the distinction of being the first electric road for business purposes in the United States. One night in March or April of 1883, there was a meeting at the Fifth Avenue Hotel, attended by Edison, Field, Prof. Morton, the engineer of the Northern Pacific road, and myself, the last three being a committee appointed to pass upon the Edison and Field patents, and determine their value to the Electric Railway Company of the United States. After it was over, Field said: "Frank, I wish you would go to Chicago to-morrow, and build an electric road for the Exhibition of Railway Appliances. I have had shipped there two Weston 100 incandescent light dynamos; use one as a generator and the other as a motor. You will find the track down around the gallery of the building, and Mr. J. McGregor Adams will give you any assistance you require." When more details as to construction were insisted upon, Field covered a sheet of paper with drawings and said: "There, put your motor crosswise on a truck, extend the shaft, use a bevel gear to drive a countershaft, put some pulleys on the counter-shaft, and belt to some others on the truck axle. Make a rig to reverse the brushes to reverse the armature, and—there you are."

All this was done, and several other things, before "The Judge," as the machine was called, was ready for service; and this brings us back to the remark above, about things we didn't know in 1883. At least, we didn't know them right off quick. For instance, it required something like twenty-four hours, mostly spent walking along the lake front, to grasp the fact that a shunt-wound dynamo, built as only Weston knew how at that date, would not generate current when started up on a short circuit, *because it couldn't*. It would not do, of course, to throw the shunt-wound motor on to the dynamo after the dynamo started and was up to voltage, so it was provided that the motor should start up with the generator and run continuously, the load being thrown on with a friction clutch on the axle. But the motor refused to start up with the generator, hence the ramble

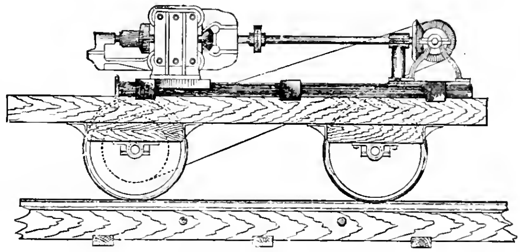

FIG. 3.—DETAILS OF "THE JUDGE."

along the lake front, resulting in making a resistance for the armature circuit of the motor and a switch to gradually cut it out. It is quite possible the board of underwriters would not pass this particular style of starting rheostat to-day. It was constructed of bare soft iron wire wound in grooves, planed into some pine boards, which boards were set on fire four or five times a day, with a regularity that would have been greatly missed, if a modern iron-clad rheostat had been substituted.

This road was a third-rail road bonded with No. 6 copper and had a total circular length of 1,553 feet. The locomotive, Figs. 2 and 3, hauled one car, seating 20 people, and in the ten or twelve days of operation, 26,805 passengers were carried, and $2,680 was earned. All this was comparatively easy; the days of trouble came a few years later, but that's another story.

I believe that the electric railway ticket here shown in Fig. 1 was the first ever printed and issued specifically for electric railway purposes.

Telephony the Greatest Invention of All.

By P. B. Delany.

This paper now and what it was thirty years ago is graphically illustrative of the progress made in electrical science and invention.

To my mind, the greatest invention within, or without this span, is the telephone. The electric light is a priceless boon, the trolley a great utility, wireless telegraphy a wonderful achievement; but the telephone is all these and a blessed benefaction in human affairs as well. Its sublime simplicity and marvelous adaptability, transcend all comparisons in the domain of pure or applied science.

The extension of audible speech transmission from a stone's throw to a thousand miles, and with quieter inflection, is a work unrivaled. The telephone is an allayer of worry, an assuager of sorrow, a life saver, a deterrent of crime, an earnest of security, and an indispensable commercial necessity. The world could better afford to go back to the "penny dip" and the stage coach, than give up the telephone.

As to what the future holds, no man may say; but even though he explores the ambient clouds on a radium motor, with a searchlight for a rudder, the telephone invention will still be secure in its peerless position.

The First Central Station for Incandescent Lighting.

By W. J. Hammer.

SOME years ago while preparing a lecture on Edison's life and his inventions, which I delivered before the Franklin Institute, I asked Mr. Edison what he considered his most important achievement, and he replied without hesitation, "The Jumbo dynamo." Those who are familiar with the early days of electric lighting will remember that prior to the construction of these huge Edison machines there were practically no dynamo machines in existence which could not be lifted and carried around by two or three men, and it was a tremendous step forward from the small machines then generally constructed to the mammoth Edison dynamo, which weighed 23 tons and employed a bar armature weighing 4½ tons.

Those who are familiar with the experimental work at Menlo Park on the Edison bar armature machine and the subsequent construction and testing of the first "Jumbo" machine which was sent to the Paris Electrical Exposition of 1881, will understand and remember the number of times which this machine was taken apart and put together again at the old Goerck Street Machine Works. Those who participated in the sleepless days and nights at that period of great anxiety will understand why Mr. Edison has attached such importance to the construction of this huge dynamo.

I well remember having been entrusted with the loading of this Paris Exposition machine on the gigantic "Ox," the only derrick in New York Harbor which could handle it, and lying all night alongside of the steamer on the North River; and I remember also the difficulty I had in securing the shipment of this machine, which necessitated the risky carrying of the 4½-ton armature upon the deck.

The second and third "Jumbo" machines were sent to England and were installed by Mr. Edward H. Johnson and myself in the 3,000-light central station on Holborn Viaduct, London—this constituting the first central station for incandescent lighting in the world, it having been started on January 12, 1882; whereas the Pearl Street station in New York, the first one established in this country, did not start until September of the same year.

It is probably known to very few where the term "Jumbo" dynamo originated, and I can claim the honor of giving this type of machine this name—and it came about in this way: The two dynamos which were sent to England were despatched on the "Assyrian Monarch," of the Monarch Line, this being the same steamer which had just before that carried the celebrated elephant, Jumbo, which the American showman, Barnum, had purchased from the London Zoological Society, and it occurred to me to dub the first machine "Jumbo" and the second one "Alice," after Jumbo's mate in London; and the name "Jumbo" has ever since characterized this type of machine.

It is interesting to call attention to the fact that this Edison dynamo was the first direct-connected generator. One of those which were sent to London had its armature directly coupled to a Porter-Allen engine and the other to an Armington-Sims engine. I had the honor of first coupling up two of these machines and making one run the other as a motor; and in April, 1882, the two machines which had been alternately used were run together successfully in multiple or parallel, this being the first time that these machines were so coupled. A cablegram was sent to Mr. Edison by Mr. Johnson announcing the success of this test, and subsequently not only two, but three of these machines were run in parallel. There are many who will remember the great difficulties which were subsequently met at the Pearl Street station when efforts were made to run the "Jumbo" machines there in parallel.

The history of the first central station for incandescent lighting established in the world, namely, the 3,000-light Holborn Viaduct station, started January 12, 1882, has never been written. The present occasion offers neither the time nor space to present this matter properly, but I should like to call attention briefly to a few important features connected with this historic plant, which was originally intended as a European demonstration of what Mr. Edison's electric lighting system was, and which was operated long after the time originally proposed. The station had been erected on property belonging to the Crown, and it was impossible to construct the large station subsequently planned. That, together with other electric lighting enterprises, were knocked in the head by the celebrated Electric Lighting Act of 1882, which caused financiers contemplating investments in electrical enterprises to button up their pockets until Parliament should deal with the industry in a more liberal spirit.

It may interest many to know that this station supplied its consumers by a network of feeders and mains of the standard underground two-wire Edison tubing, such as was subsequently used for a long time in New York City, Milan, Italy, and elsewhere. It used a meter system employing the well-known Edison electrolytic meter. Arc lamps were run from these circuits, and I assisted Dr. John Hopkinson in experimenting with Siemens' differential arc lamps, specially constructed for this purpose. I also assisted Dr. Hopkinson in his experiments with his mechanical meter employed experimentally on these circuits; and one of the first sets of "Faure" batteries sent to England was experimentally used at the Holborn Viaduct station.

In connection with this set of "Faure" batteries an interesting incident occurs to me. A small boy passing through the station, whistling a tune and swinging carelessly a hammer carried in his hand, rapped a carboy of sulphuric acid which happened to be on the floor above a "Jumbo" dynamo. The blow broke the glass carboy and allowed the acid to run down upon the field magnets of the dynamo, destroying the windings of one of the 12 magnets, which formed the pole pieces of this machine. This accident happened during a vacation I was taking in Germany, and a prominent scientific man connected with the company cabled Mr. Edison to know whether the machine would work if this coil was cut, and Mr. Edison made the laconic remark, "Why don't he try it and see?" I remember about this period assisting Sir William H. Preece in a lecture before the Society of Arts in which an Edison bipolar machine was dropped off a truck and the winding of one leg of the magnet sot badly cut that I was forced to use the machine with only one leg connected, but it worked with perfect satisfaction, although the machine had to be placed on the Thames embankment a long distance away and controlled from the lecture stage.

Up to the time of the construction of this plant it had been customary to place a single pole switch on one wire and a safety fuse on the other, and the practice of putting fuses on both sides of a circuit was first used here. Some of the first, if not the very first, of the insulated fixtures were used in this plant, and many of the fixtures were equipped with ball insulating joints, enabling the chandeliers or electroliers to be turned around, as was common with the gas chandeliers. This particular device was invented by Mr. John B. Verity, whose firm built many of the fixtures for the English company, and constructed the notable electroliers shown at the Crystal Palace Exposition of 1882.

The streets and bridges of the Holborn Viaduct were illuminated by incandescent lamps turned on and off from the station, and a device designed by my assistant, Mr. Cunnington, was used experimentally for turning on a second lamp should one of the two lamps in the post give out.

Dr. Parker's City Temple was supplied from this station, and was the first church in the world to be lighted by incandescent lamps. I well remember the astonishment of Dr. Parker and his associates when they noted the difference of temperature as compared with the gas. I was informed that the people would not go in the gallery in warm weather owing to the great heat caused by the many gas jets, whereas on the introduction of the incandescent lamp there was no complaint.

The operating room of the General Post Office, a long distance away, was supplied with 400 Edison lamps from the station, and I remember the anxiety of the chief electrician, Mr. (now Sir William H. Preece), when the cables were run through the subway under the Holborn Viaduct in which were placed the cables of the telegraph company, and the authorities were certain that the enormous currents carried in the Edison mains would interfere with the telegraph system mains. They had found this the case when the Jablochkoff system had been installed on the viaduct and the cables run through the galleries underneath. Although Mr. Johnson and I called their attention to the fact that whereas the Jablochkoff people used an alternating current, the Edison system employed a low potential direct-current, with both wires enclosed in an iron pipe, still there were many who were sure that there would be trouble, and on arrangements being made for the official test I remember the astonishment on the part of the telegraph people when I informed them that the current had been on for a good part of a week, and there had been no effect noticed on the telegraph system.

Of course, this was many years ago, and the large size of the mains employed in the Edison system and the previous experience which had been had with the Jablochkoff system naturally caused considerable anxiety.

For throwing the load of lamps from one "Jumbo" machine to another I constructed a huge snap switch, there being 16 metal pawls mounted on a ring of brass, these pawls resting on 16 teeth of the revolving disc. One-half of these teeth were ebonite, and were set into the brass plate which the other teeth formed a part of. Turning the handle of the switch would break the circuit simultaneously at 8 points. There were large rubbing surfaces and powerful springs employed. We also designed the first automatic circuit-breaker ever built, and the drawing of this is still in my possession, although the circuit-breaker itself was never completed.

Early Electrical Days at Cornell.

By Prof. W. A. Anthony.

When I went to Cornell University in 1872, the development of the dynamo electric machine had just begun. Accounts of the Gramme machine had appeared in some of the technical journals. I immediately went to work to design and build one, which served a very valuable purpose in the experiments at Cornell University and I followed with the keenest interest everything that took place in electrical development during those early years.

For convenience in communication with the various departments of the university and the people in the village of Ithaca, a telegraph line was established which finally developed to something over forty offices in 1876, when we began to hear of the telephone. I was immediately interested in that and I think it was early in 1877 I succeeded in obtaining some of those wooden hand telephones, which I connected to this telegraph line, and used them in connection with the telegraph instruments. Very shortly after this the telegraph line was changed to a telephone line, battery call bells and telephones being substituted for the telegraph instruments.

Only a single telephone was used at each office, parties using it alternately as the transmitter and receiver, and many ludicrous incidents occurred from two people attempting to carry on a conversation with each other and both talking at once or both listening at once. This telephone line led to the development of a telephone exchange, which obtained quite a large patronage and employed all-night operators before we had gone so far as to use both transmitter and receiver at the subscribers' offices.

In connection with the early development of electric lighting I remember well returning one night from Washington. The train stopped at Menlo Park, not far from midnight. I saw some incandescent lamps lighted about the grounds. I immediately got off the train to try and see what was going on. Lamps having filaments of the old cardboard carbon were scattered here and there about the grounds and were evidently in use in some of the houses. I found my way to the workshop and to the dynamo room, where one of the earliest of the Edison dynamos was in operation supplying these incandescent lights. On a large table located in the center of the room of one of the work rooms was a Thomson galvanometer with its lamp-stand and scale enclosed by a screen of black cloth so that its indications might be better observed, and this was serving as a voltmeter for indicating the voltage of the machine. Persons about the grounds were calling in by telegraph and making various suggestions about the illumination which the operator at the instrument was endeavoring to carry out, when all at once the lamps began to flicker ominously and finally went out. I went to the dynamo room, to find Mr. Edison himself there in a considerable state of excitement, ordering instruments brought for making a test. It was found when the machine was stopped that one of the coils had burned out. Another armature was in process of winding, but it was hopeless to think of completing that and getting the lights into operation again that night, or rather, morning, for it was getting to be near three o'clock. Mr. Upton, one of Mr. Edison's assistants, very kindly took me with him to his house, which provided for the hours remaining between then and daylight, the disposition of which I had not at all considered when I left the train.

Remembering all this as vividly as I do, the growth of and development of telephone communication and of electric lighting in these later years seems to me a thousand times more marvelous than to those whose memory does not extend back of 1881.

Before leaving Menlo Park I was given a card on which was mounted the punched cardboard horseshoe and inside of it the corresponding carbonized horseshoe showing the shrinkage in carbonizing to be something like a quarter.

The Captains of Industry in the Electrical Field.

By C. J. H. Woodbury.

YOUR reminder of my contributions to the editorial columns of the *Electrician* in 1882 recalls several lines of reminiscence, one of them being that it did not take much to make an editor in those days.

It appears to me that the most notable element in electrical matters, has been that of the men who made all other things possible, that is the administrative leaders in these enterprises. The magnificent figures of the census contained in a recent issue of your journal which stated the present measure of electrical development, caught in its increasing growth like a bird on the wing, may well inspire feelings of reminiscence upon the total development of thirty years. Week by week the advance has been chronicled, and year by year its totals summarized, but the whole term gives an aggregate which furnishes a bewildering comparison.

As the development of Grecian art in twelve years produced the Golden Age of Phidias, so the genius of invention applied to electric lighting, distribution of power and transmission of speech in the years immediately following the establishment of your journal in 1874, were so brilliant as to afford but little opportunity to make any discriminations, but it is worthy of note that all of these inventions were applied to public weal rather than to individual benefit, in the exercise of that true socialism which builds up the interests of all, and does no harm to any.

It is in no sense of disparagement to those electric inventors, whose skill produced the essential initiatives of electrical development, that attention is called to the importance of the type of human skill exercised in that administrative ability which established and operated the enterprises engaged in manufacturing and conducting these electrical undertakings.

The early dynamos savored of the laboratories where they were invented, and it devolved upon others to reorganize the machines to conform to the requirements of factory production, and continuous service.

The lack of suitable supplies for the manufacture of electrical plants created a demand which produced numerous lines of subsidiary manufacture.

The gap in insulating materials between those of submarine cables and of door bell wire was soon filled. The requirements of central station plants for the various electrical purposes have taken the best suited elements of other mill architecture, and blended them into special types of buildings whose permanency is a token of stable, continuous service.

The whole business of the manufacture of prime-movers lost its precedence, and became subsidiary to the electrical demand which required radical changes in steam engine and water wheel to fulfil conditions of improved regulation and economy.

The control of the electrical output to meet the variable demand has developed switchboards and their accessories to an extent which constitutes new systems of mechanical arrangement.

The operation of these plants has in turn required new systems of commercial organization to coalesce the many details required by the public corporation with their privileges from the municipality, in order to give service to the individual consumer intent upon his own wants. This has required a high type of business skill in the operation of all electrical enterprises, particularly in the case of telephone companies where the great number of patrons and the corresponding number of lines of connection has rendered the problem one of infinite detail, in the close relation of the many patrons with the company and with each other. It is in the development of the telephone service to the present standard that American skill has shown to great advantage in comparison with what has been done in other countries in the application of electricity to the service of mankind.

In all of this work beginning with the original devices of electrical inventors, and extending to the application in commercial details of the systems in their respective fields, the pre-eminent service has been that rendered by men whose broad scope was endowed with sufficient imagination to foresee the ultimate possibilities of the demand for applied electricity, and with adequate knowledge of present events to provide for the future by selecting competent men to whom were assigned the tasks of solving engineering problems, and above all, these men were equal to the greatest task of all by their power of inspiring confidence in capitalists who invested the enormous amounts essential for establishing these electrical industries, and in this respect the work of these leaders has constituted the greatest element in this electrical development.

Electrical History and the Importance of Systematic Inspection.

By Ralph W. Pope.

THE gradual advance to the present standard of electrical engineering practice is now so generally recognized that there can be little excuse for the crude construction which is still permitted in various parts of the country. Twenty-five years ago telegraph construction was perhaps the only model, and even the limited experience in that branch was not profited by as it might have been. The original telephone lines were built without regard to permanency, while the electric light lines in our principal cities eventually caused losses of life and property directly traceable to inferior construction that finally led to a public demand that all wires should be placed underground. This naturally led to improved construction, as any other procedure was practically impossible. In spite of the objections to underground work on the part of many of the electrical companies, the best electrical engineers insisted that the problem was largely financial, and their opinions have been justified by experience. Possibly New York City is now the leading example of general underground construction for all classes of service, but even here there are doubts as to the possibility of a conduit electric railway on West Street. The financial return from all classes of service in New York are sufficient to warrant an investment which might be prohibitive in many other cities. Whether underground or overhead construction be adopted, however, proper electric service demands the best, and wherever the population is sufficiently dense to offer a proper field for its establishment, every precaution should be taken to prevent accident which may lead to financial loss through damage suits or diminished revenue.

It is not enough, however, that the original construction in New York should be of the highest class, as the question of proper maintenance is equally important. When everything is new, repairs may not be necessary and if proper care is not exercised there is likely to ensue a period of general break-downs that should be avoided. Frequently an electrical system is properly maintained for years, when a change of administration introduces a policy of so-called economy, and a large proportion of the income previously appropriated for maintenance is diverted to the payment of increased dividends, reflecting corresponding credit upon the new management, while the gradual deterioration of the plant will, in a few years, lead up to extraordinary cost of repairs or possibly reconstruction, which might have been readily avoided.

In most cases periodic inspection will avert many accidents, and gradually lead up to systematic renewal of plant which will insure practically continuous service. Too frequently the inspection is a minor portion of the duties of those who are otherwise engaged, or the inspection and repairs are made under the supervision of one person, or the whole system may be operated until the break-down occurs, and then it may, for lack of time, be fixed temporarily, and subsequently neglected, when the same operation is repeated. Such cases are likely to occur where a manager is loaded down with office work, and while he may nominally look out for weak points in the system, he is practically unable to do so, or prefers to confine himself to the desk and take his chance that everything is all right outside.

The advantage of thorough inspection was impressed upon the writer when engaged in the service of the Gold & Stock Telegraph Company in 1873. At that date this system was probably the highest development of electro-mechanical engineering, for the reason that about 1,000 instruments were required to be in perfect condition in order to give satisfaction to the subscribers. Each inspector was allotted 100 instruments on about five different circuits, and was held responsible for their operation. He was expected to visit each instrument twice a week, and see that it was properly cleaned, adjusted, oiled, inked and supplied with paper. So far as actual visitation was concerned, he could, to a certain extent, regulate his own movements. The circuits being grounded at the end, it was important that the last instrument on each should be examined every morning, after which inspection could proceed according to personal preference. Each inspector was allowed a quota of spare machines kept in readiness by running a short time on a test circuit. Complaints from subscribers were made at the superintendent's office, where they were tabulated by the month, and when the bulletin was posted a bonus of five dollars was paid to the inspector having the least number charged against him. There was an element of chance in this, for an occasional circuit trouble might bring in twenty complaints on one day, while there were occasional instances of a clean score for the month. In addition to the regular force, there was an office inspector, to be sent out on call, while each of the regulars in turn took a day inside. The chief inspector must not be overlooked, as he was the man who was supposed to keep all "keyed up" to a proper performance of their duties, and while at that time his subordinates may not have properly appreciated his electrical and mechanical ability, he was certainly gifted with a microscopic eye, and the faults which the inspectors may have entirely overlooked were duly magnified when entered upon his report of general inspection. The very best of overhead line construction was at that time insisted upon, and when on one occasion the entire system was broken down by a heavy sleet storm, every inspector was detailed to assist in its reconstruction and the orders of the superntendent were to rebuild if possible so that the lines would stand if a similar storm should come along next day.

Having been out of practical electrical work for twenty-five years, the writer is not in a position to state whether similar practice prevails elsewhere, but observation has led to the belief that proper inspection is not universal, and that many serious accidents might be avoided and better and more continuous service provided if serious attention was given to this important branch of service. During the discussion of high-tension distribution at the Institute meeting in December it was stated by one speaker that in a Massachusetts town a high-voltage wire passed through a group of telephone wires only ten inches distant from them. In a New Jersey town the writer every morning last summer passed a frame building where a leading-in "weather-proof" wire was drawn taut over the edge at the end of an iron pipe which ran down into the ground. The attention of a policeman was called to the danger, and he said he would report it and have the wire changed, but nothing was done. No doubt there are many other danger points in the same town which would readily be seen by a competent inspector. While small companies cannot afford to employ expert inspectors continuously, it appears quite feasible for them to combine and obtain their services at regular intervals. Such traveling inspectors would probably be more efficient than local employees, by reason of their wider experience and freedom from the suspicion of meditating injury to the standing of the regular employees, whose work they might be expected to criticise. Such a plan of inspection could be readily systematized by a regular report of faults to be rectified, followed by a subsequent examination, when it could be ascertained whether the work had actually been done as specified.

The Growth of the Sale of Current.

By W. F. White.

The commercial electric lighting and electric railway industries of the world have been created since 1874. Thousands of millions of dollars are now invested in them in the United States alone. The stride is without a parallel. The growth has not been of the mushroom order, but has been a growth with stability. No class of securities withstood the 1893-97 period of financial depression so well as the securities of meritorious electric properties. This record will be maintained. Good electric securities will increasingly win the favor of investors.

The field for the sale of electrical energy is comparatively unexploited. Its sale for general power purposes has only begun. In not a single large city of the United States have the possibilities of the industrial power business been fully developed, much less exhausted. In many of our best cities to-day the gross receipts from the sale of electrical energy for all purposes do not exceed \$1.00 or \$1.50 or \$2.00 per capita per annum. Such volumes of business can be multiplied three, four or five fold.

The existent demand unsatisfied, the great undeveloped market at hand waiting only to be cultivated, insure the future, and guarantee against the effects of even a period of general commercial retrenchment. Come good times, come bad, the electric industries will constantly grow, electric investments will be increasingly profitable and popular, and therefore both commercial and engineering development will continue on the forward march.

The Foundation of the Modern Street Railway.

By Brig. Gen. Eugene Griffin, U.S.V.

You ask for my personal recollection of the electrical evolution of the past thirty years. My personal experience goes back only to 1887, when, as assistant to the engineer commissioner of the District of Columbia, I made a tour through the principal cities of the United States in search of information concerning telephone, telegraph, arc light, incandescent light and electric railway underground wires. I secured a great deal of valuable data on this interesting subject (valuable, in the light of the progress made in burying wires up to that date) and incidentally I became interested in and inspected several electric railways and secured data concerning the same. Upon my return to Washington I made a report to the engineer commissioner (Col. Wm. Ludlow) on the subject of electric railways (December, 1887,) preparatory to the more extended report upon underground wires. My report on electric railways was called for by the United States Senate and published as a public document. I joined the Thomson-Houston Electric Company, of Boston, in March, 1888, and as a result my report on underground wires was never made.

The report on electric railways referred to above shows that in the summer of 1887 there were twenty electric railways in the United States and Canada, viz.: Appleton, Wis., Appleton Electric Street Railway, 4½ miles, 5 motor cars, Van Depoele system; Asbury Park, N. J., Sea Shore Electric Railway, 4 miles, Daft system; Baltimore, Md., Union Passenger Railway Company, Daft system; Binghamton, N. Y., Washington Street & State Asylum Electric Railway, 5½ miles, 6 motor cars, Van Depoele system; Brooklyn, N. Y., 6 miles; Denver, Colo., Denver Tramway Company, 4 miles, 7 motor cars, Short-Nesmith system; Detroit, Mich., Detroit Electric Railway Company, 2 miles, 4 motor cars, Van Depoele system; Detroit, Mich., Highland Park Railway Company, 3 miles, 2 motor cars, Daft system; Gratiot, Mich., Gratiot Electric Railway Company, 1 motor car, Van Depoele system; Kansas City, Mo., Kansas City Electric Railway Company, Henry system; Lima, Ohio, Lima Street railway Motor & Power Company, 6½ miles, 7 motor cars, Van Depoele system; Los Angeles, Cal., Los Angeles Electric Railway Company, 5 miles, 4 motor cars, Daft system; Mansfield, Ohio, Mansfield Electric Railway, 4½ miles, 5 motor cars, Daft system; Montgomery, Ala., Capital City Electric Street Railway Company, 12 miles, 14 motor cars, Van Depoele system; Port Huron, Mich., Port Huron Electric Railway Company, 2¾ miles, 3 motor cars, Van Depoele system; St. Catherines, Ont., St. Catherines, Merriton & Thorold Street Railway Company, 6 miles, 12 cars, Van Depoele system; Scranton, Pa., Scranton Suburban Railway Company, 4 miles, 7 motor cars, Van Depoele system; Wichita, Kan., Wichita, Riverside & Suburban Railroad Company, 4 miles, 6 motor cars; Windsor, Canada, Windsor & Walkerville Electric Railway Company, 1½ miles, 1 motor car, Van Depoele system; Woonsocket, R. I., Woonsocket Street Railway Company, Bentley-Knight system.

There were 22 roads being constructed or under contract, including the Sprague road in Richmond, Va.

This was the very beginning of the modern electric railway development. I became general manager of the railway department of the Thomson-Houston Company, and on the 4th of July, 1888, we started our first car at Crescent Beach, Mass. This car was equipped with two F. 20 (10-hp) motors, which were the first Thomson-Houston motors built for railway equipments. (The Thomson-Houston Company had previously built several motors of different design for the Bentley-Knight Company.) In the fall of 1888 the Eckington & Soldiers' Home road was constructed in Washington. This road was a long step forward in the progress of the electric railway. The overhead line was installed with center poles, a very neat and attractive looking construction.

Then we made our great contract with the West End Street Railway wherein we agreed to keep the apparatus on the cars and the overhead lines in good working order at three cents per car mile. This guarantee ran for five years and was a very serious undertaking for an electrical manufacturing company to assume at that time. Within two years, however, the West End Company found it to their advantage to relieve us from this guarantee and to take over the maintenance themselves.

Sprague's Richmond road, the Eckington & Soldiers' Home road, and the West End road may be regarded as three of the stepping stones on which the electric railway business crossed the stream of possible failure and landed safely on the side of success. Within two years, i. e., in 1890, the railway business of the Thomson-Houston Company had grown from nothing to nearly $4,000,000 per year. We were unable to meet our customers' demands.

During the period of sixteen years in which I have had general charge of the electric railway business of the Thomson-Houston and General Electric Companies, the industry has developed from a total of about 100 cars electrically equipped (in the United States) in 1887, to a total of about 55,000 cars electrically equipped in 1904; from a 10-hp motor per car in 1887 to two (and even four) 200-hp motors per car in 1904; from the small "bob-tailed" car of 1887 to the 48-ton, 60-ft. interurban car and 2,250-hp electric locomotive of 1904. It has been an interesting development. I regard myself as fortunate to have been connected with a development which has added so much to the wealth, happiness and comfort of mankind.

If I were asked to summarize the improvements made in electric apparatus for street cars since 1887, I should do so as follows: Large motors, single reduction motors, enclosed motors (waterproof), increased number of poles (reducing weight), form-wound armature coils, ironclad armatures, carbon brushes, casings to permit gear and pinion to run in oil, series-parallel controller, circuit-breakers, underground working conductors.

Practically all of the elevated and underground railways in the world have been, or are being, equipped electrically. Suburban roads have been constructed and are operating electrically where no roads would have been built but for the advent of electric traction. One of the large trunk railways has already contracted for an electrical equipment to operate not only its suburban service in the vicinity of New York, but also its express service within a radius of forty miles of New York City; other trunk lines are preparing for the execution of similar contracts, and it is only a question of a very few years when the steam locomotive will have disappeared from the vicinity of New York City. Similar results may be expected in other large cities. It is then but a step to extend the electric service to cover all transportation between the large cities of the East, and it is by no means improbable that many of us will live to see the day when the steam locomotive is as much of a rarity as is the horse car to-day.

An Era of Central Station Underground Work.

By John Langton.

A feature in the history of electric lighting, which now runs some risk of being forgotten, is the important part played in the development of central stations in large towns, by the Edison system of underground conductors, known as "electric tubes." The Pearl Street Station in New York, with its low voltage, large current and a considerable area of distribution, necessitated unprecedentedly large conductors which no existing system could adequately supply. Overhead wires would have been intolerably cumbersome, even had they not been barred by the permanent character of construction which was aimed at, and which could only be achieved by underground distribution. The service to be given was strictly analogous to the supply of gas and water, and Mr. Edison's idea of iron pipes containing insulated copper rods, to be manufactured in fixed lengths and joined together in the trench, was characteristic of his direct mode of thought. Their construction and the development of details were confided to the remarkable mechanical skill and judgment of the late Mr. John Kruesi, whose resourcefulness and indomitable perseverance overcame the faults and troubles inseparable from a first essay in a new field, and under whose direction a flexible, reliable and well-standardized system of underground conductors was produced which covered a wide range of sizes. The larger Edison stations constructed in the middle 80's were made possible by electric tubes. No cables then available could stand the severe conditions which the tubes successfully met. Hence, electric tubes did yeoman's service in the early demonstration of the commercial possibilities of central station work; possibilities which justified the construction of conduits and stimulated the production of cables. It is safe to say that the present wonderful development of central station work would have been several years delayed but for the share taken by electric tubes in the pioneer work of electrical distribution from large central stations.

The Development of Telephone Engineering.

By Angus S. Hibbard.

I should consider the thirtieth anniversary of your journal an appropriate time to remark upon the widespread and ever-growing appreciation of the telephone which has scarcely passed its quarter century mark. Born a marvel in electrical art, treated at first as almost an experimental freak, the telephone in its early years traversed a hard road. Unknown and unnamed obstacles obstructed it. New electrical terms and laws were pushed into existence by means of it. Difficulties of all kinds and descriptions were encountered and surmounted by an enthusiastic and devoted band of men of America, who first earned for themselves and gave to the world the title of telephone engineer. With no past experiences to guide them, these men made technical and electrical history as they advanced. Their years of labor have cleared away electrical and mechanical difficulties as they have arisen. The telephone has, by reason of their work, been proved to be the great time saver, and it would be difficult to exaggerate the millions of hours saved daily by the millions of people who now avail of its service. Ever ready at hand, on the desk, in the room, by the fireside or bedside, the telephone, by reason of skillfully designed systems and well-trained service brings, in America, the greater part of a continent within speaking distance. Ten years ago a city having 10,000 telephones in service led the world. To-day there are several single offices in New York or Chicago accommodating the service of more than 10,000 instruments. The tremendous value to the public of such an extended and unified service can scarcely be overestimated. New York with 120,000, Chicago with nearly 80,000, Philadelphia, Boston, Brooklyn, Cleveland, Cincinnati, St. Louis, Omaha, Kansas City, Minneapolis, and all other leading cities of the country, following closely in good proportion to their population, these and more than 20,000 other cities, towns and villages directly connected by long-distance lines, all within earshot, represent an intercommuncating service and system never before equaled nor even dreamed of; while the Pacific Coast with a system of more than 40,000 telephones, centering in San Francisco, is equally developed throughout an area nearly 2,000 miles in extent.

It is not inappropriate that these hundreds of men who have devoted themselves untiringly to the work should at this time review the great and accomplished factor they have been building, nor that others in contemplating it should realize that it represents to-day the accomplishment of that devoted and able technical force now widely recognized throughout the country as telephone engineers.

The First Edison Isolated Lighting Plant on Land.

By Fred'k A. Scheffler.

You ask me to give you some personal reminiscences of interesting periods or occurrences in regard to my connection with the electrical business. I cannot recall anything perhaps which will be of more interest than to state briefly an outline of what I believe was the first private house isolated plant installed by the Edison Company twenty-two years ago.

This plant was put in Mr. W. H. Vanderbilt's residence, corner of Fifth Avenue and Thirty-first Street, during the summer and fall of the year 1881. It was located in the basement of the beautiful new mansion, which he completed about that time.

The appurtenances consisted of two 60-light old "Z" type Edison dynamos, having a combined capacity of 120 16-cp, 110 volts, with a countershaft on the floor connected by belts to two 6½ x 8 high-speed Armington-Sims engines. The steam was supplied to these engines from a locomotive type of boiler designed especially by the writer to fit the circumstances and the space available. It was built by the Baldwin Locomotive Works, and covered with wood and Russia iron lagging with brass bands.

The house was wired for over 1,000 incandescent lamps, 16-cp each, and as it was the intention even as far back as that date to supply eventually that part of the city with current from a central station, the mains were carried in the vicinity of the street for future connections; and as the wiring was done on the old two-wire system, these mains consisted of a bunch of small wires of such a number that the combined size of each main was about three inches in diameter.

As it was impossible to operate more than 120 or 130 lamps at any one time from the isolated plant, the various rooms could not be lighted at the same time, and this would have proved to be a decided annoyance to the owner, if the plant had remained in the building for any length of time. For the purpose of illustrating what could be done with electric lighting for private houses, the results obtained were eminently satisfactory. The arrangement was objectionable from the standpoint of the owners, particularly the ladies, who did not like the idea of living in a house where there was so much noise from the machinery, and especially with a boiler carrying 120 pounds of steam pressure. The whole machinery was removed by the Edison Company before the owner ever occupied the residence.

One very interesting result of the test and exhibition of this lighting plant occurred one evening when the owner and friends had been invited to make an inspection. Just before the visitors arrived, tests of each room were made by turning the lights on and off from the switches located at convenient points on the walls of each room. Everything was found perfectly satisfactory, with the exception of one room on the second story front facing Fifth Avenue. This room was beautifully decorated with "cloth of gold" on the walls. The lighting was effected by single pendants upon the ceiling and two or three side lights or brackets. The latter were combination fixtures, arranged with wires to light the gas also by electricity. In this room when the switch was turned on the most beautiful effect was noticed of the current traveling all around the room on the wall and in one place this "cloth" was cut from a side bracket down to the wainscoting as clean as though it had been cut with a knife. It was, of course, discovered that there was a short-circuit between this particular bracket and some other part of the room; but whether the fault was due to defects in the Edison circuit, or to the plumbers who installed the gas fixtures, or to the parties who put in the gas lighting wires, could not be discovered. The Edison Company paid for a considerable amount of repairs which were necessary to the decorations in the room.

The Field as Seen by One Who Worked With Farmer.

By George A. Hamilton.

I want to congratulate the Electrical World and Engineer on the completion of its third decade in electrical journalism; on its magnificent success—the compensating return for the sacrifice made by its founder—and on its active and faithful chronicling of the marvelous electrical progress that has been made during this period.

When I recall that thirty years covers almost the beginning, development and maturity of the electrical industries of to-day, I find it difficult to realize the fact. Yet such it is. All are, with slight exception, embraced within the lifetime of this publication.

The dynamo had made its appearance only a little while before. Previously, too, the telegraph and electroplating occupied almost alone the entire electrical field.

At that early day it was my good fortune to be associated with Prof. Moses G. Farmer at Boston. He had simultaneously, with Wilde, applied the self-exciting principle to the dynamo and was then actively engaged in the manufacture of various types of machines for electroplating, lighting, torpedo and telegraph work.

At this time, too, Prof. Bell began his preliminary experiment, which later gave us the speaking telephone. I was an enthusiastic participant in some of these, and recall with interest now the fatherly caution then received, not to allow myself to be unduly carried away by some of his theories.

The giant strides that have been made in so many directions since are familiar to all. They have been duly noted in the Electrical World and Engineer and in its contemporaries. Few then realized the force and the magnitude to which these varied interests would attain or realized the vast amount of capital they would employ. Tesla's communication with Mars, in fact, appears hardly less possible now than wireless telegraphy, for instance, did then. Loomis meanwhile has been forgotten.

It is but a step to speculate on the future. Will the next thirty years show progress as remarkable as the past? Who can say? At the beginning of the period just elapsed there were comparatively few workers in the field. The number to-day is multiplied many times over. They are young, energetic now, far better equipped, theoretically at least, than their predecessors. They have, moreover, the incentive of the latter's accomplishments and emoluments before them. It would be strange, indeed, if they failed to score high.

Success to them! Success and long life also to the ELECTRICAL WORLD AND ENGINEER, that it may continue to record and promulgate their achievements as well!

An Era of Electrical Expansion.

BY HENRY A. REED.

I wish first to congratulate you that you were not born earlier. As great men depend for development upon great opportunities, which great events furnish, and the favorable issue of great events depends upon the genius and fidelity of the great men whom they arouse to action, so a great journal to succeed must be called into being by necessity and must minister to that necessity. Prior to your advent, electricity was used commercially only in telegraphy and the principles therein involved, or at that time being discussed, were not sufficiently great, intricate or numerous to inspire, or the dependent industries sufficient to support, a first-class electrical journal. The developments which rapidly followed furnished plenty of material for your consideration, and from the general appearance the commercial results have kept most of your attachés far removed from the want of worldly comfort.

The different system of multiplex telegraphy were being more discussed, the arc light was demanding recognition by capitalists, and in 1876 the success of the telephone was established by its exhibition at the World's Fair in Philadelphia. In 1879 Edison had the incandescent light in commercial shape. A little prior to this date he had perfected the electric pen and had introduced the phonograph. All of these and other inventions relative to light, heat and power required factories for the manufacture of the instruments and attachments necessary for their operation and supply stores for their distribution among the numerous and eager customers.

The effects of the magical powers of electricity were nowhere more noticeable at this time than upon the people. It seemed as though everyone not fossilized was electrified and ready to swallow almost any kind of a pill with an electric coating.

Prior to your advent very few of our schools or colleges had special courses in physics. Civil engineering had been taught at West Point and at the Troy Polytechnic for several years, and Stevens Institute of Technology for mechanical engineering had been opened in 1871; but the rapid developments in the science of electricity demanded not only organs but more schools, and our colleges and universities in great numbers vied with each other in their haste and in the completeness of equipments to meet the demand. Well do I remember when the degree of Civil Engineer was scarcely known in this country.

Our old surveyors could run boundary lines or levels for canals and railroads, but knew little about building bridges or dams. High Bridge and the first Croton dam were built about 1840, and considered the greatest engineering works of this country. High Bridge answered its purpose, but the dam was carried away by the next spring freshet, because the foundation was not properly secured.

Since railroads must have bridges, and rivers must be dammed, the young men who were competent to superintend the operations could wear high collars and flowing sleeves (then the rage) which few of their companions could afford. The result was that the Troy Polytechnic was crowded with young men dreaming of high collars. This may have had something to do with starting the great collar industries in that city. Unfortunately, for some of the young men, railroads did not multiply as fast as civil engineers, and before your début the market was overstocked with the latter.

The rapid development of electrical inventions and electrical industries have had a similar effect upon the young men coming upon the stage during your existence, and an over-abundance of electrical engineers might seem to be feared. But by expansion and imperialism our country is much larger and richer than at the time of the civil engineer boom, and there appears to be plenty of room at the top of the present ladders, with higher peaks already in sight awaiting for ladders and for men.

That the ELECTRICAL WORLD AND ENGINEER may keep in the future as it has kept in the past, abreast of the front line in every advance, is the earnest prayer of one who was in the harness a quarter of a century before your advent.

The Evolution of Dynamo Design.

BY DAVID B. RUSHMORE.

THE science of dynamo design dates from the discovery, by Faraday and Henry, independently, of the law of electromagnetic induction, which states that the electrical pressure generated in a coil of wire, by relative motion between it and a magnetic field, is directly proportional to the rate of change of interlinkages of turns and lines of force. The evolution of this science has been a steady growth in which a process of continual differentiation has taken place. An increasing knowledge of electrotechnics and of the qualities of material employed, has given an ever-growing precision. Applications to numerous fields for the transmission of power and intelligence have given to dynamo machinery and allied apparatus a field of utilization never before equalled, and the stimulus of a world-wide competition has transformed the subject from one of technical interest to that of a commercial consideration of the greatest financial importance.

The original apparatus contained the embryo of the present alternating-current transformer, but the infant dynamo appeared so soon afterwards that both may be said to date from the year 1831.

LIMITS TO DESIGN.

As electrical machinery is designed with regard to the limits imposed by the conditions of operation, it is at the factors affecting such limitations that we should look to understand the lines of development on which progress has been made. An increase in temperature under load, due to energy losses in copper and iron, is found in all electromagnetic apparatus, and the point at which the insulation is injured determines the maximum allowable heating. Besides this common attribute that of regulation of voltage in generators and of speed in motors is next in importance. All commutator machines, both direct and alternating current, have, as a property of first importance, the subject of satisfactory commutation. Standards have undergone great change. What was satisfactory fifteen years ago in regard to the heating, regulation and commutation of dynamo machines would not be accepted to-day. Also in different countries, and with different manufacturers and users in the same country, the requirements in these respects varied widely. Fortunately, engineering societies are fixing the standards for classes of apparatus and conditions of service, thus bringing about uniformity in regard to designing limits.

DIRECT-CURRENT GENERATORS.

The limiting conditions in design of direct-current generators are, in order of their importance, commutation, heating, regulation and efficiency.

Commutation.—Faraday's first machine, shown in Fig. 1, was a unipolar. The simple collecting rings of the early machines were easily changed to two-part commutators. The many interesting experimental machines which formed steps in the early development had little of real design about them. The mechanical construction of the commutator, now one of the greatest arts in dynamo building, was the source of much trouble as machines increased in size. Different materials, iron, brass, gun metal and various alloys of copper were used for bars, and a still larger variety of insulating substances between segments before copper bars and micanite insulation became standard. Sparking was regarded as a necessary evil and as long as the machine operated at all it was considered more or less satisfactory. The early magneto machines, as well as those of Siemens, Pacinotti, Gramme, Brush and Thomson, possessed great armature inductance, but where the outputs were small this caused no serious sparking; and, when it was necessary in the larger generators, special means, such as air blasts at the brushes, were used to prevent harm. When the manufacture of dynamos reached a commercial stage, about the only point in design which was considered, was to keep the pole arc down to a certain percentage of the pitch. These machines, such as the Edison bipolar type, were surface-wound, smooth-core armatures with large magnetic air-gaps and the brushes were shifted with load when necessary.

Designers then began to study armature reaction and a large number of different pole constructions were tried. A rule used in designing was to keep the induction in the air-gap under the weakened pole corner above 1,500 for drum armatures and above 2,500 for ring armatures. The maximum voltage between bars was fixed, but as this is in reality no criterion of commutating ability, it naturally varied greatly, being taken later at about 25 volts for an average value. A careful study was made of armature reaction, and maxnetic air-gaps were then proportioned to give desired relations between armature reaction and field excitation at full load. Also the amperes per inch of armature circumference were used to judge commutating ability. Railway work, with its suddenly varying loads and calling for fixed position of commutation introduced the carbon brush. High resistance commutator leads were tried and a great number of special armature windings, such as the Sayers, and commutating lugs and pole face windings, as in the Thompson-Ryan machine. A careful theoretical study of the very complicated phenomena of commutation was made by several men, among whom must be mentioned Prof. E. Arnold, and the various factors which affect this action were expressed mathematically. The inductance of the armature coil while passing through the period of commutation, was discovered to be of vital importance and many experimental results and rules deduced therefrom have been published. The computation of what is termed the "reactance voltage" of the armature coil is now one of the important determinations in the present design of direct-current machinery. By making a few allowable assumptions

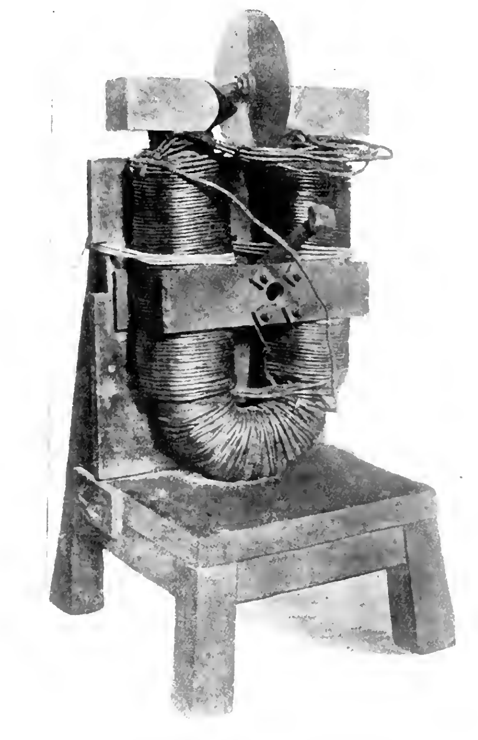

FIG. 1.—FARADAY'S FIRST MACHINE.

and where we have but one turn per coil, the reactance voltage is conveniently expressed by the formula:

$$E_L = 2.5 \times 10^{-8} \times N_B \times S \times I_c \times l_c''$$

E_L = reactance voltage, N_B = no of bars in commutator, I_c = amperes per conductor, l_c'' = length over armature iron in inches, and S the revolutions per minute. A large number of generators and converters have been designed using this rule, and it has been found very satisfactory. It must be remembered, however, that it considers but one of the factors, and the limiting value will vary with such quantities as percentage of pole arc, distortion of field from armature reaction, kind of armature winding, number of conductors per slot, number of segments covered by brush, form of slot, ratio of length of idle to active conductor, kind of brush and resistance of armature coil, commutator leads, brush contact, etc.

The subject of commutation is now one of great theoretical and practical interest, especially since the appearance of the alternating-current series, repulsion and compensated motors with commutators. A very careful study is at present being made and the theory has advanced far beyond the point here indicated. It is now possible to pre-determine the curve of current change in the coil with fair precision, and when this can be done the subject has passed from empirical rules to the domain of exact science.

Heating.—All electrical machines are subject to heating and in many cases the output is limited thereby. It is the result of inevitable copper and iron losses—either of which may be nearly constant or vary as some function of the load—and the temperature reached must not exceed the point where insulation receives permanent injury. Generators, motors and transformers are now designed in this respect with attention to the particular conditions of operations.

Early machines were designed for heating by fixing the current densities, and temperatures reached were abnormal. The field coils were in some cases covered with heavy rope and protection from mechanical injury took precedence over heat radiation. The large number of magnet designs used required field coils of various forms and constants for temperature rise varied accordingly. Rules for the determination of magnet windings for given heating and magnetizing power have been and are still numerous, although applicable, with precision, only to machines similar to those from which the data were obtained.

Multipolar construction did much to improve field coil ventilation. The poles have been lengthened to allow exposed ends on both shunt and series coils, bobbins have been removed, and ventilation secured inside the coil by using round coils with rectangular or elliptical poles, heavy shunt coils have been ventilated by dividing them into two parts, making four exposed ends, or by leaving a cylindrical space one-half inch wide lengthwise through the middle of the coil. The varnished round wire has, wherever possible, given place to square and in some cases where the round is used the interstices have been filled with a compound to aid in conducting heat from the center of the coil. By painting the coils black radiation is at its best, and by placing ventilating ducts through the armature, and especially at the ends, also by considerably raising or sinking the fibre wedge in the armature slot to make the cylindrical surface rough, and by running the core at a high peripheral velocity, a maximum quantity of air is circulated most efficiently around the field coil and the dissipation of heat by this means is obtained with the highest degree of effectiveness.

Excepting the pre-commercial forms and arc light machines, the early type of armature was a long, smooth core, covered with wires and the cross connections lapped irregularly at the ends. The heating of different coils varied greatly and the iron core was entirely covered by the winding. Multipolar types allowed internal core ventilation, brought about symmetrical and well-exposed end connections, and increased the armature diameter while diminishing the length. Toothed armatures exposed the core surface, brought some ventilation through the exposed ends, which was increased when the supporting flanges were omitted, and brought the winding and core more closely in contact, thus equalizing the temperatures between the two parts. Increase in capacity necessitated ventilating ducts in the core and these have been increased in number, and in efficiency, by dispensing with the cast plate supporting the separating fingers and attaching the latter directly to the extra heavy adjacent laminations. By proper mechanical construction the direction of the currents of air set in motion by the armature has been guided so as to give a maximum cooling effect for the energy lost in windage. Great reduction in heating and increase in output have thus been obtained by extensions of the armature end plates and by webs placed on the arms inside the core and on the outside of the end plates under the open cylindrical surface of the cross connections.

BRUSHES AND BRUSH HOLDERS.

Excellence in electrical design is of no avail unless accompanied by goodness in mechanical construction of commutator and brush holders. The necessity for using insulation in its construction, the considerable mechanical stress to which it is subjected and the great variations in temperature which it must undergo, all tend to make the large commutator the part of dynamo construction requiring the greatest care. The electrical design of commutators has had to do with voltage between bars, with numbers of bars between brushes and pitch on commutator, with current density at brush contact, with best brush pressure for the peripheral velocity of commutator, with the heating from friction, contact resistance loss and stray eddies, with the insulation of the segments from the spider, the thickness of the segments and insulation between them. Refined electrical commutator design is of recent origin. A great many machines have been designed by assuming the volts between bars, width of brush and contact density. It is true with low-speed commutators, which existed before the days of converters, this may have been satisfactory. It is, however, at present necessary to make a detailed calculation regarding the heating of the commutator as well as the conditions of commutation.

The use of brush resistance as a factor for successful commutation has changed the metal brush to one of carbon. Here for the last decade a refinement has been in process to suit the resistance, size and lubricating qualities of the material to the special conditions under which the brush is to be used. Carbons and graphites, with various mixtures of lubricating compounds and cementing materials, with and without copper gauze as the carbon, and having undergone various heat treatments, are now the material used for nearly all brushes.

The early brush holders were simple, giving pressure to brush and affording contact for taking off the current. The history of this device shows a wonderful fertility of invention from which a few simple forms have survived. The subject is one requiring illustration for treatment.

DIRECT-CURRENT ARMATURE WINDINGS.

The subject of armature windings may be said to date from the inventions of Pacinotti and Gramme. The ring-wound armature was followed by drum and disc types. A large number of ingenious and interesting windings have been devised. With large outputs but few of these have been successful and in this country but two or three varieties are seen. The possibilities of connections with different armature windings has been thoroughly worked out, principally by E. Arnold, and equations for many possible arrangements have been given. When the conditions for commutation are considered only the simplest types of windings are practicable. Parallel and series or lap and wave windings are the only ones which give satisfactory results. European makers still employ combinations of these, but in this country such exceptions are seldom found. Chord and pitch arrangements of coils are used, dependent upon manu-

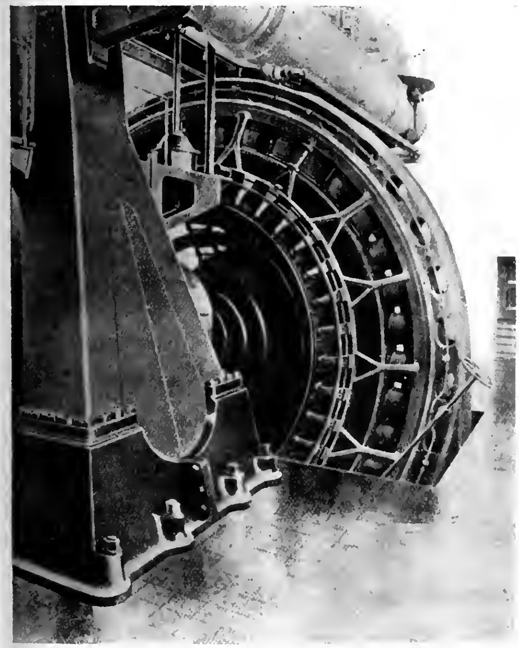

FIG. 2.—3,700-KW GENERATOR.

facturers, type of machine and subdivision of winding. When outputs began to exceed a few hundred kilowatts, the series winding became impossible and parallel windings have needed equalizing rings. The use of these is general and is very satisfactory. Modern designing is characterized by subdivision of reaction and heat generation, so we have small conductors, with but few in a slot, many poles, smallest possible number of turns per coil, maximum numbers of bars between brushes, large diameters, short lengths, small sections, etc.

DIRECT-CURRENT GENERATORS.

The form of field magnet has undergone great change. The two-pole wrought-iron structure has been changed to almost every possible shape by different makers. The greater economy in use of material in multipolar types for large sizes has resulted in the standard

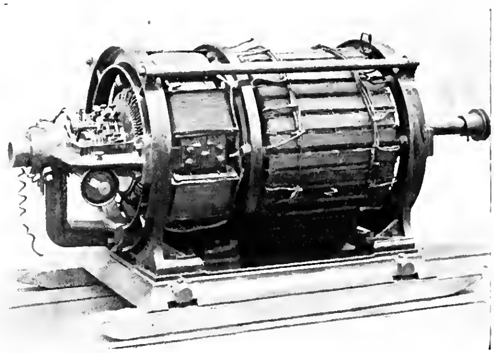

FIG. 3.—REVOLVING-FIELD GENERATOR WITH DIRECT-CONNECTED EXCITER, BUILT IN FRANCE ABOUT 1880.

form of to-day. Curiously enough, some English manufacturers still cling to the old bipolar construction for large units.

Wrought iron was at first almost exclusively used for magnets. This was followed by combination circuits of which cast iron formed a part. The art of casting steel is of recent development and has had a wide application. The best steel castings are now magnetically equal to wrought iron. The critical saturation point of steel, its greater conductivity for eddy currents set up by a varying flux, the disparity between necessary sections for magnetic and mechanical reasons with large diameters, some uncertainty with regard to its manufacture and a lack of magnetic retentiveness and stability have caused some manufacturers to substitute cast iron for its use for field yokes, while for pole cores it is still employed. Rectangular laminated poles cast into iron yokes are also used.

External revolving armatures have almost disappeared. Complications in design of special pole shapes, compensating windings, peculiar magnet forms and unusual armature and field windings continually appear, but as yet none have been able to supersede the simple form which is standard to-day.

ALTERNATORS.

Formerly engineers were divided into two classes in regard to the form of current supply which they advocated, and many were the controversies as to the relative merits of direct and alternating currents. The wide application of the latter awaited a successful motor.

In this country the first commercial alternators had smooth-core armatures with flat pancake coils, external yoke and radial internal poles. The periodicities used were 125 and 133 cycles. These machines ranged in output from approximately 50 to 200 kw. The yoke and poles were of one piece of cast iron and owing to the single-phase reaction became very hot. Owing to limitations of pole forms for these high frequencies, and also to the fact that the armature cores were surface-wound and mechanical conditions necessitated certain clearances, these early machines were possessed of excellent regulating properties.

The pulsating single-phase armature reaction made it desirable to use laminated poles, which were cast into the iron yoke. Wear of bearings which allowed the winding to strike the poles, or the accidental falling of some small body on the armature core, would so completely strip off the surface winding that the next change was to use an armature having as many large teeth as the field had poles and to place the wire in large coils on these teeth, pressing them under the extended edges and holding them in place by wedges driven between two adjacent coils. The first so-called polyphase machines in this country consisted of two such single-phase machines with armatures displaced with respect to each other. While a great advance mechanically, the concentrated armature winding and the great pulsation in reluctance of magnetic circuit gave bad regulation and a very irregular wave form. An alternating-current generator of this type for series arc lighting was developed, by giving it an abnormal armature reaction. The "plus two type" of polyphase generator, in which the armature had two teeth more than the field had poles, was developed and with these was tried a compounding of the machine by use of a series transformer, a two-part commutator and an additional field winding. The increasing demand for polyphase machines and the necessity for good wave form and regulation brought about a distributed armature winding, the frequency in the meantime dropping to 60 cycles.

At about this time a great jump was made and the Niagara type of generator with its internal stationary armature and the umbrella like external revolving field with inwardly projecting poles brought with it the use of 25 cycles.

The last step in the development of this type of alternator has been to make the armature external and stationary and to revolve the internal field. This construction allows the armature to be wound for high voltages and to possess an unbroken electric circuit. The wire field winding has been changed to a copper strip bent edgewise, and with the improvements in mechanical and electrical design we have the present excellent revolving field generator.

In Europe the course of evolution has been somewhat different,

FIG. 4.—MODERN ENGINE TYPE OF REVOLVING-FIELD ALTERNATOR, 2,000 KW.

embracing as it did such types as those of Mordey, Ferranti and Kapp. The result has, however, been the same.

Many different devices for compounding of alternators have been devised, but these have in most cases been extraneous to the generator.

The inductor alternator was early in the field and was for a time decidedly superior to machines which existed contemporaneously with it. The absence of moving wire and sliding contacts, the external stationary armature, the single field coil with its small waste of energy, the almost perfect wave form, excellent regulation, high efficiency, good ventilation and capacity for standing abuse of all kinds, gave it decided advantages. To those who follow closely the development of any path of progress, the influence of fashions as opposed to reason cannot but be apparent. So the fad for revolving-field generators which existed in this country and abroad is now giving place to a reasonableness which leaves the inductor alternators admittedly superior in some fields, equally as good in many and inferior only in few. This refers to the nature of the machine. Comparisons of specific designs can be fairly made only when all factors are considered.

Early generators were of the belted type and 200 kw was considered a large unit. Then came a demand for engine-driven sets, which was reasonable within certain limits, but which for combinations of small output and high frequency was an expensive taste to gratify. Water wheel sets have been made for speeds determined in general by hydraulic conditions and these have and always will be, to a considerable degree, special machines; 300 kw is near the limit for belted machines. Engine-driven alternators have been made up to 5,000 kw and over 40 ft. in external diameter, which is probably the limit as regards size. The new turbo-alternators which promise soon altogether to displace the engine units, naturally run at much higher speeds and are smaller in dimensions; 10,000 kw has been the largest water wheel alternator built.

From the early periodicities of 125 and 133 cycles, the change came to 60 and 66 to allow the use of motors and to save in line inductive drop. The Niagara installation and the use of converters introduced 25 cycles and the projected use of series alternating-current motors has caused one plant to be designed for about 17 cycles. Many generators have been built for odd frequencies as 62.5, 50, 40, 33 and 30 p.p.s. Abroad 50 and 100 cycles are the common usage.

The most important characteristic of the alternating-current generator is its property of inherent regulation. With but few exceptions this largely determines the design. Formerly a large number of ratios were used to express this value, but it is now taken as the ratio of the increase in terminal voltage from full load to no load, with constant speed and excitation, to the full load voltage. Regulation is to alternating-current design what commutation is to direct, and many of the elements in both are common. The principal factors which affect regulation are a variation in the useful magnetic flux due to the demagnetizing influence of the armature; a distortion of the magnetic field, due to the cross turns, which changes the form factor of the induced wave of e.m.f., the reactance of the armature winding and the real and apparent resistance of the same. These quantities, with the exception of the armature resistance, vary with the power factor of the load and also, at any given power factor, vary through a cycle. Methods for predetermining the regulation have been developed simultaneously with improved methods for obtaining the same in the design of the machine. It is impossible to test large generators under actual load conditions before they are installed, and some method of calculation from test results is necessary in order to determine if the guarantees in this respect have been met. Also it is extremely important in estimating the conditions of excitation for different load and power factors.

The first method was to run the machine on short circuit and from a determination of the synchronous impedance calculate the fictitious value of the generated e.m.f. which gave the regulation, and, with the saturation curve, determined the exciting power. The next was to consider the magnetomotive forces obtained in this way, and to take the final e.m.f. from the saturation curve. A later refinement has been to separate the effects of self-induction from those of armature reaction, and to use a combination of the above methods. Many other methods have been proposed and discussed.

When used with reference to the particular type of machine, the above methods give more or less accurate results for non-inductive loads; the combined method, if good judgment is used in estimating the reactance, gives fair results for power factor loads as well, but after a large amount of discussion the subject is still in an unsatisfactory state.

The changes in design to secure good regulation have varied with different manufacturers. Some have distributed the winding while partly enclosing the slot, and use low reactions and a nearly straight saturation curve; low reactions bringing small exciting power but large iron sections and producing a heavy machine. Others use open slots with heavier windings on armature and field, a somewhat saturated magnetic circuit, and obtain thereby a lighter machine.

ALTERNATOR ARMATURE WINDINGS.

Early single-phase generators had all coils in series for 2,200 volts and the two halves of the armature in parallel for 1,100 volts. Some early polyphase machines possessed closed windings with taps brought out for the number of phases desired. Many two-phase generators were wound, as is present practice, with two single-phase windings each occupying half of the armature surface.

Three-phase windings are connected either star or delta. With the latter connection care must be taken to see that no pronounced third or ninth harmonics exist, which might cause a circulating current to flow in the short-circuited delta. This has never been found to any marked degree with inductor alternators, and where, in the revolving field type, some current may exist, the design of the machine renders it practically harmless.

As in direct-current generators, alternators may have series or parallel armature connections. The coils may be connected in groups and these groups may be connected in either series or parallel. Naturally a large number of peculiar windings exist, but only the simpler ones have found wide application. The slot contains one or two coils and we have either a barrel or a chain winding.

Increasing outputs, necessitating larger conductors and the use of higher tooth densities, have brought about the use of rectangular stranded cable for armature conductors. This is sometimes used in conjunction with solid bars in the bottom of the slot. Square copper wire was developed for space economy and has had much use for armature windings. For many cases a special rectangular conductor of dimensions determined by the specific design, offers the best solution.

The early machines were wound for 1,100 and 2,200 volts. This was later changed in some installations to about 400 volts. Improvements in insulating materials and the desire to save the cost of step-up transformers have resulted in machines wound for all voltages up to 13,000, which is the highest standard in this country to-day; 6,600 volts are common practice for large installations and 13,000 volts are rapidly becoming so.

The design of alternators for parallel operation has been a recent advance. To provide means for quickly damping any oscillation is the element of success in devices which have been employed on the generator itself. The problem of such operation, while successfully solved, involves much besides the electrical relations. The latest European designs include induction and compensated machines of various types which are still in an experimental stage.

The great change which has taken place in dynamo construction is shown in the accompanying illustrations. Fig. 1 is Faraday's first experimental machine, and Fig. 2 the largest direct-current generator built—the 3,700-kw machine at Boston. Fig. 3 shows a revolving-field type polyphase generator with direct-connected exciter, built in France about 1880, and Fig. 4, a modern engine-driven alternator of 2,000 kw.

Reminiscences of Work on Electrical Patents.

By Edward P. Thompson.

"Whatever the title may be, the subject matter always includes temperance," I once heard remarked about John B. Gough's noted humorous lectures. Similarly, whatever generic title is proposed to me, the specific title must be inventors or inventions. This time it will be both, by way of variety, omitting names, for fear their owners might possibly object.

First, I would like to tell about the narrow escape of a wealthy electrical inventor, who, when not rich, had informed me that he wanted to live in a $50,000 residence. He has since owned two such villas. While rooming with him in the same suite many years ago, I heard moaning and groaning, one night, and I found him only able to say that he was dying, and that, during the day, while experimenting with vacuum pumps, he had swallowed a few drops of mercury, by sucking on the end of a tube, terminating in that metal. "The tube was vertical and forty inches long!" he exclaimed, "and yet I thought mercury would rise only thirty inches, even by full atmospheric pressure." A little mustard cured him. The next day he engaged his patent solicitor to apply for a patent on the conception of a pump operating upon an alleged new principle, which was discovered by his being poisoned nearly to death.

Inventors are often in such a hurry to test an idea that they do not take the necessary time to collect and construct the proper apparatus. Incandescent electric lamp vacuum pumps were all the rage with inventors of a quarter of a century ago. I had occasion to visit one of our five most prominent electrical inventors. On my way to his laboratory I pictured to myself the luxury of the facilities that must certainly surround him. The amount of capital he could call upon was practically unlimited; his record as a great inventor had been long established, and he had been awarded many patents. I found him alone in a barren room ten feet square. The lamp bulb which was being exhausted (?) was suspended by a string from the ceiling. No carpenter had been ordered to construct a shelf to hold an iron reservoir containing about five pounds of mercury. No, the inventor held it up high with one hand while with the other he raised and lowered a tomato can full of that heavy metal. The glass tubes, mostly iron gas pipes—if I may perpetrate an Irish bull—had been patched together at a hundred different points by himself or some other amateur. "Crude, crude, crude," I said to myself. "Just trying to see if the principle is O. K.", he remarked, apologetically, as if he could read my thoughts by my expression.

The generosity of another one of the "Electrical Five" was almost incomprehensible. On one occasion I inquired casually what result would follow from certain technical speculations. "Try it," he replied, instantly. "It is all very well for you to say to experiment, but I have no adequate facilities," I responded. "Use my laboratory," he urged. "A week or more would be required," I answered. "Take as long as you please," he said. For ten alternate days, although a suit of clothes which became saturated with odoriferous red oxide of nitrogen in the chemical room had to be thrown away; although the smell of gas from the Bunsen burners in the glass glowers' department was rather asphyxiating; although not only my hands but my face became black in the tool room, and although the mercury vapor in the pump room was appreciably salivating, yet I was blissful.

Inventors and their backers sometimes appear ludicrous. I remember the sight we once created at an electric brake test, ten years ago, while we were riding through the country for a few hundred miles. The villagers and farmers stared, not only with wide open eyes, but with wide-open mouths, at a train made up of dilapidated and abandoned freight cars, dotted here and there, on top, by men wearing silk hats and frock coats. Contrasted with the freight cars was a new Pullman car in the middle of the train. More dress hats were on the locomotive—or more accurately stated, were on *men* who were on the locomotive. While still staring, the spectators witnessed an emergency stop, and glossy high hats flying through the air by their own momentum. In those days, only when all on board were knocked down, was the brake pronounced highly efficient.

The popular or non-technical mind is more observant in experimenting than we sometimes give it credit for. One day, while making some tests, my father appeared on the scene. I was adjusting the aerial wires and connecting up the wires between the relay, battery, coherer, etc., etc. The wires were long and snarled, and, therefore, were much in evidence. I thought he might be interested to know that all this paraphernalia related to wireless telegraphy, so I mentioned the fact. "Wireless telegraphy!" he exclaimed. "I never saw so many wires in my life."

I congratulate you upon the long and prosperous career of the Electrical World and Engineer. I measure my technical term by its life, for it was in 1874 that I entered Stevens. May many more years of usefulness await you.

The Unknown Nature of Electricity.

By Major John Millis, U.S. Eng. Corps.

To me the most impressive thought connected with the extraordinary advances that have been made in electrical science and in its industrial applications during the past thirty years is that the present state of the science and its related arts has been attained with so little knowledge of the real nature of electrical actions. This suggests the enormous strides in the number of practical applications, in the simplicity and economy of apparatus, and in general efficiency that are yet to be expected in case the mysteries of electricity are ever solved.

As to the progress in this direction during the last thirty years it must be said that it has not been especially encouraging. On the other hand, the newer manifestations of very recent times, or rather the interpretations and theories that have been engendered by certain recently discovered phenomena, seem to me to have befogged the subject rather than to have contributed to its elucidation. It is my belief and expectation that the time is not far distant when the extensive and somewhat confused collection of data regarding electrical as well as all other physical phenomena will be crystalized by a generalization of surprising simplicity. Neither abstract mathematical research nor complex and illogical assumptions regarding the nature of matter will, in my opinion, point the way to the ultimate solution, but the basis for such solution is to be sought in principles that will appeal to the human intellect as simple, practical and consistent. I regard the acceptance of such a general theory for all phenomena of matter as likely to mark the beginning of the next most important period of practical electrical development, and I have not yet seen the announcement of anything that looks to me as likely to indicate directly the development of such a theory.

The Growth and Influence of Electrical Industries.

By C. A. Coffin.

On the occasion of the thirtieth anniversary of your paper, the establishment of which was the genesis of electrical journalism in the United States, it is interesting to review this period, during which the growth of your journal has kept pace with the wonderful development of a great industry. The great ability and candor with which you have ever recorded the achievements and stimulated the activity of all workers in the field of electricity has been a potent force.

In 1874, practically the only commercial piece of electrical apparatus in use was the simple Morse telegraph, followed immediately by the duplex and Edison quadruple instruments. While the arc lamp, the telephone and the incandescent lamp had all made their appearance a few years earlier, it was not until 1886 that the electric railway motor came to be regarded as possessing commercial possibilities. Thus, springing from an experimental laboratory, there have, in twenty-five years, been developed industries which in the last year alone have produced over $150,000,000 in manufactured articles. That this development is still going on with unabated enthusiasm on the part of the engineer, inventor and manufacturer is an ample guarantee of continued growth and of more varied uses of the electric art.

New designs of apparatus and devices, embodying physical phenomena unthought of even four or five years ago, continue to surprise those intimately associated with the industry, no less than they surprise the public. During this evolution there has grown up a class of young engineers, chemists and physicists who form a body of trained minds unique in the world's history. There certainly is no other field of work where the element of scientific knowledge is so influential and essential as in the multifold applications of electricity.

The producers of accessory apparatus and material have been forced to come to the electrical standard. To the electrical engineer is largely due the present excellence of the gas and steam engine and of hydraulic machinery. The maker of iron and steel has better learned his product and has brought it to the present high quality largely through the requirements of the electrician. The present wonderful development of the steam turbine, in whatever form, has been stimulated by electrical requirements, and but for these demands it would be far less advanced than it now is.

It has been your good fortune to record the discoveries and the growth of the industry, and to encourage it vitally these many years. That such a function, so well performed, has been of the highest value, none can question, and I express the sentiment of all who have watched your career, in wishing that your next thirty years may be a witness to and a part of continued progress in the development of the electric art.

Twenty-four Years in the Edison Lamp Factory.

By John W. Howell.

When Mr. Edison concluded that a successful lamp should have an enclosing globe made entirely of glass with all joints fused, the corollary which at once presented itself to his mind was that the lamp must be so durable and so cheap that when it failed it could be thrown away. When the Edison Lamp Company was organized Mr. Edison fixed the price of lamps at 35 cents, knowing that the lamp would cost more than that until suitable manufacturing methods were developed. This development has been going on for twenty-four years, and still there is work for the engineering department of the lamp works.

In this newly-created industry all operations were done by hand by more or less skilled labor. Now machine methods are quite general. The making of carbon filaments and the making and assembling of the glass parts were entirely new operations. No machines existed which could be adapted to the work. The machines had to be originated and developed for this work, and they have been. This statement is nothing like so impressive as is seeing the machines by one who was familiar with the work as previously done by hand.

The exhaustion of lamps by mercury pumps required from four to six hours in 1881. Improvements in pumps and methods reduced this to ½ hour in 1895. Since then by simple piston pump and "chemical exhaust" a much better result is produced in one minute. The cost of exhausting a lamp at the end of 1882 was considerably greater than the total cost of a lamp at the present time.

All the glass working operations have been changed from hand work by "glass blowers" to machine work by unskilled labor. The labor cost of the principal glass operations is now a little more than 10 per cent. of the cost in 1882.

Until 1894 all our filaments were made from bamboo, each piece passing through eight separate hand operations. Now squirted cellulose is used. In this department we now employ 83 operators. If we should go back to our bamboo fibre we would require over 2,150 operators for the same production.

Photometric methods and apparatus have been wonderfully improved and developed. The cost of photometric measurements is now 9 per cent. of the cost in 1882 with a great gain in accuracy.

The lamp of 1880 contained at least 30 times as much platinum as the lamp of the present day. The amount and cost of glass and other materials used have also been greatly reduced.

The greatest production reached in the Menlo Park Lamp Factory in 1882, was 1,000 lamps in a day of 24 hours. The present production of lamps by the General Electric Company is 100,000 lamps a day of ten hours. To produce these requires about 3,800 employees, of whom 80 per cent. are girls.

The lamp of to-day is very much superior in quality to the lamp made in Menlo Park, a great many improvements having been made by careful attention to small details of manufacture, while some very considerable steps in advance have been the results of careful investigations of phenomena observed in the processes of manufacture, and the adoption of new processes or methods.

The lamps made at Menlo Park for the steamship *Columbia* consumed about 100 watts for 16 candles. To-day the standard 16-cp. lamp consumes 50 watts. The useful life of a 50-watt lamp to-day is undoubtedly longer than was the useful life of the 100-watt lamps of 1880, and while we have no data for a correct comparison showing the improvement which has taken place, we can get a good idea of it from the fact that the estimated useful life of a 100-watt, 16-cp. lamp made to-day is over 10,000 hours, which is about as many times the probable useful life of the 1880 lamp as the number of elapsed years.

In the future I believe this multiplier will greatly exceed the number of elapsed years, for I have entire confidence in the fitness of the carbon filament to maintain its place among artificial illuminants.

The Slowness of Storage Battery Evolution.

By Robert McA. Lloyd.

In reviewing the scientific literature of the last twenty years one is impressed with the vast results recorded to the credit of investigators, engineers, manufacturers and energetic business men, but perhaps we may lose sight of the fact that in this period an immense amount of work has been done of which no account exists. Many great researches have been prosecuted for definite purposes which were unproductive of results of commercial value or scientific interest and, therefore, not reported. And many able men have wasted their time and resources in fields that have proven barren or in the study of problems that remain unsolved.

There are other fields in which great efforts have failed to achieve the success hoped for, but where enough has been accomplished to form the basis of commercial operations of some importance. The storage of energy and electrical energy in particular began to attract a great deal of attention about twenty years ago, and a continuous search has since been made for materials in which and methods by which this energy may be accumulated and reserved for future use. Life, reputation and treasure have paid dearly for the development of the storage battery of to-day, about which has grown up a thriving industry in Europe and America; but it can hardly be said that the goal for which electrochemists were striving twenty years ago has yet been reached. Research in storage battery science is slow for the reason that months and years are necessary for many of the experiments. The test of time is also paramount in every application of storage batteries to commercial purposes, and while there is every reason to expect great development in this branch of electrical science and industry during the next twenty years, the rate of progress may still seem slow to the readers of this journal.

I cannot send my congratulations to the Electrical World and Engineer without expressing my warm regard for its personnel, and the hope that the electrical fraternity will continue to have for at least twenty years more the encouragement and comradeship of its present editors.

Fifteen Years of Electric Heating.

By JAS. I. AYER.

MY participation in this work covers a period of a little more than twenty years, beginning at a period when incandescent lamps were little more than toys, and the arc lamp had reached a stage where we could cheerfully assert that the last lamp on the circuit would burn as brightly as the first, no matter how long the circuit; and that it required but two-thirds horse-power per lamp for their operation.

To the confiding investor it was later necessary to explain why a 50-hp engine was fully loaded driving a 40-light dynamo operating 30 lamps, and he was told that the horse-power consumed by the lamp was electrical and not the indicated horse-power of the engine. It was then clear to the lay public that the mysteries of electricity were not to be compared with anything which had come within their ken before.

To-day when we have children entering college who do not remember any other than the incandescent light in their home, the pater stands by watching the electric meter correctly record on the dial exactly the number of lamps that are being operated under his own observation by the innocent electric meter, which has developed such an extraordinary bill. He then realizes that the mystery of electricity is as great as ever.

The remarkable expansion which has taken place, showing practical so many new applications and methods that by wise leaders from time to time were condemned as impossible or impracticable, seems to leave no just ground for any one to predict any limitations of the expansion in the future. It is curious in looking back to find how few of any proposed electrical branches have failed to make good. This to me is the most remarkable element of the history of this wonderful industry. In almost every instance the toys and condemned theories have become important elements of useful application. There is hardly a proposition in the way of a new development that was considered at all seriously that I can recall, except the development of electricity direct from coal, that has not justified itself.

Electric heating attracted attention about fifteen years ago, and first efforts were met with that hearty loyalty characteristic of the public to everything electrical, and its successful development was frequently pronounced on hearsay only as an accomplished fact by the average electrical "expert" in his usual optimistic way when appealed to. He could not afford to admit his ignorance; and it was safer to endorse the claim. All of this resulted in securing favorable consideration for the early elementary products created in a new field, at a time when the demands in the older developments for both men and money, far exceeded the supply. The result of feeble efforts with crudely made products, coupled with the then high cost for current, was a general impression, very firmly established, that electric heating apparatuses for general domestic and factory applications were delicate, expensive toys, which, even if they could be improved and made sufficiently good, were impracticable because of the cost for operation.

This swing of the pendulum was wide, and when the development of the industry was taken up more seriously the debris of this advance guard formed obstacles quite as serious in securing the ear of the public as had to be overcome in preparing a more suitable and logical product to offer them. Electric heating is one of the last of the early developments to "make good," but in the past few years it has made good, and to-day, while it has firmly established itself and gained its place in the line of permanent electrical industries, its broad and extensive development is just about beginning.

While the number of electric heating units in daily service runs into many hundred thousand within the next few years the contrast with results developed to-day will be insignificant. It has been a slow process putting into service thirty or forty thousand flat irons to smooth the way for the work that is to come, but it is something of a triumph to put twenty thousand stoves at work baking as many thousand crackers every five minutes, developing thereby a product that could be produced in no other manner, and yet doing it at a cost that puts it on a par with other methods for turning out such goods.

The complete and elaborate equipment of the large Government Printing Office in Washington for all special heat requirements, and similar work in a great variety of establishments in other lines, are the foundation stones for the beginning of as broad a development in this line as the application of the electric motor if not greater.

Reminiscences of the Universal Exposition of Electricity in Paris, 1881.

BY PROF. HENRY S. CARHART.

The Paris exposition of electricity in 1881 was notable for many things. The first international Electrical Congress was held in connection with it, and this congress stands out in the history of electricity both on account of the eminence of its members and the results of their deliberations. It will be recalled that the theoretical definitions of the ohm and the volt were confirmed by this congress, and that it added the ampere, the coulomb and the farad. These units went into immediate use, and the International Committee charged with the determination of the length of the thread of mercury one square millimetre in cross section and at a temperature of zero degrees Centigrade, which should represent in material form the resistance of the ohm, immediately began its work.

The personnel of the congress, which was composed of official delegates assembled under the auspices of the French Government, was no less notable than the work done. It included many names which stand forth with great prominence in the annals of electricity. There were Clausius, Helmholtz, Hittorf, Kirchhoff, Siemens and Wiedemann, of Germany; Ayrton, Latimer Clark, Crookes, Dewar, Hopkinson, Preece, Rayleigh, Kelvin and Tait, of Great Britain; Becquerel, Cornu, Fizeau, Bouty, Joubert, Lippman, Mascart, Planté and Violle, of France; Rowland, of America, and Ferraris, of Italy. Alas! How many of these have since died.

The Paris Exposition of 1881 was notable also for its exhibits. It was the period of the inauguration of great electrical industries. One recalls first, perhaps, the exhibits in incandescent electric lighting. The Edison "system" was there, of course, "Jumbo" and all. Who had the temerity to predict at that time that in little more than twenty years we should see grow out of this as one of the chief contributing streams the present General Electric Company. When one compares the Edison "Jumbo" generator of the Paris exhibition with the direct-connected generators of the present, of 5,000-kw capacity and upwards, he is impressed with the rapidity of the evolution that has taken place, not only in size, but still more in scientific and technical development.

When the youth of to-day hears of Sir Hiram Maxim and his fame derived from the design and manufacture of rapid firing guns, he is hardly prepared to read that the inventor of the Maxim system of incandescent lighting at the exhibition of 1881 was indeed the original of the present Sir Hiram. He was then a plain aggressive American; he is now a knighted English subject. The year 1881 may be properly described for him as the period when "knighthood was in flower."

In 1881 the storage battery was in its infancy. Faure had just produced a great sensation by sending a storage cell to Sir William Thomson, who had made a rather startling report about it. In the Palais de l'Industrie were the exhibits of both Faure and Planté. Among my recollections of the distinguished men at the exposition none are more delightful than those relating to that charming French gentleman, M. Planté. His memory should ever be kept green as a pioneer scientific worker of exceptional value.

Perhaps the exhibit which one recalls now as "bahnbrechend" above others was the electric railway installed and exhibited by Siemens & Halske. It was indeed only a few hundred feet long, and the connection of the car with the trolley wire was of a very primitive and uncertain kind. The under-running trolley wheel was an invention of a later date; still the exhibit contained the germ of the modern electric railway in the early stages of development.

Such an exhibition has a large value in the dissemination of new ideas. The seeds of invention are there thrown to the winds and are carried to the four corners of the earth. The Paris electrical exhibition was the beginning of the new era, both in the science of electrical measurements and in the technical applications of electricity. We look back to it as the day of small things electrical, but it was in reality the day of large and brilliant ideas.

Past, Present and Future of Electric Traction.

By Frank J. Sprague.

On an anniversary one may become reminiscent. 1874, the year of the birth of the Electrical World and Engineer, has for me a special interest, for although I had set foot on this planet about the date of the laying of the first Atlantic cable, it was then that as a cadet at the United States Naval Academy I began the professional career which ended in the electrical field, when I resigned from the service in 1883 to become one of Mr. Edison's assistants. A prolific period this, and one in which the Electrical World and Engineer has been an effective recorder, tutor and encourager. Of what has been done in many electrical fields others can tell much better than I, so I will speak in brief fashion of but one subject—some features of the development of electric traction.

Although when the Electrical World and Engineer first went to press, a quarter of a century had passed since Farmer and Page had carried on their experiments with small model electric railways, there was not in existence a single car operated by electricity. Five years later Edison had in his development of the incandescent light created the low-resistance dynamo and established the multiple arc system of distribution, but even after eight years more elapsed there were less than a dozen electric railways the world over, scarcely any two alike, and none typical of the modern development, to mark the work in this line of such pioneers as Siemens, Henry, Edison, Van Depoele, Reckensaun, Daft, Field, Bentley, Knight and others. Perhaps the time was not ripe, and it needed a special combination of opportunity and willingness to assume the great commercial risks, as well as a departure in practice profiting by the mistakes of earlier work, to start that industrial progress which has been so astounding. Such an opportunity occurred at St. Joseph, Mo., and more especially at Richmond, Va., in 1887, when, under the auspices of the Sprague Electric Railway & Motor Company, which had been largely fathered by Edward H. Johnson, and adopting a principle of motor construction and suspension tested by me on the New York elevated railroad the year before, the active commercial development of the electric railway began.

The vicissitudes of the Richmond road have passed into history, its apparatus into honored and well-earned rest, but the principles underlying its construction and operation have survived, and to-day mostly dominate all electric traction, for there was used the multiple system of distribution at constant potential of 400 to 500 volts, the single overhead trolley with parallel main conductor and feeders, the ground return with bonded and reinforced rails, the universal movement underrunning trolley carried in the center of the car, double motor equipments under the car, centered on the axles, geared to them and flexibly supported at the free end, fixed brushes for both directions of movement, variation of current and torque by variation of field resistance and turns, dual control of motors, and series and parallel operation. While novel, all these features were not original with Richmond. Edison and others had used constant potential, Van Depoele form of underrunning trolley. I had proposed a rigid overhead conductor with flexible overhead contact for the Metropolitan Railway in London, in 1882; and Reckensaun had put into operation series parallel control; but many features were distinctly new there or in the preliminary experiments of the Sprague Company, and at Richmond there was the combination of various ideas old and new on a scale commensurate to achieve results.

While that work was in progress the Van Depoele Company was offered me by Mr. W. J. Clark, whose commercial sagacity and effective work in the development of electric traction has been so many times exemplified, and on my failure to take it up (I could not) it fell to the Thomson-Houston Company and Mr. Coffin. Aided in a great measure by Van Depoele's happy adoption of the carbon brush, and with unusual business energy, the Thomson-Houston Company rapidly developed. The resulting rivalry and warfare between it and the Sprague Company, although not unattended by some disastrous results, on the whole was of ultimate great benefit to the art because of the rapid development of apparatus and the extension of electric traction. In 1890 came the absorption of the Sprague Company by the Edison General Electric, with which it was allied by financial and manufacturing interests, and later the union of it with the Thomson-Houston in the General Electric Company.

At Richmond, it should be noted, began the contest between the electric railway and the telephone interests because of the common use of earth and rail returns, with resulting injurious effects on the weaker and more delicate apparatus. This was waged in not less than sixteen States of the Union, with the practical result of the adoption of complete metallic circuits for the telephone system—a result the necessity of which was already beginning to be apparent, and which was later emphasized by the growth of long-distance telephone service, quite independent of the influence of electric railways, who were not the sole distributors of peace and—potential.

A decade passed and the trolley hummed its song of victory and emancipation while weaving its threads in every civilized country. Horse, mule, cable and prejudice disappeared, towns became cities, farms became suburbs, homes grew up in the place of tenements, time and money were saved, the health and morale of employees were improved, great works were created, and an army of men were employed. Companies were consolidated into great systems, as under the initiative of Henry W. Whitney on the West End of Boston, and hundreds of millions of capital were invested.

But with it all the trolley remained essentially an individual system, the movement of single cars along highways, picking up and leaving passengers wherever desired, its use largely determined by convenience, capacity and economy under such conditions, save in a few instances of limited train movement where the power was consolidated in a single car at the head of a train, a kind of equipment in fact on which work was progressed as early as 1885. The steam railway field on its own exclusive right of way was practically uninvaded, although as early as 1892-3 the construction of a locomotive for experimental work for Henry Villard had been undertaken by Drs. Louis Duncan, Cary T. Hutchinson and myself; and the General Electric Company had actually undertaken the contract for operating the trains through the Baltimore tunnel. But conditions where electricity could be applied on such a scale were limited.

In 1897, however, just ten years after the Richmond beginning, an opportunity again arose for a development which may also be fairly termed epochal. For a dozen years the Manhattan Elevated Railway Company had been the objective point for electric enthusiasts, and for nearly two years I had endeavored unsuccessfully to get an opportunity to make demonstration there at my own expense of a new system which was the outcome of the electric control of elevators. The proposed equipment of the South Side Road, of Chicago, under the technical advice of Sargent and Lundy, the latter of whom had been with me in the early work, afforded the opportunity I sought, with the result that the multiple-unit system was contracted for, and before the end of the year tested at Schenectady and Chicago.

This system did not consist simply of a method for single control of motors on different cars of a train, for that had been proposed many years before by others as well as myself, but for grouping into a train two or more motor cars, each equipped with motors and controllers for those motors, with provision for simultaneous control from master switches of all the main controllers through the medium of an independent electric train line common to all the cars, and connected on the one hand to the master switches, and on the other to the operative parts of the controllers of several equipped cars. The connections from car to car were made by jumpers, and the main current for each car was taken by collectors on that car. The train connections were such that cars could be made up into any desired aggregation, without regard to number, order or relative relations. As originally planned (and the original equipment is still in operation) the main controller was of the cylinder form, with pilot motor drive. Stepped or automatic advance under current limitation on each controller was obtained by relays operated from the train line. Since then the multiple unit idea has grown and spread until it is now almost universally adopted for all heavy work. Many variations in detail have been made from time to time by different inventors, such as operating the cylinder by air pistons or magnets instead of by a pilot motor, or breaking up the controller into different parts, each operated by a magnet or air piston, with or without automatic control, or with the automatic feature limited to the main switch. But the essential principle—the electric control of the controllers from master switches through an independent line—has never been and is not likely to be, departed from.

From combining and operating car units equipped with motors aggregating a capacity of 100 hp for passenger service only, the practice has now developed until it is applied to locomotive operation.

The 2,200-hp units which are to form a part of the New York Central Railroad equipment will be so operated, giving at times a possible aggregate of nearly 7,000 hp under single control! It is here in New York that two of the greatest improvements are now being carried out which will have a marked, although perhaps specialized influence on electric traction. I refer, of course, to the great work of the Pennsylvania Railroad Company, and the even more extensive electric undertaking of the New York Central—the latter of which is actively pushing, in connection with its terminal changes, the electrical equipment of its regular main and suburban service for nearly 40 miles out from its city terminal, where the heaviest trains will be operated at the maximum speed.

The plans adopted for this equipment, decided on by a commission of which Vice-President Wilgus is chairman, include the use of continuous-current motors within the zone to be equipped, a decision of perhaps more than ordinary moment at a time when world-wide experiments are being undertaken, and extraordinary claims made, in behalf of alternating-current motors; and one which warrants some comment both upon the special subject of such motors and the electric operation of trunk lines in general.

The present is not the time for me to go into any detailed statement of the reasons which were conclusive for the commission's decision, but suffice it to say that I am entirely satisfied with it, and believe it was the only one which could have been safely reached at the present time. This is said without any spirit of antagonism to the alternating-current motor development, and without abating any jot of confidence in, or hope for, its future. Certain statements, however, I think, can now be safely hazarded: One, that the polyphase motor will not secure any lasting foothold in railway operation; another, that the continuous-current motor will not for a long time outlive its usefulness; and finally, that trunk line electric operation as such is not of the immediate future.

Machine for machine, the commutatorless motor, coupled with the ability to economically transmit electricity at high pressure for a great distance and transform with stationary apparatus to any desired pressure, has been matched against the limitations of the commutated motor and restricted distribution for the 15 years since Ferraris and Tesla first advocated its use. Polyphase transmission has become a most influential factor in long-distance transmission, and the polyphase motor finds a wide and increasing field of usefulness; but the continuous-current motor still performs its service placidly and demonstrates its utility, while throughout the United States there is not a single polyphase railway, and in Europe there are but a few introduced, chiefly by a single company of great technical ability.

Within the past year, however, undoubtedly spurred on by Mr. Bion J. Arnold's predictions and pioneer work, the leading companies in this country have made material progress in the construction of single-phase alternating-current motors, and similar developments are taking place abroad. Probably in no phase of the electrical development has there been greater concentration of high technical skill and mathematical ability than in this new departure by such men as Steinmetz, Lamme, Finzi and others. The methods and results vary materially, but one significant fact is patent in all—the much-despised commutator has reappeared, and under conditions some not as favorable as exist in the continuous-current motor.

In all alternating-current motors there must be a reduction of armature potential if high-potential transmission on the trolley exists, either by short-circuiting a closed armature with independent circuits in a field supplied direct by high potential, as in Prof. Elihu Thomson's repulsion motor, or by transformation of the whole or part of the current energy, as in the Lamme and other motors. In some cases even a greater number of brushes is used than in continuous-current practice. At present the latter type of motor apparently has some advantage in the matter of weight, individual efficiency and freedom from sparking, and I think will maintain it. Undoubtedly, however, the future holds out much promise for the single-phase motor, and it will be a satisfactory machine. It is well, however, to ask wherein lies the demand for it, and why does it threaten the supremacy of its rival? There are two special reasons remaining, that one on which much stress was laid, the absence of commutator, no longer existing. These are the possibilities of use of a fairly high potential on the trolley, or secondary system of distribution, with resultant increase of distance between the substations and better averaging of load on them, both very important features, and the abolition of the rotary converter, a desirable result. But as to the first there is a chance for error of judgment, for the possibilities of the direct-current motor are by no means exhausted, and for any given maximum potential and track rails specific resistance continuous current admits of the less size of conductor.

In the matter of initial transmission to sub-stations, the advantages of high potential are common to any system of motors. At these points the pressure must be transformed down, the energy being then delivered through rotaries or motor-dynamo sets for continuous current or direct for alternating current to the seconday supply system.

Up to the present it has been the general practice to limit direct-current work to about 600 volts partly for construction reasons and partly because of the existing practice on city systems, or at terminals, where the alternating current is used at 3,000 volts. It would appear at first sight that with the same size of conductors and loss increase of pressure would mean an even greater increase of distance between sub-stations. Since, however, the load on the secondary circuit would increase about as the distance between the sub-stations, and the capacity of the secondary circuit would probably be considerably less than that of the ordinary third rail because of the necessity of carrying smaller conductors over the cars, even if such conductors are reinforced, as would be most advisable, by a main conductor extending along the tracks and supplying the trolley wires parallel to it, the distance between the sub-stations would be materially reduced, and in fact would generally be considerably less than that represented by the simple ratio of the increase of potential.

While direct-current motors may be always somewhat at a disadvantage in the matter of individual potential, when there is a plurality of motors, as in a large locomotive, it is quite possible on a direct-current system to work up to 1,700 or even to 2,000 volts on a single trolley line, maintaining a maximum as in regular use on the Berlin Elevated of from 850 to 1,000 on individual motors; and if a three-wire system be used it is quite possible to make use of a maximum transmission potential of nearly 4,000 volts. I am not prepared to say yet that this is advisable, but it is possible and I submit that in the problems involved in any trunk line development there are many questions of greater importance than that of the relative allowable trolley potentials for direct and alternating-current equipments.

The very essence of successful electric railway operation has been to supply from a single source of power a large number of moderate powered and well-distributed units. Trunk line service is of quite a contrary character, and many of its present features must be changed, or its density of traffic greatly increased before investment necessary for electric operation can be generally considered. It may be accepted as a cardinal principle that no large railway system will generally adopt electricity as a motor power unless it be dictated by the assurance of less cost of operation or a greater return on existing and new investment, and such adoption will not take place until the average density of traffic will warrant the operation on a section measured by the practical limits of transmission from a single station, at which time the joining together of sections will become possible. Infrequent and spasmodic service in large units over long distance offers little chance for electric operation. The early application to the large locomotive units will be in such zones of electrical operation, like the New York Central, where the pressing use of electric suburban service and other special requirements, exist, under which cases all equipments should be electrically operated. Such cases are, however, specific, and are not necessarily favorably conclusive on the larger distance proposition. On this subject I see no reason to change my views as expressed at length many times during the past fifteen years.

Flat Wheels.

The New York State Railroad Commission has recently reported on its work with regard to improving transportation facilities in Manhattan and Brooklyn Boroughs. The operation of cars with flat wheels causing annoyance to residents by the noise has been taken up with the various companies and a more thorough inspection and removal of flat wheels has been ordered by the Board. During the quarter ending November 30, 1,367 pairs of new wheels were placed under the electric cars of the Interurban Company. During the same period 1,659 wheels were placed under the cars of the Brooklyn Rapid Transit Company.

The Dissappearance of Overhead Wires.

By W. Maver, Jr.

While it is true that electrical subways for the use of high and low-tension cables were in use in Chicago, Philadelphia and elsewhere on a comparatively small scale before their employment was begun in New York City, nevertheless it was in the last-named place that the problem as to whether it was feasible to operate high-tension circuits commercially, and on a large scale in cities was to be solved. That this was considered a problem by many at the time in question, 1886 to 1890, will be evident from the fact that some of the men then most prominent in scientific circles were willing to place themselves on record as being of the opinion that it would not be possible to operate such circuits underground. If, said one of those men in a portion of his argument, the conductors are lead-covered to enable the insulation to withstand the destructive influences of moisture and gases present in these conduits, the trouble is only mitigated, for the lead covering is itself subject to corrosion by the same agencies of moisture and gas. As soon as by these means, or by such abrasion as is liable when the lead-covered cable is being drawn into the conduit, or by a defect in the manufacture, the lead pipe is punctured, moisture will soon exert its injurious effect upon the insulation. Besides, with current of high electromotive force there is always present an action of polarization of the insulating material which tends to change its structure and cause the formation of faults in it, which, with other things, would make the difficulties of operation insuperable.

Some of the high-tension companies were at the time willing to place their circuits underground, others professed to be willing to do so, but insisted that the civic authorities should, by actual tests, first show that it was practicable to operate high-tension circuits underground, claiming that the attempts in this direction in other cities had resulted in failure.

The rules that were promulgated for the operation of the high-tension cables in the city were also objected to vigorously by the dissentient companies, especially the rule requiring that the cables should be shown to possess an initial insulation resistance of 15 megohms per mile, per 100 volts e.m.f., it being asserted that this could not be obtained in practice and, if it could be, it would be impracticable to make the tests to demonstrate the fact. 'Said the same authority, the measurement of 100 megohms with the apparatus ordinarily used for the measurement of resistances is a very difficult operation and requires not only a very high degree of skill and the most sensitive and finely adjusted instruments, but it is essential for even tolerable accuracy that the instruments should be free from all disturbing influences and used under conditions which are rarely formed outside of the best equipped physical laboratories.

So far as the making of the necessary tests is concerned, the present writer may modestly say, inasmuch as he either made or supervised the thousands of tests of the cables that were laid in New York subways for a number of years thereafter, that it presented no great difficulty. It may be noted, however, that at the time in question and as showing the dearth of practical electricians then existing, that Mr. G. A. Hamilton, Mr. D. W. Jones and the writer were perhaps the only available experts in New York City for this class of work. The fact that such was the case may be credited when it is stated that the writer was engaged jointly by the cable manufacturer, the purchaser of the cable, and the subway company, to test for them the first high-tension cable that was laid in these subways.

There was at the time under consideration no exact data relative to many of the conditions to be met with in actual practice. Thus the thickness of insulating wall necessary for high-tension cables was not definitely known, and hence some of the first cables manufactured were deficient in this respect, the mechanical strength being insufficient to meet the strains of hauling in, bending, etc., to which the cables were subjected in practice. The writer was fortunate enough to specify in one instance a thickness of insulating wall of .25 in. for a cable designed for 7,000 to 10,000 volts, a thickness which subsequent experience has shown to be ample. The proper size of manholes, handholes, etc., was also an unknown quantity and as a rule they were in numerous cases made too small, a defect which has been remedied in later years. A few months' experience, however, sufficed to throw much light upon all of these questions, and as fast as possible improvements were suggested looking to the betterment of the service. Among these was the use of beveled edges at the entrance of the ducts in manholes to prevent the cutting of cables; the placing of switches on posts or on walls outside of the subways to which switches the cables should be led for purposes of testing, changing circuits, etc., which plan was adopted in the case of the fire department cables and some of the electric light companies, and might be extended further to advantage.

Reverting to the rules relative to the testing of cables, it is but fair to add that these rules were probably drawn purposely rigid as a precaution against the dangers of explosions in the subways. It was a more or less open secret at the time that the opposing interests would subject the cables to the severest tests to demonstrate the accuracy of their contention as to the impracticability of high-tension underground systems, and obviously counter precautions were taken by those financially and otherwise interested in the success of the subways; and to-day no one questions the wisdom of that course.

Early Automobiling Reminiscences.

By Oberlin Smith.

My chief experience in electrical matters (since spending much time when a boy in manufacturing a variety of what was then called electrical apparatus, for my own amusement) has been in the line of motor-driving of machines, especially power presses. As some of the readers of the Electrical World and Engineer may have noticed, I have for several years been an earnest preacher, in the various engineering societies and elsewhere, upon the subject of individual driving. This system, as opposed to the mere coupling of motors to long lines of shafting, or to group-driving, so-called, has passed the successive eras of crankiness and of doubtfulness, and has, mostly within the last two or three years, established itself as the paramount system of the future. Its advantages are too numerous to be repeated in this article, but I venture to predict that very few of the first-class newly-built machine shops of five or ten years hence will contain much, if any, shafting and belting.

Passing over the tremendous and obvious developments which are bound to occur in the near future in electric lighting, power transmission, high-speed railroading, etc., and also the glorious development which many of us see with prophetic eye in the not too far off future regarding the transmutation of heat into electricity, a nearby and very practical line of development lies in the improvement of the storage battery. This will vitally affect the running of automobiles and small pleasure boats, most of which are now run by their owners and chauffeurs under conditions of martyrdom, tempered by a spirit of self-sacrificing cheerfulness, which it is difficult for their friends to appreciate. When a mere layman in this motoring amusement, or art, or whatever it may be called, contemplates the tangled mass of tanks, and cylinders, and pipes, and rods, and screws, and what not, together with the tool outfit for adjustment and repairs, he can but sigh for the time when the electric carriage and boat will prevail, at any rate for purposes of business and pleasure.

To bring about such halcyon days of pleasure travel but two important new conditions are necessary. The first is to have a cheap, light and durable storage battery. The second will consist in the establishment of a system of electric charging stations at proper intervals, upon all our streets, roads and waterways which are suitable for the kind of travel we are considering.

It goes without saying that, upon the whole, we must have throughout our country a tremendous and radical improvement in the quality of country roads. This, however, is sure to come as the use of automobiles increases. It has been already developed somewhat by reason of the invention of the bicycle. Such charging stations should be regulated in some way by state or national law, in connection with the control of highways and waterways, to prevent extortionate prices; and thus will be enhanced the volume of travel and the development of the quantity and quality of the vehicles used therefor.

New Jersey's greatest inventor has taken up the first problem mentioned, with already a considerable measure of success. This it is hoped by all of us will soon ripen to complete fruition. We Jerseymen further hope that a State which has so large a field of travel, and which has already made such progress in good roads construction, will be one of the first to establish the charging stations in question.

While speaking of New Jersey (remembering the editor's invitation for reminiscences) I am reminded that I myself may have aided the progress of automobiling by showing how *not* to do it, I being perhaps one of the earliest chauffeurs in the State, or at any rate in the southern section thereof.

Upon a certain occasion over forty years ago I entered into an autoing collaboration with another boy, who is now a distinguished professor of mathematics, both being fired with enthusiasm to emulate the recorded performances of the occasional steam carriages appearing in England from Sir Isaac Newton's time into and through the eighteenth century.

Instead of building such a vehicle entire, the boys procured a farm engine of about 5 hp built in the general style of a steam fire engine, that is, with a vertical boiler at the rear, fired from behind, and a horizontal engine lying upon the framework in front. They soon realized the difficulty of steering by swinging the front axle with sufficient power and delicacy should either wheel strike an obstruction. This they overcame somewhat ingeniously by fastening ropes near each end of the axle, which came upward and rearward to the main shaft of the engine, being wrapped loosely two or three times around the same, on the principle of a "snubbing post." These ropes continued upward to the hands of the steersman, and with them he could control the axle perfectly by tightening one or the other more or less, the power to hold it against obstacles at either wheel being, of course, supplied by the engine as a rope tightened upon and grasped the shaft thereof.

Upon the first trial one of the rear wheels was connected with the engine by a wide belt running from a small pulley on the end of its shaft to a very large one bolted to the spokes of the wheel, which thus served as the only "driver."

In their haste to get the machine under way they waited not for good weather, but started upon a rainy day with the ground covered with slush. The belt soon got wet and the "auto" was held up for repairs.

For the next trial a chain and sprockets (not easily procurable in those days) were substituted for belt and pulleys. The machine itself ran well in spite of having only one driver, but, time still being precious in the eyes of the adventurers, the next start was made over a very bad road covered with snow two or three inches deep. This road was narrow and crooked, soon reaching a narrow wooden bridge spanning an icy river, then running up a hill at a moderate grade. To avoid delay, no connection was made at this first trial from the throttle valve (an ordinary 1¼-in. steam cock) at the rear of the boiler to the driver's seat in front, where he might have attended to it had not both hands been busy with the steering ropes, and both feet with bracing himself to keep him in his seat.

The professor was kindly allowed the honor of the first trial and when duly mounted yelled to the small boy who acted as fireman (standing upon the ground) to turn on steam, which then stood at high pressure. Being both obedient and strenuous, this youngster revolved the cock handle suddenly through an arc of some 90°, then letting it slip off and fall hidden in the snow as the machine bounded forward and left him standing in amazement at the ambition thereof.

Your servant, who was acting as general traffic manager, rushed into the shop ("garage" should it not have been termed?) wildly searching for a monkey-wrench and triumphantly emerging in chase of the lost auto car, which the powerless chauffeur had by that time succeeded in steering at full speed around the turns of the road and between the railings of the bridge—rather than down a steep bank into the river below. As he reached the hill beyond, with the car ascending and the steam pressure descending, the monkey-wrench and the boy he left behind him succeeded in reaching the steam-cock, and everything ended happily.

The machine not afterwards proving comfortable enough for a touring car was classed in the grade of runabouts, in view of the performances it had performed. Later on it became a stayabout.

Street Crossing Signal.

Mr. C. L. Cole, U. S. Consul-General, Dresden, says: "I notice the trial of a new safety device at street-car crossings in this city, which may be described as follows: A box 2 ft. long and 1 ft. wide is suspended from the wires at the center of the crossing, and at a certain distance the approaching car automatically turns on the current and from the opposite sides of the box is shown in red letters the word 'Halt,' to warn the car coming at right angle as well as teamsters and pedestrians. When the car reaches the center of the crossing, the light is extinguished. Watchmen are placed at all crossings in this city where cars meet, but I am told this device is being tested with a view of avoiding the expense."

A Historical Sketch of International Electrical Congressess.

BY DR. A. E. KENNELLY.

THE history of electrical congresses dates from the year 1861, and the development of the power of such congresses, together with their relation to scientific and industrial activities, is a story of great interest. The electric literature of 1860 shows that telegraphy was then the only industrial application of electricity outside of electroplating. As a branch of physics, however, the theory of electricity was well developed, and nearly all of the fundamental laws were well known, as, for example, Ohm's law, the laws of electromagnetic induction and the laws of electrostatic induction. The practical application of those laws was, however, in a most backward condition. There were galvanometers, batteries and resistance coils, but their calibration was very crude.

The British Association for the Advancement of Science, appointed a committee in 1861, on Lord Kelvin's motion, to report upon the best unit of electric resistance. This committee of a few eminent physicists formed the first electrical congress.

In the following year the committee reported to the Association in favor of Weber's absolute metric system of electromagnetic units. An attempt was made to base the system on the British foot and grain, but fortunately the centimeter and gramme prevailed. Since 1862 all electrical units have been metric units.

The British Association continued its work for several years and the results were finally published in 1875. The committee not only established the C.G.S. system, but also created its half-brother, the practical system, of the quadrant and eleventhet-gramme variety. It determined the value of resistance coils in ohms and of current strengths in amperes. Its ohm, called the B.A. ohm, was 1⅓ per cent. short of the correct resistance, as more recently determined and adopted. It issued copies of the B.A. ohm and B.A. microfarad. It did most valuable service and laid the basis of all subsequent international work.

In the meantime the electric telephone and the electric light came into existence. These new industries greatly extended the needs of electric units, and electric measuring apparatus of an industrial type.

France, since her first Paris Exposition of 1855, has given evidence, like the sun, of an eleven-year cycle of expositions. They have succeeded each other in 1867, 1878, 1889 and 1900. Whether there is any deep sociological connection between these recurrences, and the eleven-year periods of sunspot activities, we leave as a curiosity to the curious. But in 1881 Paris gave a special international electric exposition, as a *hors d'œuvre*. At this exposition an international electrical congress was first convoked. The congress adopted seven articles of faith. The C.G.S. system and its half-brother, the ohm-volt-ampere-coulomb and farad system were adopted. An international commission was charged with a redetermination of the ohm, for practical purposes.

The international commission was convoked in pursuance of this resolution in 1882, and again in 1884. At the latter conference the "legal" ohm was adopted and defined as the resistance of a column of mercury 106 cm. long and 1 sq. mm. in cross-section, at the temperature of melting ice. This legal ohm was about 1 per cent. larger than the B.A. ohm, and about one-quarter of 1 per cent. shorter than the present generally accepted value. The volt was defined in terms of the legal ohm and of the ampere.

The second international congress was held at the next Paris International Exposition of 1889. There were three sections, the first devoted to units, the second to industrial applications and the third to electric signaling, comprising telegraphy, telephony and signals. The first section adopted the joule, watt and bougie-decimale. The second section the quadrant and various definitions in alternating-current technology, namely, definitions of period, frequency, mean and effective current strengths, effective e.m.f. and apparent resistance. The third section considered no units.

The third International Electrical Congress was held in connection with the Chicago World's Fair of 1893. At this congress, for the first time, papers were read and discussed on various subjects in theoretical and applied electricity, apart from the work of the chamber of delegates appointed by the various governments to consider and vote upon units and other matters of international importance.

At this congress there were 144 enrolled members, about 125 of whom were Americans. Some 500 persons attended the opening ceremonies. The proceedings of the congress were published by the American Institute of Electrical Engineers. The chamber of delegates adopted the international ohm of 106.3 cm. of mercury, as an amendment upon the legal ohm of 106 cm. in 1884, which was an amendment upon the B.A. ohm of 104.8 cm., in 1875. The various other international units were adopted to match the international ohm. The international volt was defined in terms of the ohm and ampere fundamentally, but also collaterally as a fraction of the e.m.f. of a standard Clark cell, the specifications for the preparation of which were left to a committee. The committee has not reported. The international ampere was defined in terms of the rate of deposition in a standard silver voltameter. A table of international notation was accepted and printed as an appendix.

Two unofficial international electrical congresses were held at Frankfort and Geneva, in 1891 and 1896, respectively. No official government delegates were appointed to either.

There were three sections in the Chicago congress, Section A for theory, Section B for intermediate subjects and Section C for practice. Thirty papers were presented and discussed. The proceedings of the congress form an octavo volume of 488 pages. No provisions were made in advance for the preservation of this literature and it would probably have been lost if the American Institute of Electrical Engineers had not assumed the task of rescuing it and financial risk of its publication.

The fourth International Electrical Congress was held in Paris in 1900. Like all its predecessors, it was held in connection with an international exhibition. The French Minister of Commerce authorized the movement, which was originated by the Société Internationale des Électriciens. The organization of the congress was first established eighteen months in advance of the sessions and circulars were addressed to very many persons interested in electricity, inviting their adhesion. The total number of congress members enrolled was about 933, of whom about half were French and only a very few were Americans. There were five sections, with several sub-sections, in addition to a chamber of government delegates. About 120 papers or communications were presented and discussed. The only work accomplished by the congress in regard to international units was the christening of the C.G.S. units of magnetic flux and flux density under the titles of "maxwell" and "gauss," respectively. The proceedings of the congress were published in two octavo volumes of 526 and 318 pages, respectively.

The forthcoming International Electrical Congress of September, 1904, at St. Louis, was originated by the St. Louis Exposition, at the suggestion of a number of members of the American Institute of Electrical Engineers. A committee of organization was formed about fourteen months in advance of the sessions. About 5,200 invitations to join the congress have already been issued to persons interested in electricity. Over 1,000 acceptances of membership have already been received and the number is steadily increasing. Invitations have also been extended by the State Department at Washington to the various foreign governments asking them to appoint official delegates, as in the case of the two last congresses, in Chicago and in Paris. Invitations have also been sent to a considerable number of well-known electrical workers all over the world, asking for special authoritative papers to be read before the congress. About 120 papers have already been promised, in response to these invitations. No papers are to be read except by invitation, and the maximum number to be read has been set at 150, so that instead of having to press for papers the difficulty will apparently be to prevent the generosity of authors from exceeding the number of papers set by publication limits.

A feature of the St. Louis Congress, which has never before appeared, will be the official participation of societies and institutions interested either in the science of electricity or in its applications. The American Institute of Electrical Engineers has already adopted a plan of co-operation by holding a convention at St. Louis contemporaneously with the congress, and holding joint meetings with various congress sections, of which there are eight in all. By this means the papers in the joint sessions read on behalf of the Institute are to be printed in the congress proceedings, as being presented by the Institute, while the transactions during such joint sessions will be placed at the disposition of the Institute for incorporation in its own proceedings. It is expected that similar co-operation may be looked for from various other American and foreign societies, the purpose of the committee of congress organization being to enlist the aid and sympathy of electrical workers all over the world, not merely as individuals, but also as societies, the societies lending their influence to promote the success of the congress, and freely receiving a part of the congress transactions, as officially their own, to incorporate, if desired.

There seems every reason to hope for the success of the fifth International Electrical Congress in connection with the St. Louis International Exposition. The number and character of the papers promised, the number of the congress members and the efforts which all connected with the movement are freely contributing towards the enterprise, augur well for the result. The success of such a movement redounds to the credit, not only of the country in which the Exposition and Congress are held, but also to the benefit of electrical science and electrical industry all the world over.

The first electrical congress was made up of a handful of leading scientists of one country. Gradually the movement spread and broadened until an International Electrical Congress came to include scientists from all civilized countries. Now an International Electrical Congress means a carefully prepared organization in advance, a large membership, including not merely electrical scientists, but also very many who may only be interested in some industrial application of electricity. It means, moreover, the collection of theoretical and practical ideas from many sources and different countries, all uniting in a common cause, the increase of knowledge in the science, and the increase in the extent and usefulness of the science's universal applications.

The Ward Leonard Single-Phase Locomotive.

By G. T. Hanchett.

THE development of heavy electric railroading has brought to commercial usefulness a number of devices which have heretofore been of academic interest only. The series alternating-current motor and the repulsion motor belong distinctly to this class,

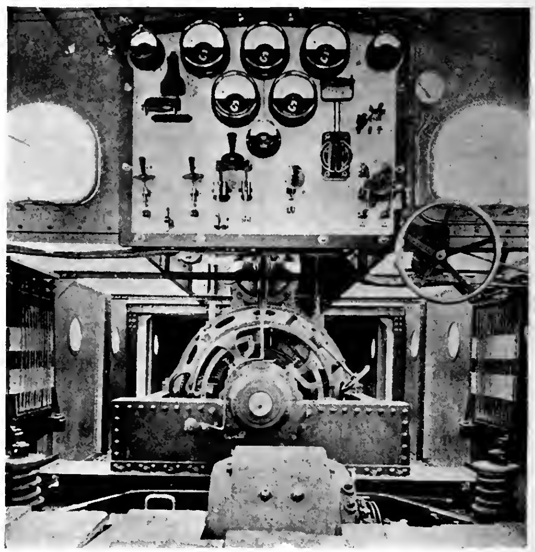

FIG. 1.—CONTROLLER CAB.

and it now seems that the Ward Leonard system of single-phase locomotion will develop into an apparatus of serious importance and consideration in large electric railway work.

To the superficial observer the Ward Leonard system seems to be a mass of unnecessary complication. It was brought before the public by Mr. Leonard in 1891, and briefly described, employs on the locomotive a synchronous or induction motor taking current from a single-phase system, and driving a direct-current dynamo which in turn drives direct-current traction motors suitably geared to the axle of the car. A superficial glance at the device does not impress the engineer favorably. He sees in such an apparatus a rotary system of energy transformation which is a bugbear that he has studiously striven to avoid; and indeed when electric railroading was confined to the propulsion of 8 to 10 ton cars over the streets of our cities, that the time was not ripe for such a radical change for the application of electricity to traction.

It must now be remembered that the requirements of a traction system are now very much different from those that were all-sufficient some ten years ago. At that time the only consideration seemed to be a simple rugged reliable system which would make the wheels revolve. Now much more is needed, and it will be briefly rehearsed in the following paragraphs.

The modern system of electric traction requires: First—Reliability. Second—Economy. Third—A very specific and satisfactory curve of acceleration. Fourth—A system of control which is thoroughly reliable and free from detrimental effects of heavy arcs. Fifth—Simple adaptation to the multiple unit system of traction. Sixth—Ready adaptation to the use of electric power of any variety.

In the old days when it was customary to compare a simple pair of controllers and motors carrying moderately light currents, with the same equipment plus the additional apparatus required by this system, the situation was such that engineers were not inclined to be enthusiastic over the new plan, but now when we have to compare the Ward Leonard motor and dynamo with the complicated multiple unit arrangement, switching large currents, or with a system of transformers and voltage regulators, which are the modern alternatives, to obtain the results that can be obtained with the Ward Leonard system, the latter certainly merits some consideration.

This system as now employed at the Oerlikon Works in Switzerland, where it is undergoing a rigid test, consists of an induction motor adapted to receive and transform single-phase currents into mechanical power. This is transmitted to a dynamo of appropriate capacity by direct connection, and thence the current is distributed to the motors by means of the Ward Leonard control. To refresh the memory of those who are not familiar with this well-known system, it may be stated that in controlling a motor for variable speeds by the Ward Leonard system, the motor is given constant field and the voltage is varied by varying the field on the generating dynamo from zero to a maximum, and also in a reverse direction. Therefore the motors are permanently connected to the dynamo terminals, and there is no opening of the main motor circuit. Those who have had to do with the opening and closing of heavy traction circuits will appreciate that in this way an enormous difficulty is practically eliminated. The burning and melting together of controller and contactor contacts has in these days of great power become indeed a formidable difficulty, and this system, in which the only circuits which are manipulated are those of the field magnet carrying only a few amperes at moderate voltage, it is easily seen is free from this difficulty.

In the second place, the Ward Leonard system supplies its power to the motors without the interposition of rheostats, and it may be safely stated that the efficiency of such a system is undoubtedly superior to the system of rheostatic control even when reinforced by a series-parallel system. Therefore in point of economy of the car equipment itself, there are advantages in favor of the system, and furthermore it is capable of returning power to the line not at a critical speed but at any and all speeds, thereby providing an electric brake of most economical type. In all other traction systems, with the exception of a few which have not been particularly practicable, all the power employed in getting the current of the car under headway is subsequently wasted in heat at the brake shoes. In the Ward Leonard system, however, the accumulated energy of the car is transformed into electricity and fed back into the line, and moreover the system of braking is ideal. It is well known by traction engineers that the proper method of braking is to apply just sufficient braking power to prevent the wheels from skidding on the track. A system whereby power is returned to the line does this automatically, for the moment that the wheels cease to turn, braking effort ceases also, so that by the simple device of weakening the dynamo field on the Ward Leonard system to such a point that the back electromotive force exceeds that of the dynamo, a very effective brake is produced and the energy of acceleration is returned to the line.

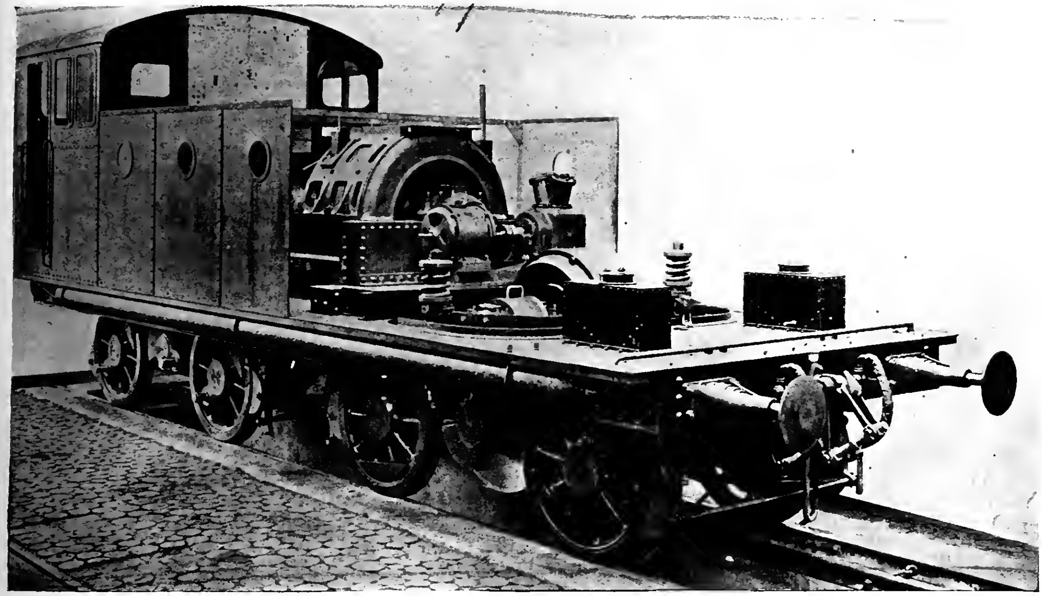

FIG. 2.—GENERAL VIEW OF LOCOMOTIVE.

It may further be noted to the advantage of this system that the acceleration curve is practically under absolute control. An ideal acceleration curve is that which applies power to the motors in just sufficient measure to prevent the wheels from skidding. With motors in series, this skidding of wheels is a very objectionable feature, for one motor having begun to skid, its wheels absorb practically all the power for that purpose, leaving the other almost if not quite at rest, the only alternative being to shut off the power until the wheels get a fresh grip. With the Leonard system, all the motors are in multiple, and this defect is abolished. In applying the power, it is only necessary to strengthen the fields of the dynamo almost up to the point of skidding. If any of the wheels should skid, it is only necessary to drop back a notch or two to reach the result desired.

A further feature of this system of control is the fact that the power taken from the line is directly proportional to the power used at the car and is not proportional to the amperes that happen to be flowing at the time in the motor. The motors may be carrying their full current and exerting their maximum torque, and at the same time only a small amount of power is required from the line for this purpose. With the ordinary system it is impossible to give the motor full torque unless the full power of the motor is taken from the line, which is thereby divided into two portions, a small portion going to the motor and the balance being absorbed in C^2R losses in the rheostats. This greatly simplifies power house design and management by wiping out the element of large starting current and heavy sudden loads.

Not the least of the advantages of the system are the ease with which it can be converted to the multiple unit plan. No bus train wires are necessary; in fact, the number of train wires can be reduced to a minimum of three light wires which supply the fields of the various dynamos on the equipments, and carry a few amperes only. A single rheostat and exciter provide means for raising these wires to any potential desired. The fields of all the dynamos come up uniformly, and with them the voltage of the traction motors. Consequently their speeds increase uniformly.

We are now able to prepare two interesting columns showing the advantages and disadvantages of the Ward Leonard system versus the ordinary heavy system of multiple unit direct-current traction. In this table all of the particulars which are common to both systems are omitted and the auxiliary apparatus of each is listed:

WARD LEONARD SYSTEM.	ORDINARY MULTIPLE UNIT SYSTEM.
Dynamo, motor and exciter.	Not less than 13 and usually more than 20 automatic contacts.
A simple system of low voltage wiring.	A complicated system of series parallel wiring and auxiliary contractor wires.
Acceleration under absolute control.	An acceleration curve seriously limited by the inherent qualities of the apparatus.
Minimum current from the power house when maximum starting torque is required.	Maximum current from power house when maximum starting torque is required.
Rheostatic control involving a rheostat waste of only a few watts at very light current.	Rheostat control wasting very large quantities of power at heavy currents and high voltage.
Return of power to the line and automatic braking.	No return of power to the line under any circumstances and no automatic braking.
The employment of any kind of power desired by the proper design of the receiving motor.	Complete re-design of the entire equipment necessary to use any one kind of power.
Weight in excess of that of the traction motor 100 per cent.	Weight in excess of the traction motor 25 per cent.

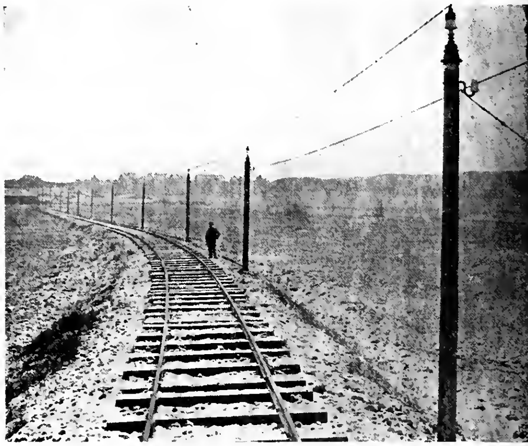

FIG. 4.—VIEW ALONG THE LINE.

A careful system of figuring, Mr. Leonard claims, will show that the added losses of the ordinary series-parallel rheostatic system of control will produce sufficient kilowatt-hours to more than carry the extra weight involved in his system, leaving a surplus for useful purposes.

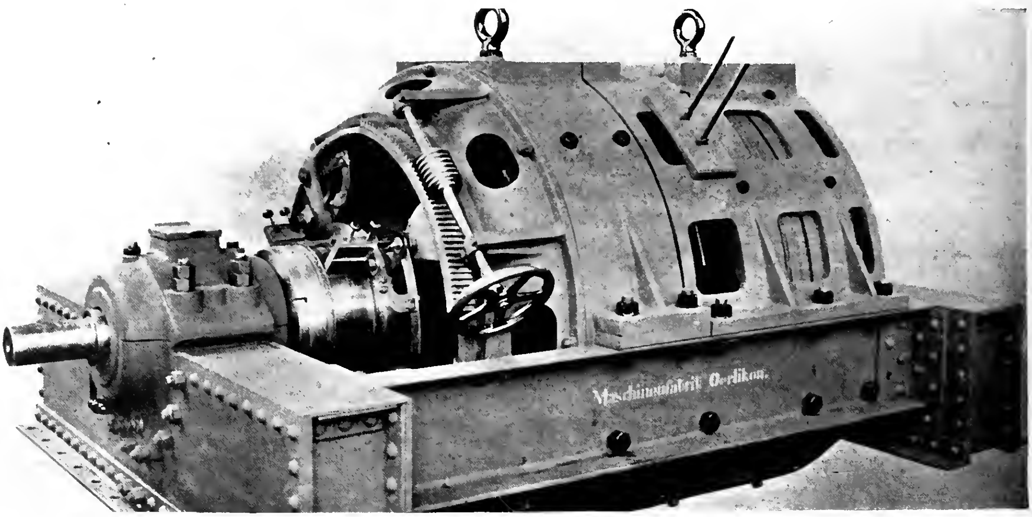

FIG. 3.—THE MOTOR-GENERATOR.

These figures of comparison seem to justify the careful consideration of the traction engineer, and in fact that the system is now being tried in the Oerlikon Works in Switzerland seem to prove that this is being done.

In a paper read on the subject of electric traction on railways, before the Institute of Civil Engineers on February 18, 1902, Mr. W. M. Mordey, whose judgment on such matters is notably sound, made numerous statements which seem very pertinent in this connection. To quote them in toto is beyond the scope of this article, but a few selections may not be out of place. He says: "There need be no irregularities of control of speed, such as are caused by the notches in an ordinary series parallel controller. A perfectly smooth transition can be obtained through the whole range, from large torque at starting and at low speeds, through all the variations of speed, to large power returned at stopping or braking. One further important point in this system is that it makes a much lower maximum demand than either the direct-current or composite system. It has already been pointed out that in the latter system (and the same is true of the three-phase system), the maximum demand occurs at the moment of starting, when the least power is being developed in the train. The output of the generating station and the losses in transmission, in transformation, and in wasteful resistance are then all greatest. Two-thirds of the power produced is lost in resistance. The one-phase system with its variable ratio gear saves all this, or a large part of it."

He further states that large starting torque of the single phase motors is not necessary in this system. Even if they should be so improved as to have a starting torque equal to that of direct current motors, it is likely that a variable ratio process would still be worth using, especially on lines with frequent stoppages. He closes by saying that sufficient has been said to show that the system possesses great flexibility, and offers at least a practicable solution of the problem of a comprehensive general system of electric traction for railways.

Mr. P. E. Huber, before the Zurich Association of Engineers and Architects, has set forth the advantages of the Ward Leonard system, and he gives some very interesting figures with reference to weights. He puts the weight of the locomotive at 44 tons, and states that a three-phase locomotive of equal power would weigh only about 30 tons. He holds that this advantage of weight is more than offset by the difficulties arising in connection with the trolley wires of a three-phase system. Mr. Huber's paper was read February 18, 1902.

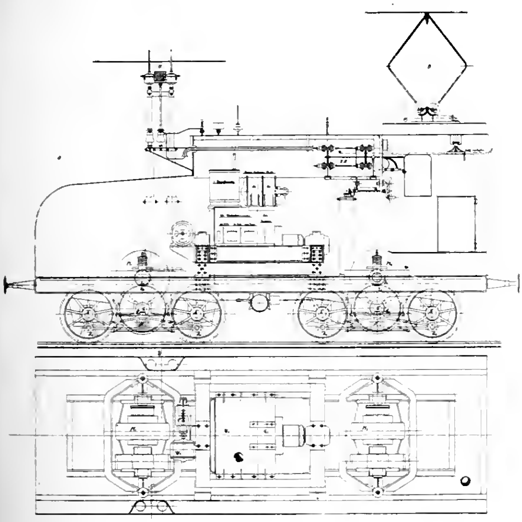

FIG. 5.—ELEVATION AND PLAN OF LOCOMOTIVE.

and at that time he did not have at his command data with reference to the additional weight and complication required by the multiple unit system, which would have naturally added further to his remarks in favor of the flexible controller offered. During the latter part of the year 1902 the Royal Commission of Swedish Engineers reported to the Crown upon the practicability of substituting electricity for steam power, and after carefully considering the various single-phase systems then extant, reported in detail upon the Ward Leonard system. This report was reported in the Swedish periodical, *Teknich Tidskrift,* of January 10, 17 and 24, 1903, and after making every proper allowance for the cost, operation and installation of the Ward Leonard system, a net yearly saving was estimated at $2,000,000. Details on the subject were given at the time in the pages of the Electrical World and Engineer.

In connection with the Oerlikon work the illustrations accompanying this article may be of some interest. In Fig. 2 is shown the locomotive arranged on the Ward Leonard system. It comprises in one frame a motor-generator. The traction motors are arranged so that they come one-half above the car floor, and are geared to an axle below which is connected to the wheel by means of connecting rods The controller cab shown in Fig. 1 displays various instruments and circuit breakers essential to the operation of the system and the rheostatic control is shown at the left. Fig. 3 exhibits in more detail the motor-generator, which, it will be seen, is a very compact and convenient machine.

Fig. 4 shows a section of the roadway, which is interesting because of its peculiar method of top contact, for the trolley wheel, the trolley resting on the top instead of on the bottom of the wire, as is common in American practice. Lastly, Fig. 5 displays to good advantage a diagram of the Ward Leonard locomotive, in which is shown the motor-generator exciter and its transformer, the main motor-generator, the traction motor and connecting rods, in which it is interesting to note the flexible sliding link connecting the motive shaft of the connecting rod.

It is to be hoped that the work of such a well-known American inventor may not be compelled to look exclusively abroad for its exploitation. Such experiments should be undertaken in America, and the present state of the art is such that careful work is certainly justified.

Institute Meeting on Air and Circuits Under High Voltages.

The 184th meeting of the American Institute of Electrical Engineers was held on February 26 at the Chemists' Club, New York City. The meeting was called to order by Vice-President Lieb and the secretary announced that at the meeting of the board of directors, held in the afternoon, 67 associates had been elected.

A very elaborate paper on "The Conductivity of the Atmosphere at High Voltages" was presented by Prof. Harris J. Ryan, of Cornell University. He first analyzed the results obtained several years ago by C. F. Scott in the laboratory in Pittsburg and afterwards by R. D. Mershon on the Telluride line in Colorado. Prof. Ryan deduced from theoretical considerations a formula which he had found to represent correctly Mershon's results, but not those of Scott, nor those of other tests in which he had himself repeated Mershon's tests in the laboratory. He then traced the disagreement to the fact that in his first formula he had neglected the influence of the temperature and pressure. He, therefore, studied this problem and arrived at the following final equation:

$$Emax = \frac{17.94\,b}{459 + t} \times 2{,}055\ log_{10} \left(\frac{s}{r} \right) D'\ (r + d) \times 10^{10}.$$

In this equation *Emax* is the maximum value of the voltage wave, applied to the line, b is the barometric pressure in inches of mercury, t is the temperature in degrees Fahrenheit, s is the distance of the line conductors from center to center in inches, r the radius of the line conductor in inches, d the distance from the conductor surface at which the strain due to the electrostatic field causes initial atmosphere rupture, and D' the strength of the electrostatic field of force (dielectric flux density) that will electrically rupture the atmosphere at the distance d from the surface of the conductor with radius r, D' being measured in coulombs per square inch.

For diameters of conductors larger than 0.250 inch, the values of d and D' are constant and the above equation assumes the simpler form.

$$Emax = \frac{17.94\,b}{459 + t} \times 350{,}000\ log_{10} \left(\frac{s}{r} \right) (r + .07)$$

The author had made efforts to determine the effects of the presence of moisture upon the point at which the atmosphere about high-voltage lines becomes conductive, i. e., upon the point at which the sudden rise in the loss curve occurs. However, no definite effect of this sort could be found, and this is practically in accord with Mershon's conclusions after his observations made upon the Telluride line under variable weather conditions.

From the above equations the following table was calculated by the author. It shows the corresponding diameters of line conductors that must be employed to avoid loss between wires for a series of line voltages wherein the barometric pressure is 29.5 in. of mercury, the temperature 70° F., and the distance between the conductors 48 in.

Maximum volts at which atmospheric conduction loss occurs.	Corresponding effective volts (sine wave).	Operating pressure 90 per cent. of corresponding effective volts.	Diameters of conductors in inches.
78,500	55,000	50,000	0.058
118,000	83,300	75,000	0.106
157,000	111,100	100,000	0.192
235,500	166,600	150,000	0.430
314,000	222,200	200,000	0.710
392,000	277,700	250,000	0.990

Prof. Ryan pointed out that the real voltage limit to-day in transmission is due to the insulator, where the line has to be exposed to the weather. In future the insulator difficulty will be solved in one way or another and higher voltages will be used. Possibly in large undertakings the line may be protected from the elements by means of a continuous covering. When such high voltages are employed atmospheric conduction, or "the brush," or, as Steinmetz calls it, the "corona" must be avoided. Prof. Ryan found that the brush discharge or corona occurs always when a definite strain exists in the atmosphere next to the high-voltage conductors, and that to avoid such corona with its destructiveness and waste of power, it is necessary on transmission lines and auxiliaries to proportion things so as to keep the dielectric strain of the atmosphere below a definite point, above which the corona will inevitably appear.

In the above table a factor of safety of 1.11, or a margin of 10 per cent. was allowed by Prof. Ryan in estimating the safe voltage at which to operate so as to avoid losses due to brush discharge; but this was a laboratory conclusion only.

Concerning the maximum of the voltage wave, Prof. Ryan pointed out that almost invariably the line charging current will cause an important line voltage wave—distortion—so that the maximum of the wave (upon which the corona formation primarily depends) will exceed the effective value of the voltage by a factor much greater than the square root of two. He also pointed out that the insulators must also be properly proportioned, otherwise the presence of the insulators made of material that has a considerably greater permeability to dielectric flux than the atmosphere, will cause corona to a greater or less degree to form over the conductors in their neighborhood. This will likely be accompanied by corona over the pins inside the insulators, resulting in their ultimate injury if made of wood, from this cause alone, even if the surface leakage current is so limited as not to injure the pin.

Prof. Ryan closed his paper with the suggestion that when viewed in the dark the corona, formed upon wires of given diameters and distances apart, provides a method for gauging high voltages that is free from the short-circuit and surging disturbances occasioned by the use of the spark discharge method. Either two parallel conductors or a conductor mounted at the center of a cylinder may be employed for this purpose.

The discussion was opened by Mr. C. F. Scott, who characterized Prof. Ryan's paper as a remarkable one, reaching out into the future and the unknown. It dealt with something beyond the present commercial practice, but something toward which the actual engineering work of the present time is fast approaching. Mr. Scott then spoke of his own experiments made in the laboratory in Pittsburg, and of those made by Mershon on the Telluride line, and presented a communication by Mr. S. M. Kintner, who pointed out that on account of the influence of temperature, if a range from 25° below zero in winter and 125° above in summer is taken, there would be a range of 30 per cent. in the voltage at which the corona would appear. With respect to the effect of the use of small or large wires upon the discharge, Mr. Kintner pointed out that this would indicate that blunt gaps are more reliable for measuring voltage than needle points.

Mr. Scott also read a communication from Mr. P. M. Lincoln, who first raised the question whether any loss in our present transmission lines is due to the corona effect. From Prof. Ryan's paper it follows that this is not the case. For the very worst conditions which would occur in actual practice, viz.: a No. 6 wire with a spacing of say 48 in., the corona loss at sea level does not begin until the voltage has reached the neighborhood of 100,000 effective. For the maximum altitude at which transmission is apt to be carried on, say 10,000 ft. above the sea level, the voltage at which the loss begins may be as low as 65,000 for the worst cases, but still considerably beyond the limits of the actual practice of to-day. Normal progress is bound to carry transmission voltages beyond those used to-day, hence it is important to consider which remedies are available to counteract the losses. It is well known that a good rubber insulation on the wire will almost entirely prevent the corona loss, at least within the lower limits of voltage at which the effect occurs. Mr. Lincoln pointed out that it would be interesting to determine the effect of various kinds of insulation on the loss.

Dr. S. Sheldon then spoke on the character of the various forms of discharges through air, as distinguished by the names glow discharge, brush discharge, spark and arc. The glow and brush discharges are probably due to a sort of gaseous ionization, and Dr. Sheldon is of the opinion that this corona discharge is a combination of both these discharges.

Prof. H. B. Smith spoke of an electrometer which he had devised for high potential measurement, and Mr. P. H. Thomas asked various questions which were answered by Prof. Ryan. It was pointed out that it would be interesting to compare the effect of substituting aluminum for copper wires upon the loss. Mr. Thomas stated that he had made direct measurements of the loss from the line into the air on a 50,000-volt plant, with a length of something less than 100 miles. The loss began to be measurable at about 20,000 or 25,000 volts and ran then up very steeply. At 60,000 volts the loss amounted to a total of 10 kw, which is insignificant for power transmission purposes, but yet a measurable loss.

A paper on "European Practice in the Construction and Operation of High-Pressure Transmission Lines and Insulators," by Mr. Guido Semenza, was then presented. In the absence of the author it was read by Mr. J. W. Lieb. The author pointed out that a transmission line needs just as much careful design as any electrical apparatus and first refers to the calculation of the best wire section; this problem is best solved by a graphical method. The next question is the route of the line. He then discussed at some length the comparative advantages of wooden and iron poles. The advantages of iron poles are, durability, the possibility of using large spans and lower cost of maintenance. Their disadvantages are a somewhat greater capital investment and the necessity of using better insulators. He thinks that the adoption of iron poles for important transmission lines will become more and more general.

The author gave an outline of the best way of proceeding in the design of a line, and discussed at length the design of insulators. Wooden cross arms are sometimes employed with iron poles; but, in general, supports constructed entirely of iron are preferable. A special cement is employed to fasten the insulators to these brackets, or, in the case of small lines, tarred rope is employed. This differs entirely from American practice, and no attempt is ever made in Italy to use threaded insulators, as it is difficult to obtain good insulators with thread of the exact gauge. The best cement for this purpose consists of 10 parts of litharge and 1 part of glycerine, well mixed. The brackets and insulators thus cemented together form an indivisible unit.

When the span exceeds a certain length, care must be taken that the wires do not come in contact through their oscillation due to the wind. It is obvious that in order to avoid such a contingency it is necessary that two or more wires should never be placed on the same level, and the adoption of cross arms as practised in America should not be followed, in the opinion of the author. In any case, it is easy to calculate the deflection of the wires from their vertical position, due to the force of the strongest wind prevailing in the country and midway of the span, thus finding the distance between the insulators to prevent the wires coming in contact.

The problem of high-pressure insulation is very carefully studied by European electricians. Glass insulators are not used in Europe probably because good porcelain can readily be obtained there. Glass is considered to have a better dielectric strength, but not as good surface insulation; moreover, glass is weaker against meteorological agencies, the superiority of porcelain being due to the materials composing the glazing. European engineers do not consider American porcelain as good as European porcelain. It is possible that they may be mistaken, but a few tests made by the author on American insulators showed a higher dielectric resistance for the European porcelain, which in appearance, finish and homogeneity of material is much better.

In designing an insulator the following points are to be considered: Dielectric resistance, resistance against surface arcing, mechanical strength, facility of cleaning, ease of construction.

The first two points have reference to electric qualities and an ideal insulator ought to be so proportioned that, under a certain voltage, it should break in both ways, by puncture and by surface arcing. The resistance against puncture can be increased by making the insulators of several pieces, introduced one piece inside the other. In general, the different pieces are cemented together with a kind of glazing in the process of manufacture and put on the market as single pieces.

The author does not follow this practice, but prefers having them furnished by the factory in separate pieces, for the following reason: When the thickness of the pocelain reaches a certain limit the ordinary testing will not puncture a sound insulator. In testing an insulator made up of two or more pieces, one layer of porcelain may be cracked, but is protected by the other layers. When the tests are performed on the single component parts, this cannot happen, and one is sure to have the insulators made up of sound parts. Moreover, each composing part can be better inspected and the character of glazing observed. Following this suggestion many factories produce insulators in two parts, which, after test, are put together with glycerine and litharge cement. Experience has demonstrated that it is useless to increase the number of component parts; up to 40,000 volts two parts are quite sufficient and above that voltage not more than three are necessary.

The ability of an insulator to resist surface arcing is due to its dimensions and shape, the latter to be considered under a double aspect, the protective action against moisture and rain; and the property of giving origin to electrostatic phenomena. An insulator with a very large petticoat on the top and only a second petticoat round the pin will not afford a very good protection against rain and moisture, as during a storm the inner petticoat will get quite wet. It is, therefore, good practice to have one or two intermediate petticoats, which will also insure the dryness of some part of the surface in all kinds of weather. Care must, however, be taken not to put on too many of them, as their edges would come too near, thus forming a good path for the arc, besides increasing the difficulty of cleaning the insulator. The use of intermediate petticoats should be limited to those strictly necessary to protect the inner part from rain and to insure that a part of the surface shall be quite dry.

The discussion was opened by Mr. Lieb, who said that the paper indicated the character of analysis which European engineers give to mechanical problems when they are presented. While perhaps European engineers may not be as active in undertaking pioneer work in new fields, particularly where much investment and commercial development are necessary, yet when these applications are once made by them the constructions are subjected to very careful analytical treatment. Mr. W. N. Smith remarked that the method of construction of the high-tension lines described in the paper is quite different from our usual practice and might perhaps lead to complications in this country, for instance, from the small boy nuisance.

President Arnold remarked that just such a line, as described in the paper, has almost been completed in Mexico. It is about 100 miles long, built with steel towers, regular wind mill towers, using seven poles to the mile and supposed to be the most modern line now built. When the New York Central Railroad recently considered the transmission question, the conclusion was reached that it is safer and more reliable in operation to have the transmission wires overhead on steel poles than to put them in conduits.

Mr. L. L. Perry remarked that some constructions shown in the paper might be due to local European conditions, for instance, narrow streets. Mr. W. E. Dix said that he thought that American insulator manufacturers are now adopting the suggestions of the writer of the paper, viz.: to reduce the number of petticoats, increasing the surface and also increasing the space between the petticoats, thus reducing arcing and leaking. Mr. C. F. Scott agreed with the author that there is a difference between the engineering inside the station and that outside the station. In many cases the external line construction lacks the standardization, the uniformity, and the higher grade of considerations which have generally been given to other departments of manufacture.

Big Searchlight for the World's Fair.

The General Electric Company is building the largest searchlight made. It is to take 300 amp. and the lens is 7 ft. in diameter. This will be used by the Clark Publishing Company, of St. Louis, on top of its tower which is being built adjoining the World's Fair grounds. It is not unlikely that experiments with telephony over this searchlight beam will be made during the progress of the Fair.

Early Days of the Brush Arc Light.

By S. M. Hamill.

The wonderful story of the past twenty-five years of the development of the electric business is ever new to all of us. The able men of the electrical journals who from week to week have chronicled this story, educators in the business, constantly stirring up the new and raking over the old, have exerted a powerful influence for which the world owes them a debt of gratitude.

The Brush Electric Company was the first in the field in the era you celebrate this week. Stockly, its president, and his assistants, Tracy, Swift and Potter, were men of energy and ability. From 1879 to 1884 they accomplished a great work. The Brush system of arc lighting was soon perfected and it was pushed for all there was in it. The first series street arc lights were erected in the Public Square in Cleveland, Ohio, in 1879. Shortly thereafter local electric light companies were started in all the large cities and towns in the country. Millions of dollars were raised for the purpose. Leading men of the country were induced to invest their money and to take part in the management of the enterprises. Europe and Asia did not escape. Even to-day, in England, the Brush influences persist. Potter in the early eighties organized local companies in Japan and China. Brush with his genius for designing and constructing a new system that worked well. Stockly with his few energetic able assistants, accomplished results seldom equalled in the history of any new industry.

They were pioneers of the highest order: First, in the electric lighting field; second, in getting rich quickly in the electric business; third, in selling their company to a modern combination.

We may not yet be far enough away from Brush's early work in the development of electrical apparatus and his electric lighting system in order to appreciate fully what he accomplished. Time will place him on a lofty pedestal. So far as his actual accomplishments were concerned, during the early days prior to 1884 he was easily the leader. Between the years 1878 and 1884 he rose rapidly to prominence, and his name and reputation were world-wide. Distinguished honors abroad were conferred upon him. The apparatus which he designed and the building of which he superintended was widely used, and brought him and his immediate associates large fortunes.

Brush was a university-bred man, having graduated from the University of Michigan in 1869 with the degree of Mechanical Engineer. This was rare and was before the days of electrical engineering schools and accounts in part for the mechanical perfection of his apparatus.

While the factory of the Brush Company in the early days of its history was small in comparison with the great factories of to-day, yet for its time it was enormous, and turned out millions of dollars worth of apparatus which was shipped to all parts of the globe. Many of the engineers, or what were so commonly called "inventors" in the early days of electric lighting were not particularly good business men. The fact that few, if any of them, have amassed any wealth indicates this. Brush had very keen business instincts and not only was fortunate in his business arrangements with his company, but was a wise and conservative adviser. He loved work, which was always done thoroughly and remarkably well. The Brush dynamo so largely used to-day is to all intents and purposes the same as that designed and built by Brush in 1878. The arc lamp, with his magnetic cut-out for series circuits, the storage battery and the arc light carbon, each the foundation of a great industry, have not drifted very far from his original ideas and inventions.

In 1879 Brush was poor; in 1886 he was very rich, with a beautiful home and large grounds in Cleveland, O., where he lives to-day, devoting his time to scientific work in his laboratory and in caring for his large interests. Take it all in all, no one man has contributed more than Brush to make this electrical age what it is; and to the writer, intimate association with such a leader has not been the least pleasure of a laborious electrical career.

Wireless Telegraphy for Russia.

A dispatch from Paris says: "In order to prevent interruption of the telegraphic service during field operations in the Far East, a French company of wireless telegraphy is arranging to provide the Russian Government with a wireless system which will enable it to communicate between stations thirty miles apart."

Great Northern and City Railway, London, England.

The latest London electric railway opened to traffic is a line which joins the Great Northern Railroad station at Finsbury Park, just at the four-mile radius, with the heart of the city in an almost straight line. It is 3½ miles long and furnishes the shortest and most direct underground route from this station to London's business section. The new line runs through a very densely populated district of workers, who, up to the present time, depended for entrance to the city on omnibuses and tramways, both of which take considerably more than double the time to reach the city than is required by the tube trains. This economy in time is expected to attract a great deal of traffic. It is estimated that at least 5,000,000 passengers per mile, or a total of 17,000,000 passengers per annum, may be looked for from local business alone. These figures are considered very conservative, as the Central London Railway, for instance, is carrying about 7,000,000 passengers per mile per annum. About 30,000,000 passengers per annum are brought to Finsbury Park, via the suburban trains of the Great Northern Railway. It is figured that at least one-third of these passengers will use the new direct line in preference to the roundabout older ones, thus adding 10,000,000 passengers per annum, making an annual total of 27,000,000 passengers.

The underground portion of the line consists of two 16-ft. diameter tunnels, opening out to nearly 23 ft. diameter at the stations. As

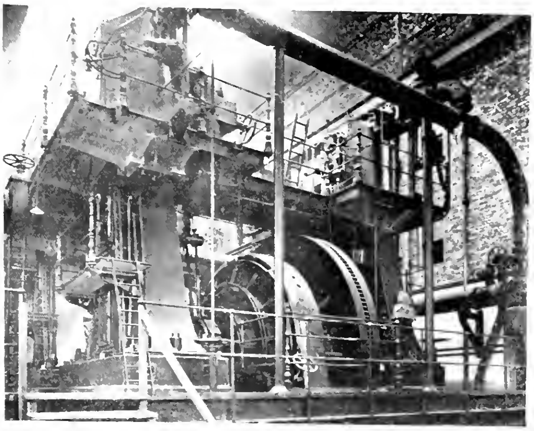

FIG. 1.—ONE OF THE UNITS.

the diameter of the Central London Railway tubes is 11 ft. 8 ins., and the City & South London Railway only 10 ft. 6 in., the new line is able to carry larger rolling stock and enjoy much better ventilation than the others. The track and tunnels are also arranged to permit the standard cars of the Great Northern Railway to run through the Great Northern & City Railway's tubes should it be found desirable to make the necessary connections.

A novelty in connection with the construction of the tunnels is the introduction, for a very great proportion of their length, of a vitrified blue brick invert. It has been demonstrated by trial runs that this material combined with a cast-iron roof will minimize noise and vibration. It is less resonant than complete iron rings, and the fact that the tubes are constructed of such different materials makes the transmission of sound waves more difficult with a consequent noise reduction.

The standard trains are made up of seven cars, three motor and four trailers, having a total approximate seating capacity of 430. The first motor car is at the front of the train, the second in the center, and the third at the end. The approximate weight of the loaded train is 200 tons.

The cars were built by the Electric Railway & Tramway Carriage Works and the Brush Electrical Engineering Company. They are supplied with Westinghouse quick-acting brakes. Each motor car carries a British Thomson-Houston motor-driven air compressor, reservoir, etc. There are also conductors' emergency cocks at the end of each car for applying the brakes in case of need.

Each motor car is carried on two McGuire trucks, having 36-in. diameter driving wheels. The trailer cars are mounted on Brush trucks. On each truck of the motor cars is mounted one 550-volt, series wound, direct-current motor. Current is collected by four collector shoes per truck.

The capacity of each motor is 125 hp, rated on the basis of 75° C. rise in temperature above the surrounding air after one hour's run on full rated load. The gear is of steel, machine cut, and enclosed in a waterproof case. The motors are controlled by the General Electric multiple-unit system. An interesting fact in connection with this installation is that the Great Northern & City Railroad was the first British electric railway to adopt the multiple-unit control system.

A 3-minute service will be introduced, single trips being completed in 13½ minutes, which permits four intermediate of 20 seconds each. The trains will be shuttled at the termini thus avoiding shunting around the stations. It is hoped to be able to maintain a 3-minute service throughout the day simply by shortening the trains, so that they may be run profitably on each short headway.

The power for operating the system is supplied from a single generating station located at Poole Street, New North Road, about a mile north of Moorgate Street station. The length (3½ miles) of the line and position of the generating system are such as to enable the system to be operated without feeding in at several points, the current being transmitted directly to the collector rails. The generating machinery also furnishes the current for lighting and the operation of the passenger elevators.

The site adjoins the Regent's Canal, from which water is being taken for condensing and other purposes, and returned to the canal at a point 300 ft. on the down-lock side of the in-take. Its connection with the Regent's Canal also permits fuel to be delivered cheaply alongside, from whence it is conveyed to the storage bins and fires by a Hunt gravity bucket conveyor, which handles 30 tons of coal an hour.

Steam is supplied by ten boilers, each having an effective grate area of 40 square feet and capable of evaporating 11,200 pounds of water per hour at 212° F. when using coal giving 13,500 B.T.U. The boilers are fitted with automatic stokers, driven by two motors.

The four main engines are of the vertical cross-compound type, built by John Musgrave & Sons, Bolton. The engines give 1,250 hp at 100 r.p.m. and 150 pounds pressure. They have fly-wheels weighing about 45 tons each, and are capable of sustaining 100 per cent. overload momentarily. They are direct-connected to four railway-type generators, rated at 800 kw each, but capable of taking for two hours, without objectionable heating, a load up to 1,200 kw. These generators are also able to carry momentary overloads of 100 per cent. without injurious sparking. They are British Thomson-Houston compound-wound to give 525 volts at no load and 575 volts at full load.

Two engines of the single-acting, tandem-compound type, built by Davey, Paxman & Co., drive two B. T. H. six-pole 120-kw generators at 375 r.p.m. They are compound-wound for the same voltage as the main generators, and have an overload capacity of 50 per cent. for two hours. They will supply power for lighting of power house, etc., and for operating the electrically-driven auxiliary plant when it is not convenient to take power from the main generators for this purpose.

There are four Wheeler surface condensers, each having a cooling surface of 2,400 sq. ft., and arranged with steam-driven combined air and circulating pumps. They are capable of maintaining a 26-in. vacuum when dealing with 2,200 pounds of steam per hour. There is also an auxiliary condenser of the same type, capable of handling the auxiliary plant and boiler feed pumps' exhaust. These condensers discharge into a hot well, from which the water is delivered by two three-throw vertical lift pumps of the Blake-Knowles type, driven by enclosed motors. All the condensers have combined air and circulating pumps, driven by steam. In addition to the supply from the canal mentioned previously, water can be obtained from the city mains. A storage tank has been provided connected directly to the latter.

The water taken from the canal is dirty, and varies in hardness from time to time during the year by reason of floods and droughts. For softening and purifying both this and the town water, which is also variable, a Desrumaux plant has been installed in the rear of the boiler house, capable of treating 8,500 gallons per hour. This gives water having its hardness reduced to 5° and alkalinity to about 6°, free from solids. An automatic arrangement is adjusted between the softener and storage tank, whereby the softening process is suspended and recommenced as occasion may require, thus giving a continuous supply of purified and softened water, with a minimum of

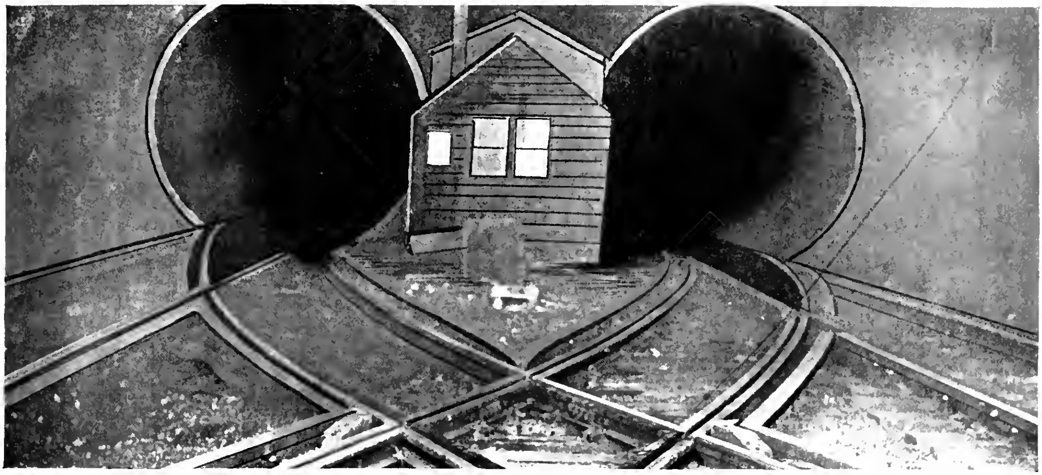

Fig. 2.—Entrance to the Tunnels.

supervision. A Masson-Scott plan is installed for removal of oil and grease from the water of condensation and for the purification of the water for boiler feed purposes. This plant is capable of dealing with 10,000 gallons per hour.

The oil and grease which has passed through the steam engines is in the form of a divided emulsion, so fine in its character that it

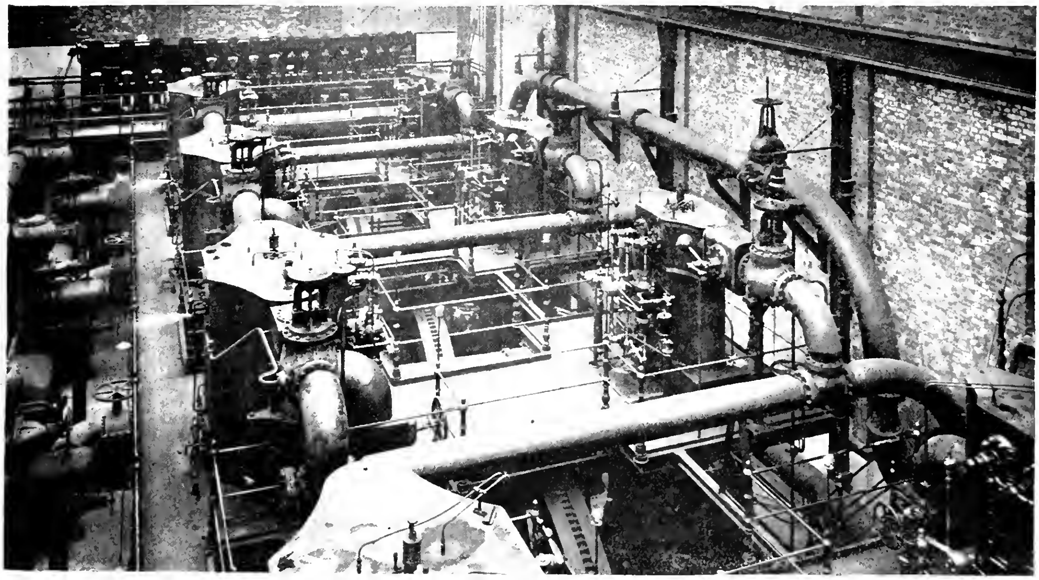

Fig. 3.—General View of Power Station.

is impossible to remove it by mechanical filtration alone, chemical treatment as well as filtration being essential. The apparatus is thus a combined plant for first chemically treating, and finally filtering every gallon of water which leaves the surface condensers, producing a perfectly clear effluent, free from grease of chemical admixtures and of a fixed degree of hardness suitable for boiler feed purposes.

A switchboard, consisting of four main-generator, four-feeder, two auxiliary generator panels, three-auxiliary power and three-auxiliary light panels, is installed in a gallery at one end of the engine room, commanding a view of all the main generators. The circuit breakers are of the magnetic blow out type, and the measuring instruments of the astatic illuminated dial and feeder type.

Cables run from the switchboard along the outside of the boiler house wall and then down a special cable shaft into the tunnels. The bus-bars on the board are so divided that the auxiliary-generator lighting and auxiliary-motor panels can be isolated from the main generator and heavy feeder panels by the operation of one switch, insuring the uninterrupted operation of the lighting system if any accident occurs to the main power circuits. Separate paper-insulated feeding cables are provided for traction, for lighting and for elevators, and rubber insulated cables for lamp circuits and connections.

The other station plant comprises steam-driven feed pumps, motor-driven economizer, two motor-driven lift pumps, storage and receiving tanks, water softening plant, one 30-ton three-motor overhead crane, etc.

Two insulated conducting rails are used per track, one being for the return circuit. Both rails are placed outside of the running rails. The conducting rails are of channel section, weight 80 pounds per yard, and are rolled to about 42-ft lengths. They are of a special quality of low-carbon steel, having a conductivity of 14 per cent. of that of pure copper of equal area. These rails are supported on earthenware insulators, 10 in. outside of the gage, carried on spindles supported by cast-iron brackets fixed to the sleepers. The system of collector rails is divided up into four sections, fed independently from the generating station. The running track is laid to standard gage, consisting of 85-pound flanged rails laid on longitudinal stringers in the tunnels and on cross-ties in the open. As it carries no current it is not bonded.

All lighting circuits are carried in iron tubes, and the tunnels are

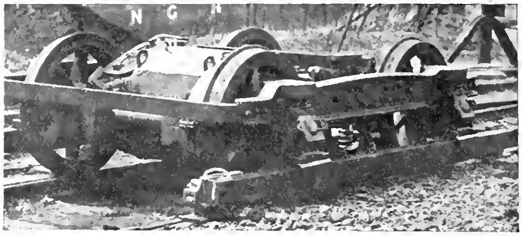

FIG. 4.—VIEW OF ONE OF THE TRUCKS.

provided with lamps every 100 ft. The passenger stations are lighted on the rail and street level by enclosed arc lamps, and station switches are fixed which control the incandescent lamps in the tunnel halfway to the next station in each direction. The lamps are placed five in series, and the circuits are run so that there is never more than the voltage of one lamp between two adjacent wires in the same pipe. Special throw-over switches are provided to take the lighting current from the conductor rails when the special lighting cables are not charged.

Power Transmission in Washington State.

Mr. Herbert Hunt, of Everett, Wash., furnishes some interesting details as to the May Creek power plant of the Everett Railway & Electric Company, on Lake Isabel, 32 miles east of that city. The plant is designed to furnish 15,000 hp to Everett for the street railway, public lighting and private power, as well as for the Everett-Snohomish interurban line of 12 miles, and later to supply other interurban trolley lines which this company will build.

The intake for the 32-in. steel pipe will be 30 ft. below the surface of Lake Isabel. The pipe will be carried 12,000 ft., with a fall in that distance of 2,500 ft. This distance will be shortened by 4,000 ft. if the company determines to tunnel a granite hill lying between the lake and site for the power house. Owing to the pressure special steel pipe has been ordered. Toward the nozzle the pipe decreases in diameter to 20 in.

The diameter of the nozzle itself will be but 5/8 of an inch. A wheel of the Pelton type will be used. One 5/8-in. stream will develop 10,000 hp. Later, when additional power is needed, another stream and wheel will be installed, developing 6,700 hp additional. The pressure on the steel pipe is 1,100 pounds to the sq. in. The speed of the water leaving the nozzle is 25,000 ft., or more than four miles a minute. The cost of the plant will be about $600,000, and it will take the place of a fine steam plant built two years ago.

The outlet of Lake Isabel will be dammed, thus storing enough water for a six months' run. This is not necessary, but is a precautionary measure. May Creek is not large, but is a tumbling mountain stream flowing into the lake, and is never dry, so far as the oldest inhabitant knows. The company is now building roads to the lake, which is a little more than a mile from the Great Northern tracks.

Power Lines Near Ocean.

It is stated that the transmission wire of the United Electric Gas & Power Company, through Santa Monica, Cal., is to be removed from Speedway and carried back to Eighth Street, extended on to Redondo, San Pedro and Long Beach. The close proximity to the ocean, it is thought, has been the cause of the frequent sparking of the poles by the 22,000 volts carried through the wire. The company is reconstructing its transmission lines and using only iron poles in the new work.

New Telephone Patents.

IMPROVED SWITCHBOARD CONNECTING CORDS.

Wherever flexible electrical conductors have been required it has been well nigh universal practice to built them up out of numerous strands of small diameter. In telephone work tinsel strands have been largely used, and prior to the introduction of the common battery system such conductors were considered amply good for any service. With this modern system, wherever a continuous current is conducted, considerable annoyance may be experienced from the breaking of a few of the tinsel strands, the loose contacts at the break serving as microphones. To obviate this difficulty in switchboard connecting cords, which are subjected to great wear, a cord having single-strand conductors has been designed by Mr. H. B. Holmes, of Evanston, Ill. This is a three-conductor cord, the conductors being spiraled up in a manner such that while the whole is sufficiently flexible all bending takes place upon a radius of sufficient length to distribute strains.

In Fig. 1 is shown a section of cord partially fanned out to render the construction clear. It will be noted that a hemped string forms

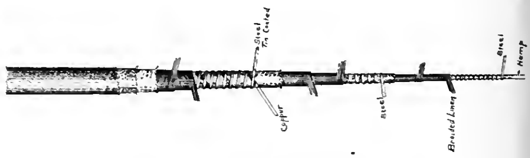

FIG. 1.—HOLMES CONNECTING CORD.

the core. About this core a thin ribbon of spring steel strip .008 in. thick and .025 in. wide, tinned to prevent corrosion, is tightly wound making approximately twenty-two turns to the inch. Two layers of silk floss and a braid of linen follow. Then comes the second ribbon conductor, spiraled in the reverse direction from the first and making eighteen turns per inch. Floss and braiding follow, as for the first conductor. These two conductors have resistances respectively of nine and eleven ohms for a seven-foot cord and are to be used for the talking circuit.

Now follows the signal conductor, for which the resistance must be kept low in order not to disturb the current ratios of existing systems. This conductor consists of a copper ribbon wound on in one direction and a steel ribbon wound in the reverse direction, the copper lying beneath at four turns to the inch, and the steel at fourteen turns to the inch. This combined conductor has a resistance of two and a half ohms per seven feet. The cord is finished with braiding and reinforcing in the usual way. This cord is apparently of a construction to stand great wear and tear, and should have a life considerably greater than the tinsel cord. The Western Electric Company have obtained this patent by assignment.

CENTRAL ENERGY CIRCUITS.

A two-wire central energy system has been patented by W. M. Davis, of Chicago. A differential line relay is used, one winding of which is so arranged that it becomes shunted by the insertion of a plug in the associated line jack. The armature of the relay then, of course, comes up, thus opening the line signal circuit. The connecting cord circuit runs directly from plug to plug for one side of the line, while for the other a condenser is inserted to permit of the use of two supervisory signals. The supervisory relays which control the lamps through back contacts serve as retardation coils through which current is fed to the subscribers' lines. This arrangement of relay, of course, corresponds to a closed circuit for the lamps, when the cords are not in use; and, therefore, the lamp circuit must be opened independently of the relays by the removal of the plugs from the spring jacks. This is accomplished by making a portion of the circuit common for the lamp and for talking, this common portion including the plug and jack. Mr. Davis has assigned his patent to the Stromberg-Carlson Company.

NEW DESIGN OF JACK.

A two-wire system jack recently patented by Alfred Stromberg has also been assigned to the Stromberg-Carlson Company. This is designed for a system slightly different from that just described. This may be called a "bank" jack, being built in groups or banks of one hundred. Fig. 2 shows the construction fairly well. The front plate of hard rubber is shown at 1. The back plate, 5, in which the springs are mounted is built up of rubber strips. The jack thimble, it will be noticed, is not spun into position according to standard custom, but is held by its conducting extension being riveted to one of the line springs. At the ends of the bank metal

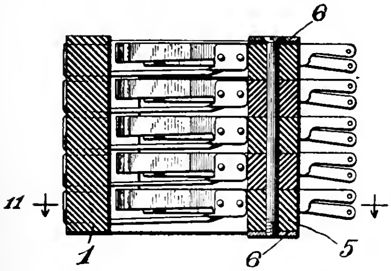

FIG. 2.—STROMBERG SWITCHBOARD.

spacing pieces are run across from front to back, to maintain the parts in their proper relative positions.

TRANSMITTERS.

Something quite peculiar in transmitters appears in a patent which has been issued to Pierre Germain, of France. This transmitter is provided with a heating coil which surrounds the carbon electrodes, the inventor stating that these work best when at about 80° C. Another feature is a supply of sodium or similar substance within the casing of the transmitter. This is designed to absorb moisture and oxygen to prevent corrosion of the parts. The third feature of note is the mixing of metallic oxides with the carbon of the microphone. In some cases it is mixed before baking; in others, after baking.

Two other transmitter patents relate to an instrument for the use of the deaf. The transmitter described is a double affair, being composed of what is practically two transmitters with their mouthpieces removed and their inlets opposed. Leading into these inlets are two curved sound passages, so shaped that two currents of air meet, the idea being to make the sound wave disturbances spread out over the diaphragms in virtue of the meeting of the two passages. The casing of each element is perforated with numerous small holes in a manner such that these serve to connect the outside air directly with the air spaces in front of the diaphragms. The inventor, H. G. Pope, of Brooklyn, N. Y., states that this perforation promotes clearness.

RECEIVER SUPPORT.

The receiver support has again appeared, this time in a form rather more commendable than some of those of earlier design. This support has an attachment engaging the hook switch in a manner such that the hook is not depressed except when the ear of the user is forcing it to one side. G. B. Buchanan, of Haverstraw, N. Y., is the patentee of this holder.

RINGING DEVICES.

An apparatus for ringing from subscribers' stations without the use of a magneto has been patented by O. O. Lee, of Chicago. Mr. Lee employs an auxiliary hook switch contact which is closed only when the hook is near the mid-position of its stroke. When this contact is held closed, a vibrator, associated with the induction coil, begins to move, rapidly breaking and making the primary circuit of the induction coil. The secondary sends out impulses of alternating current to the line. A rather powerful battery must be used for the ringing, a cell or two of this being used for the talking circuit.

Another ringing device is one patented by W. D. Watkins, of San José, Cal., designed for selective signaling. This is a step-by-step mechanism of very simple construction. The pawl operating armature is worked under the influence of the coils of the ringer while the selective device does not render any circuit changes necessary, being dependent upon releasing one bell hammer after another as the parts rotate, by the withdrawal of a stop which normally restrains its motions.

Two other step-by-step selective devices are subjects of patents in the issue under consideration. These are respectively the work of R. Hamilton, of Milton, Mass., and Messrs. H. Redmon, R. L. Hall and R. H. Conway, of Cynthiana, Ky. The apparatus and methods of operation of the two systems are markedly different, yet both involve merely the usual features of such systems, with the possible exception that special attention has been given to synchronizing all the instruments of a line after its use.

CURRENT NEWS AND NOTES.

LONDON STREET LIGHTING.—The most recent returns show that the streets of the 118½ square miles of London are lighted by 4,974 electric arc lights, 1,185 electric incandescent lights, 56,690 incandescent gas lamps and 18,248 flat flame gas burners. This leaves a lot of work ahead for electricity.

TELEPHONY IN CHINA.—For some time the introduction of the telephone in Canton, China, has been talked of, and is now said to be a *fait accompli*, the arrangement being in the hands of the Imperial authorities. All the large yamens will have the advantage of this new departure, and many large dealers and banks will also be provided for. It may not be generally known that some years ago the telephone was introduced in Shameen, but very high charges were made, and the enterprise proved a failure.

BRITISH TRAMWAYS.—During 1903 the number of passengers carried by the tramway system in the United Kingdom reached the number of 1,681,948,655, an increase of 287,495,672 over 1902, while the mileage had increased from 1,482 to 1,772 miles. The number of companies operating was 296. In 1894, 30,528 horses were at work in connection with the tramways in England; in 1902 the number was 24,120, but last year the total fell to 20,005, and the number is destined still to diminish, as the tramways are rapidly becoming electrified.

MORE SUBWAYS FOR NEW YORK.—The Metropolitan (Interurban) Street Railway system of New York has laid plans before the Rapid Transit Commission for a complete underground system to be operated under a 5-cent transfer system in connection with the 500 miles of Metropolitan surface line. Mr. Parsons is quoted as saying that the system will take about $40,000,000 to build, as compared with $35,000,000 for the Belmont subway now nearly ready for use. At the best, the Metropolitan system can hardly be ready before the growth of population has more than overtaken the new facilities.

PIPE THAWING IN NEWARK, N. J.—During the recent severe cold spell, the Street and Water Board of Newark, N. J., adopted the electrical method of thawing out water pipes. The transformer and rheostat were put upon a wagon and moved from place to place. When one service pipe was to be thawed out a wire was attached to a faucet in the kitchen or laundry and the other was fastened to a fire plug in the street. In five minutes the ice in the pipe thawed out to the main, and steaming water ran from the faucet. When two houses which were in trouble were close together, one wire was attached to the faucet in the first house and the other to that in the next. The frost went so deep into the ground that there was trouble all over the city, and the authorities cleared twenty or thirty pipes a day by this novel method. It was done gratis where the pipes have been laid from the mains to the houses by the city, which is the case with all that have been laid in the last ten years. Otherwise the cost was $5 or $10. By the old means of digging up the street it would cost from $25 to $50.

BOHEMIAN PITCHBLENDE.—Mr. N. J. Ledoux, United States Consul at Prague, Austria, writes as follows: "The government mines at St. Joachimsthal, which have become famous since the discovery of radium, are in Bohemia. In the course of the manufacture of uranium colors, the radioactive element of the pitchblende (radium, etc.) remains in the residue of the alkaline solution of patassium salt, which, since the discovery of the fact that it contains radioactive substances, is being evaporated and sold to chemical works and institutions of learning for the manufacture of radium preparations. The quantity of residue of alkaline solution of potassium salts amounts, according to the extent of the manufacture of uranium colors, to 11,000 to 17,600 pounds per annum. Orders for this residue should be addressed as follows: 'K. K. Bergwerksproduktion-Verschleiss-Direction, Vienna, Austria,' or to 'K. K. Berg-und Hüttenverkaltung, St. Joachimsthal, Bohemia, Austria.' There is, however, no pitchblende for sale now. Application should be addressed to the above-named officials for proper attention when any available supply is on hand."

NERNST LAMPS FOR ST. LOUIS EXPOSITION.—The Art Building interior at the St. Louis Exposition will be lighted by Nernst lamps. The white light of this lamp should adapt excellently to the illumination of paintings so as to give approximately a daylight effect.

WIRELESS TELEGRAPH INSTRUCTION.—The Navy Department is making preparations to transfer the wireless telegraphy school for enlisted men from Newport to the Navy Yard at New York, where better facilities are afforded for this work. It is intended to assemble there all men under electrical instruction, both in wireless telegraphy and other branches.

NEW CABLE TO JAPAN.—The *Bourse Gazette,* of St. Petersburg, commenting on the report that the United States has undertaken to lay a submarine cable from the Philippine Islands to Japan, to prevent the latter's isolation in case the Russians cut the Shanghai cable, makes a bitter attack upon the United States Government "for this new evidence of its breach of neutrality," claiming that the contention of the United States that the laying of the cable will be undertaken for the improvement of trade relations "does not clear America's skirts," and inquiring "what the Americans would say if Germany had run a cable from Kiaochou to Port Arthur or Vladivostok?" Washington dispatches on February 24 said that the Commercial Cable Company had addressed inquiries to the government as to whether permission could be secured to land on the island of Guam a cable connecting with Japan. This cable would connect at Guam with the present Pacific Commercial cable to the United States. It was said that the request was based on the apprehension that the existing Japanese cables, both of which run to Shanghai, might be cut during the present hostilities, and Japan thus be isolated from the world. In considering the request the government was said to have reached the conclusion that an assent would not involve a breach of neutrality, taking the ground that a cable is a commercial instrument like a mailship.

RUSSIAN TELEGRAPH CENSORSHIP.—The Russian Government has abolished the censorship upon all news and other telegrams going abroad. The lifting of the embargo, which has existed for generations upon the free transmission of news from the Russian Empire, came as a direct result of the consideration of the subject by the Czar himself, and in some respects this abolition is regarded there as the most important act since the emancipation of the serfs. Foreign telegrams, until recently, were subject to censorship at the Ministry of Foreign Affairs, but, since the death last autumn of M. Gretch, who was at one time connected with the Russian Embassy at Washington, the censorship has been temporarily under the Ministry of the Interior, where the permanent censorship bureau of plays, books and newspapers in Russia is located. News telegrams addressed to foreign sources originating in the most distant parts of the empire, Vladivostok, for example, were formerly telegraphed to St. Petersburg to be passed on. M. de Plehve, Minister of the Interior, and Count Lamsdorff, the Foreign Minister, both joined in the recommendation that the censorship be abolished. The internal censorship is to be retained, but foreign dispatches are to be entirely free. Inasmuch as a state of war exists, telegrams from the theatre of hostilities will be subject to the same kind of military censorship enforced in all countries under similar circumstances.

N. E. L. A.—Mr. Ernest H. Davis, secretary of the National Electric Light Association, reports that for the Question Box at the Boston convention, next May, nearly 300 questions for Mr. Hartman to get answered, have come in. The new active members of the Association are: Montgomery Light and Water Power Company, Montgomery, Ala.; Hot Springs Water Company, Hot Springs, Ark.; Monterey County Gas and Electric Company, Monterey, Cal.; Moscow Electric Light and Power Company, Moscow, Idaho; Freeport Railway Light and Power Company, Freeport, Ill.; Richmond Light, Heat and Power Company, Richmond, Ind.; Keokuk Electric Railway and Power Company, Keokuk, Iowa; Waterloo and Cedar Falls Gas and Electric Company, Waterloo, Iowa; The Electric Railway, Light and Ice Company, Junction City, Kan.; Clinton Gas Light Company, Clinton, Mass.; Great Barrington Electric Light Company, Great Barrington, Mass.; Edison Sault Electric Company, Sault Ste. Marie, Mich.; Edison Electric Light and Power Company, Amsterdam, N. Y.; The Allegheny County Light Company, Pittsburgh, Pa.; Newport and Fall River Street Railway Company, Newport, R. I.; Bristol Gas and Electric Company, Bristol, Tenn.; Burlington Light and Power Company, Burlington, Vt.; The Washington Water Power Company, Spokane, Wash. The new associate members are: Ford, Bacon & Davis, New York City; American Conduit Company, New York City; B. D. Nath, Schenectady, N. Y.; William Thomas Taylor, Schenectady, N. Y.

LETTERS TO THE EDITORS.

Steam Turbine Economy.

To the Editors of Electrical World and Engineer:

SIRS:—Referring to the article by Mr. A. N. Mattice in your issue of February 20, on the 1,250-hp steam turbine for the Interborough Company, the economies shown are certainly very good, but it is unfortunate that Mr. Mattice does not give the consumption of the auxiliaries, particularly the air and circulating pumps and superheaters.

Articles of this kind are apt to be misleading and as an illustration, the operation of a compound reciprocating engine by means of the air pump may be cited, where no steam is actually consumed by the engine itself, the work being done entirely by the "vacuum," i. e., atmospheric pressure.

We have been informed so many times by the manufacturers of turbines, of the necessity of high—in fact almost theoretical—vacuum, that it is somewhat of a question if the high economies claimed are not more than offset by the means adopted to obtain them; viz., the use of large air and circulating pumps, and super-heaters, etc.

CHICAGO. CYRUS ROBINSON.

Theory of the Repulsion Motor.

To the Editors of Electrical World and Engineer:

SIRS:—I have read with much interest the data published in the ELECTRICAL WORLD AND ENGINEER on page 266 and following, on the subject of repulsion motors of the General Electric Company. The information, as well as the discussion by Mr. Steinmetz confirms fully the elementary theory of the repulsion motor which I gave last year (see *Elek. Zeitschrift,* June 11, 1903), and which was later developed by several authors.

In the article referred to I pointed out the fundamental characteristic and that which decides the future of the repulsion motor; that is to say, in this motor there is produced a true revolving magnetic field which in itself suffices to insure a perfect commutation of the motor at normal speed. I am, therefore, convinced that the large motors of the General Electric Company, if they are satisfactorily dimensioned, will operate at normal speed with a commutation equivalent to that of the best continuous-current dynamos. Under the above conditions it is not necessary to establish a comparison between the repulsion motor and the ordinary series motor. In fact, an ordinary series motor of 100 hp, 25 cycles (I refer to a motor with a continuous output of 100 hp) has an impossible commutation. High-resistance connections between the armature leads and commutator undoubtedly improve the commutation, but not to a sufficient degree.

The repulsion motor is manifestly superior to the series motor at normal speed of operation, but conditions of commutation during the period of starting are the same for both motors. In this respect it is quite certain that the large motors of the General Electric Company commutate badly during the period of starting unless some special and novel arrangements have been adopted to avoid this effect.

The repulsion motor is the only serious competitor of my series compensated motor with power factor unity. Large motors built according to my design evidently present during the period of starting commutation difficulties which are the same as those of large repulsion motors. I have, however, discovered several new improvements which entirely overcome the defects for both kinds of motors, and I intend to describe these improvements later.

Concerning discussions of efficiency, power factor and weight of the ordinary series motor and the repulsion motor, I would say that they cannot bring forth any new results other than those which have already been obtained with single-phase induction motors.

PARIS, FRANCE. MARIUS LATOUR.

Single-Phase Alternating Current Motors.

To the Editors of Electrical World and Engineer:

SIRS:—My attention has been called to the luminous sketch contained in your issue of February 13 describing the widely heralded Westinghouse (Lamme) alternating-current railway motor. (Blow ye trumpeters, blow!) And I have read the entire article with much pleasure and some profit. ('Tis always pleasant to meet old friends.) The following startlingly novel discoveries are disclosed:

1st. With alternating currents laminate the magnetic circuits.

2d. To reduce secondary circuits in the armature circuits insert resistance. Formula, $I = \dfrac{E}{R}$. This failing, do something else.

3d. To reduce the inductance of the motor.—*A.* Decrease the applied frequency. *B.* Unwind the field coils. *C.* Demagnetize the blessed thing.

4th. To get good commutation—commutate.

5th. To make the motor work with alternating currents, make the alternating currents work the motor.

6th. To make it work better, patent it. (Don't patent it plainly, just patent it so the experts can have a chance to tell the truth.)

7th. If it looks a little old and seedy, get a new name plate.

From the above data I draw the following conclusions: There are two fundamental methods of producing inventions—first, make them; second, take them. Yours very truly,

WILLIAM STANLEY.

P. S.—If the above is not entirely clear—

Ask Weston about the multiple armature winding used about 1880.

Ask Kelly about the armature resistances used about 1891.

Look at patent No. 479,675, July 26, 1892, for the rest of it.

BROOKSIDE, February 20, 1904. W. S.

[Following is a reprint of the specifications, drawings and claims of Patent No. 479,675, issued July 26, 1892, to William Stanley, Jr., and John F. Kelly, on an application filed November 4, 1891, the title being "Alternating-Current Motor."—EDS.]

This invention relates, mainly, to electro-magnetic motors designed or adapted to be operated by alternating currents.

The special form of motor contemplated as within the limits of the applicability of the invention may be very widely varied; but for purposes of illustration the invention will be described as applied to any ordinary type of motor having a commutator and armature-winding similar to those existing in continuous-current generators and motors and a field magnet (which should be laminated or magnetically subdivided) energized by coils in series with or in derivation to the armature-circuit. If an alternating current be caused to flow through the armature coils of such a motor, it will, as is well understood, be subject to a given retardation, due to the self-induction of the armature. In fact, it has been found that this retardation may be and generally is sufficient to very seriously impair the efficiency of the machine. It may be corrected or neutralized in its effects and the trouble due thereto avoided by the employment in the circuit of a condenser of suitable capacity; but when the whole of the energy to be transmitted must pass through the condenser the latter becomes a large and costly adjunct and the apparatus as a whole becomes less available for general service. It will be understood that if on the armature a second winding were applied symmetrical with the first, but in which the current passes in a direction opposite to that of the current of the first, that no self-induction, and in consequence no lag, would result. With both windings attached to the armature-core, however, no effective torque would be developed, as it will readily be seen that each winding or coil would be impelled in an opposite direction. If, however, only one of such windings be made fast to the revolving armature-core while the other is fixed in space, the maximum torque is secured, while the self-induction is reduced to a minimum, since the two windings, as before, will neutralize one another, so far as self-induction is concerned, while the stress due to the field will be transmitted from but one of them to the core. It is not necessary that the two windings should be exactly alike, if only the magnetizing effects shall be approximately equal and opposite.

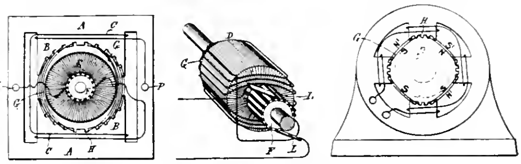
In direct-current motors and generators a somewhat similar disposition of coils to that above described has been employed to neutralize the magnetism imparted by the armature-coils and for the purpose of preventing change of lead; but as we propose to deal only with alternating-current machines we place our coils exactly parallel to the field magnetization and organize them so that they serve as anti-induction rather than anti-magnetization coils and close them upon themselves, so that they will be acted upon inductively by the moving armature-coils and, by the current generated therein, tend, so to speak, to check the rise of magnetism in the armature rather than its ultimate development.

The invention therefore consists in the combination, in a machine of the kind described, with the rotating armature and coil or coils thereon, of a stationary coil or coils closed upon itself or themselves, adapted to produce an effect approximately equal but opposite to that of the coil carried by the armature, whereby the self-induction and consequent retardation in the armature will be neutralized or overcome.

The plan or means by which the invention is carried out is illustrated in the accompaning drawings.

Fig. 1 is an end view of a motor embodying the invention. Fig. 2 is a perspective view of an armature, exhibiting, diagrammatically, the special winding which the invention involves. Fig. 3 is an end view of a multipolar field-magnet with the improvements applied to the same.

In Fig. 1, *A A*, represent the field-core of any ordinary motor; *B B*, the polar projections between which the armature is mounted,



FIGS. 1, 2 AND 3.—SINGLE-PHASE ALTERNATING-CURRENT MOTOR.

and *C C*, the energizing field-coils surrounding such polar projections. *D* is the armature-core, *E* the coils wound thereon, and *F* is the usual commutator. *G* designates the stationary coil. This coil is wound in convolutions parallel to those on the armature and are conveniently contained in recesses or grooves *H*, cut or formed in the faces of the pole-pieces.

The relations of the two armature-coils are better illustrated in Fig. 2. The armature *D* in this case is wound in the usual way, with a conductor laid parallel with its axis in coils connected with the segments of the commutator *F*. The line of commutation is shown by the position of the brushes *L L*, and the stationary coil *G* is shown as surrounding the armature, its convolutions being in planes at right angles to the line of commutation.

In Fig. 1 the armature and field-coils are in series and the stationary coil is closed upon itself. The stationary coil is shown more clearly in Figs. 2 and 3 as having its ends connected together, the coil being thus in closed circuit.

In Fig. 3 the field-core is provided with a number of pole-pieces, being, in fact, a type of multipolar machines. The stationary coils in this case are wound in grooves in adjacent pole-pieces, so as to produce an opposite magnetizing effect upon or in the armature to that of the armature-coils. For example, if the tendency of an armature-coil is to produce a north pole in its core at any given point, as *N*, the corresponding stationary coil will have an equal tendency to setting up at the same point an opposite pole. So, in general, where the armature-coils act to establish poles *N S*, the stationary coils neutralize such action by establishing poles *S' N'*, as indicated in the diagram. The stationary coils, *G*, it will be observed, do not sensibly affect the magnetic conditions of the field, owing to their position relatively thereto; but their magnetizing influence is manifested in the armature-core, where it opposes that of the armature-coils.

In practice the conductors of the supplemental or stationary coil or coils will be bent aside at one or both ends of the armature to permit the latter to be introduced in or withdrawn from the field-magnets, as is indicated in Fig. 1.

This invention is more particularly applicable to and useful with motors; but it may be used to advantage, when the machine is run as a generator, for preventing lagging of the current.

The claims are as follows:

1. The combination with the armature of an alternating-current motor and the energizing-coils wound thereon, of a stationary coil closed upon itself and having its conductors or convolutions substantially parallel to those of the armature-coil, whereby the self-induction of the armature will be neutralized, as set forth.

2. The combination, with the armature of an alternating-current motor having a commutator to which the coils wound on the armature are connected, of a stationary coil closed upon itself and having its conductors or convolutions substantially parallel to those of the armature-coil, whereby the self-induction of the armature will be neutralized, as set forth.

American Electrochemical Society Elections.

To the Editors of Electrical World and Engineer:

Sirs:—In common with most of the directors of the American Electrochemical Society, I signed a petition for a constitutional amendment, making the president, vice-presidents and managers ineligible for re-election. I must, therefore, decline to be a candidate for re-election to the office of vice-president, for which, I am officially informed, I have been nominated.

At the same time, in view of the very handsome vote which my friends have cast for me in nomination for the presidency of the Society, and of the fact that the board of directors are not endorsing any one for that office, I announce myself as a candidate for the presidency.

Ann Arbor, Mich. Henry S. Carhart.

DIGEST OF CURRENT ELECTRICAL LITERATURE.

Dynamos, Motors and Transformers.

Alternators in Parallel.—Bohle.—An abstract of a paper read before the Leeds Section of the (British) Institute of Electrical Engineers, discussing the operation of alternators in parallel. He briefly discusses the methods for quickly damping oscillations which occur; they are either mechanical damping methods of the well-known device of Hutin and Le Blanc or similar methods. If, on account of sufficient fly-wheel masses, the fluctuations of energy supplied to the network are smaller than the fluctuations of energy of the crank effort diagram, damping is useless. But if there are small fly-wheel masses, so that the fluctuation into the network are larger than the fluctuations of energy of the crank effort diagram, damping will give good results. In other words, use damping with multi-crank sets, but not with single-crank sets.—Lond. *Elec. Rev.,* February 5.

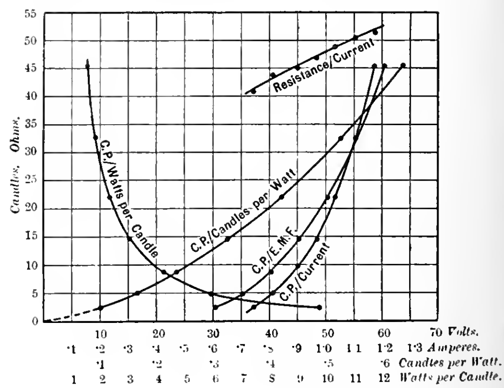
Lights and Lighting.

Osmium Lamp.—Baily.—An article in which the author gives some results obtained with 55-volt, 32-cp lamps, made by the Vienna company which owns the Osmium lamp patents. There are three loops of wire, each anchored at the end, the total length of wire being 40 cm., with a diameter of 0.1 mm. The wire is very hard, and as brittle as glass, with a pale greyish-white surface. The variation between the five lamps tested in candle-power and efficiency was very slight. The average results are given in the adjoining diagram. In general the curves resemble those of the carbon filament lamp, but the agreement is not e :t. The resistance increases with the temperature, while that of carbon between a red heat and a yellow heat slightly diminishes. Therefore, the watts absorbed, as the e.m.f. is raised, increase more rapidly for the osmium than for the carbon lamp. Nevertheless, the increase of candle-power is more rapid in the carbon than in the osmium lamp. Thus it varies as the sixth power approximately in the former, while the curve shown here is of the form cp = 0.0000035 multiplied by the fourth power of the e.m.f. The relation of efficiency (candles per watt) to candle-power for the osmium lamp is given by the equation efficiency = 0.065 multiplied by the 0.62d power of the candle-power, as against 0.028 multiplied by the 0.7th power of the candle-power for a carbon lamp. Thus, the improvement of efficiency is more rapid in the carbon lamp than in the osmium lamp. The important point about the lamp is its efficiency, which at the normal pressure of 55 volts is 1.9 watts per candle. Some favorable results, obtained by Wedding, as to life and maintenance of efficiency, are recorded; they were already noticed in the Digest. The cost of the high efficiency of the osmium lamp is stated to lie mainly in the higher temperature which the metal will stand, but it seems to be a slightly more efficient light radiator than the carbon, especially at lower temperature, although the ratio is probably reversed at higher temperatures. The color may be defined as similar to that of a carbon lamp running at 2.1 watts per candle. It is thought that the lamps should form excellent sec-



OSMIUM LAMP CURVES.

ondary standards of light, because of the whiteness of the light, the small deterioration of the candle-power, and, lastly, because of the smaller variation of candle-power with change of e.m.f., rendering error of adjustment of e.m.f. less serious than in the case of the carbon standard lamp. On this account they should be adjusted to a definite e.m.f., not to a definite current.—Lond. *Elec.,* February 12.

Theatre Lighting.—A fully illustrated description of the new lighting installation of the Drury Lane Theatre, in London. The equipment has been recently brought up to date to minimize danger of fire. The installation is described in detail, especially the switchboard and the regulators for stage lighting.—Lond. *Elec.,* February 12.

Power.

Electricity in Mines.—A reprint in abstract of a report of the (British) Departmental Committee, appointed to consider the use of electricity in mines; also an editorial on the subject. The committee, while refusing to dictate as to which system of generation, transmission and distribution should be employed, clearly exhibits a leaning towards three-phase working. In one instance it is stated that a coal cutter, daily cutting 250 tons of coal, was driven by a three-phase induction motor, and has worked well for some years; coal cutting is the most arduous work in coal mining. Dangers with the use of electricity in mines do exist, but they are much smaller than is generally imagined and accidents usually arise from faulty installations and careless or unskilled handling. The committee emphasizes the fact that no matter what the system may be or how high the voltage employed the whole installation should be considered a source of "potential danger." Except where electric locomotives are employed, or under other very special conditions, the committee do not consider an earthed return advisable. A warning is uttered against the overloading of cables by the addition of numerous subsidiary motors. —Lond. *Elec.,* February 5, 12.

Hoisting in Mines.—HERZFELD.—An illustrated article in which the author says that the sudden variation of load, which is one of the disadvantages of winding work, is felt much less with electric power distribution than with steam driving. In every case where electric driving has been adopted the cost of winding has been considerably reduced, and the larger the generating station from which the supply is obtained, the greater is the saving effected. He discusses the "Koepe wheel" and says that, for the same plant, a Koepe pulley coupled to an electric motor can be of about one-fourth the weight of a drum coupled to a steam engine. He believes that the Koepe pulley system with direct-coupled electric motor will be the system of the future. Some installations of German plants are described.—Lond. *Eng'ing,* February 12.

Electric Power in Ship Yards and Engine Works.—ANDERSON.—A paper read before the Newcastle Section of the (British) Institute of Electrical Engineers. He thinks that a combination of the three-phase system for power and the direct-current, three-wire system for lighting and special power purposes has the greatest advantages. For ordinary use he advocates the employment of the squirrel-cage induction motor. Since the wiring is not complicated nor expensive, squirrel-cage motors should always be used on such machines as punches, shears and beam benders, where the starting gear has sometimes to be placed at a considerable distance from the motor. On the other hand, for such machines as winches and cranes the slip-ring motor is the only one which will prove satisfactory. Details are given on power consumption of three-phase motors driving various machines in Newcastle.—Lond. *Elec. Eng.,* February 12.

Power Equipment of the Cleveland & Southwestern Traction System.—An article on this plant which is the first steam turbine installation for electric railway work in this country. A large portion of the system is provided for by the high-tension alternating-current system and eventually the entire road will be operated along these lines, but at present direct-current transmission is used for a portion of the system. In the main power house the direct-current units, aggregating 1,000 kw, occupy twice the space that the present turbine equipment requires, although the latter is double the capacity, or 2,000 kw. The turbines are of the Westinghouse-Parsons multiple expansion, parallel-flow type. Each system consists of three independent sections, namely, high-pressure cylinder, low-pressure cylinder and generator, the construction being explained in detail. In addition to the ordinary sub-stations located along the line the company has a portable sub-station which has been found very convenient in relieving the excessive load at particular points where there may be some unusual temporary demand for current.—*St. R'y Jour.,* January 30.

Electric Power in a Pianoforte Factory.—A description of the electrical equipment of a large pianoforte factory in London. A special advantage in electric driving in such factories lies in the fact that the manufacture can be carried on in a uniform direction, no transporting to and fro of partly finished parts from one tool to the other being necessary. Direct current at 230 volts is used, there being altogether 19 motors, nearly all totally enclosed (to prevent any danger of fire) and ranging in power from ½ to 26 hp. Some have been adopted for directly driving the various machine tools such as saws, polishing lathes, planing machines, etc. Others serve to drive short lengths of shafting.—Lond. *Elec.,* February 5. A longer illustrated description is given in Lond. *Elec. Eng.,* February.

REFERENCES.

Curtis Turbine.—SAMUELSON.—An abstract of a paper read before the Rugby Engineering Society. Several illustrations, giving comparative views of various turbo-generator sets and comparative elevations of engine-driven and steam turbine sets, and some diagrams showing the effect of different degrees of vacuum and expansion upon the steam consumption are reproduced.—Lond. *Elec.,* February 5.

Steam Meter.—BAYNTUN.—An illustrated description of a meter designed to measure and record the weight or quantity of steam passing through a pipe. By its means the rate at which a boiler is raising or an engine using steam may be read directly off a scale, and, by the addition of a recording drum, continuous record may be kept from which the total weight passed in any given time may be ascertained. The meter is essentially a volume meter.—Lond. *Elec. Rev.,* February 5.

Boiler Room Practice.—EDWARDS.—An article containing valuable suggestions regarding the care of boilers and their accessories.—*Am. Elec.,* February.

TRACTION.

Accumulator, Third-Rail and Three-Phase Traction in Italy.—LANINO.—A long account of the results obtained on four Italian railroads with electric traction. The first road is from Milan to Monza (13 km.), with storage batteries on the cars. The motor car, used on this road, had a weight of 58 tons, of which 20 tons were the weight of the battery (Hensemberger-Planté type) and could develop 100 hp with an average speed of 35 to 40 km. per hour and an acceleration of 2 to 6 cm. per second at the start, one charge of the battery being sufficient for a run of 50 train km. The system was found to meet in general the requirements of normal service, but not those of rush service on holidays, since there was only a limited number of motor cars available. The financial results were good, the cost of operation being 16.25 cents per car km. The energy consumption was 65 watt-hours per ton km. The maintenance of the plates caused an expense of 7 cents per ton km. The cars running on the road from Bologna to San Felice had a weight of 15 tons and could forward 75 passengers; with a battery of 12 tons weight with one charge they could run 100 km. and draw a 15-ton trailer on the first half of the line. The average speed was 45 km. per hour on a road with grades up to 0.3 per cent. The positive battery plates lasted more than 12,000 train km., the negative ones more than 20,000 ton km. The cost of maintenance of the battery was 6.08 cents and the total cost of operation 11.15 cents per train km. Thus the economical and technical results were must better than had been expected. In spite of this the operation with storage batteries was completely discontinued, partly by the influence of some railroad officials and partly because the service was not "elastic" enough to fulfil the requirements of very heavy service at certain hours. On the Milan-Varese-Porto Ceresio road (75 km. of which 60 km. are double-track) the third-rail system with 600-volt direct current is in use, the transmission of power being 12,000-volt three-phase current. The success of this line has been complete, there being no serious accident on account of people coming into contact with the third rail. "This fact is the more remarkable since the third rail, although properly protected from contact, runs through all stations, including a considerable number of tracks in the interior of the hall of the central station in Milan." Attention is called to the fact that in Italian stations the tracks are on the same level as the platform and that passengers have often to pass over the tracks. In very cold winter and in spite of heavy snow falls there was no difficulty with the third rail. The loss of current per km. of road was 0.06 to 0.07 ampere in dry air, and 0.11 to 0.12 ampere in moist air. The fourth road is the Valtellina line, on which 20,000-volt, three-phase currents are used for transmission to transformer sub-stations, which reduce the voltage to 3,000. The motor cars are provided with 3,000-volt, three-phase induction motors and tandem connection is used to get a second speed. This system has also been very successful. The author remarks that there is no competition between the third-rail, direct-current system and the three-phase system. The service on the third-rail road is characterized by many light trains with good acceleration; that on the three-phase road by heavy trains in longer intervals. The first is similar to a street railway; in the latter low first cost of installation and high efficiency are essential conditions. The author believes, however, that the future of electric traction belongs to the series motor.—*Elek. Zeit.,* February 11.

Third-Rail Shoe.—A description of the new third-rail shoe on the Boston Elevated, which differs radically from any other shoe in use on third-rail work. It consists of a soft steel bar, weighing about 5 kg. This bar, which is the portion used for making the contact with the third rail, rests in a hanger at each end and is held down by its own weight and also by a light steel spring, which is constructed to give a downward pressure of about 23 kg., making a total pressure between the shoe and rail of 28 kg. without regard to the motion of the shoe along the rail. When the car moves, however, it tends to bunch the shoe up and compel it to make harder contact with the third rail at one end, depending on the direction in which the car is moving. The life of the shoe is about 21,600 km. A feature of the shoe is that it does not jump at joints.—*St. R'y Jour.*, February 6.

REFERENCES.

Collector for Single-Phase Cars.—An illustrated description of this collector which is manufactured by the Oerlikon Company and consists of curved rod having its convex face in contact with the power wire. The collector can move through an arc of 180°, so that the power wire can be in almost any position. The advantages of the apparatus were noticed recently in the Digest (abstract of Herzog's paper). Two diagrams are given showing the universality of the application.—*St. R'y Jour.*, January 30.

Contact Rail System.—Del Mar.—An illustrated article dealing with the practical problems with which a draftsman has to contend when preparing to lay out a system of contact rails for railways about to be converted from steam to electricity.—*Am. Elec.*, February.

Electrification of a British Railway.—An illustrated article on the electrical equipment of the Tynemouth lines of the Northeastern Railway, a third rail and the Thomson-Houston multiple-unit system being used. The power house will contain two 2,000-kw and two 3,500-kw Parsons turbo-alternators.—Lond. *Elec.*, January 22.

Conneaut & Erie Interurban System.—A description of this line, which is 56 km. in length, and forms the connecting link between Buffalo and Toledo and Detroit. Snow falls quite heavily in this region and the company has the second largest rotary plow in the United States, provided with four axles with four General Electric 100-hp motors on the trucks and a 200-hp motor to drive the fans. The power station contains two 400-kw generators and a booster for 375 volts and 300 amp. Polyphase transmission is not used.—*St. R'y Jour.*, February 6.

Rating of Stations.—Bond.—A paper on the rating of tramway and light railway undertakings. The paper deals mainly with English legal conditions.—Lond. *Elec.*, January 29.

Installations, Systems and Appliances.

British Central Station.—A description of the municipal station of Chesterfield. The direct-current, three-wire system is used. There are two 100-kw and two 200-kw generating sets and a battery of 280 cells with a rated capacity of 60 amp. for 10 hours and 300 amp. for one hour. In the years 1902-3 a total of 208,316 units was sold, the works costs being 1.64 cents per unit sold, and the total cost 2.74 cents. The current is mostly used for lighting, but the demand for motors is increasing, an equivalent of 170 hp being at present connected to the mains.—Lond. *Elec. Times*, February 4.

Wires, Wiring and Conduits.

REFERENCES.

Calculating the Capacity of Overhead Lines and Cables.—Lichtenstein.—The first part of a mathematical article in which the author develops approximate formulas for the capacity of parallel overhead wires for direct-current, single-phase current and three-phase currents, and for concentric two-phase and three-phase cables. The method, used by the author, is a generalization of Kelvin's principle of electric images. On account of its mathematical character, it is impossible to abstract the article briefly.—*Elek. Zeit.*, February 11.

Cable Works.—A fully-illustrated description of the cable works of Pirelli & Co., in Milan, which is stated to be the first firm in Continental Europe to manufacture submarine cables. The works are described under the following headings: Manufacture of washed rubber, spread sheet, cut sheet, calendered sheet, preparation of compound rubber for wires, manufacture of India rubber wires and cables, manufacture of dry-core telephone cables and manufacture of electric light cables.—Lond. *Elec. Rev.*, February 5.

Conduit Work.—Weeks.—An illustrated descriptive article on conduit work. The information is very practical in its nature and many valuable hints are given on conduit installation.—*Am. Elec.*, February.

Electro-Physics and Magnetism.

Evolution of Helium from Radium Bromide.—Dewar and Curie.—An account of observations, quite analogous to those of Ramsay, who observed a change of radium into helium. Some radium bromide weighing 0.4 gram was left for three months in a glass tube, communicating with a small vacuum tube and a mercury manometer. There was a continual slow evolution of gas, but the spectroscope showed nothing but hydrogen and mercury vapor. The same specimen was then taken by Dewar to the Royal Institution, where it was sealed up in a quartz tube and fused, the gases evolved being drawn off and examined with the spectroscope. Nothing appeared to be present except nitrogen. After thoroughly clearing off all the gas the tube was sealed up under the oxyhydrogen flame and sent back to France. About 20 days afterward Deslandres examined the tube with an induction coil, connecting it up by means of two pieces of tin-foil attached to the ends. He found a spectrum, not of nitrogen, but of helium, and that in its entirety, no other lines appearing on the plate even after an exposure of three hours with quartz lenses. The permanent luminosity of the tube only showed a continuous spectrum.—*Comptes Rendus*, January 25; abstracted in Lond. *Elec.*, February 12.

Selenium Cells.—Pfund.—While according to Bidwell the sensitiveness of a selenium cell is due to the presence of selenides in selenium, the present author concludes from a series of experiments that the sensitiveness is due rather to some direct action of light upon the selenium itself. It may be that light in falling upon selenium changes its crystalline character, and that the new modification of selenium is stable only in light, so that it reverts to its original condition when light is cut off.—*Phil. Mag.*, January.

REFERENCES.

Electromagnetic Theory.—Kolacek.—A mathematical note on the ponderomotive forces to which a homogeneous dielectric is subjected in a variable electromagnetic field. The author suggests experiments which would decide the correctness of either Maxwell's or Lorentz's theory.—*Phys. Zeit.*, January 15.

Impedance.—An illustrated didactic article on reactance, impedance, angle of lag and phase difference. All of these phenomena are minutely explained.—*Am. Elec.*, February.

Electro-Chemistry and Batteries.

Electroplating upon Aluminum.—Burgess and Hambüchen.—The principal difficulty in the deposition of a metal coating upon aluminum is as regards its adherence, and this is due to the very thin film of oxide which is always present on an aluminum surface. The authors first clean the aluminum by immersion for a few minutes in a dilute hydrofluoric acid bath where it remains long enough to produce a suitable roughening of the surface. Upon removing the aluminum from this bath it is rinsed in running water and then dipped for a few seconds in a mixture of sulphuric acid and nitric acid, both concentrated. It is then transferred to the zinc plating solution, which is a slightly acidified mixture of zinc and aluminum sulphate, with about 1 per cent. of hydrofluoric acid. Electrolysis is made for about 10 or 15 minutes with a current density of from 10 to 20 amp. per sq. ft. A coating of copper or silver from cyanide solutions may then be applied.—*Electrochem. Ind.*, March.

Electrochemical Equivalent of Silver.—Van Dijk and Kunst.—An account of the results of a redetermination of the electrochemical equivalent of silver. Former researches of various investigators have yielded results varying from 0.011156 (Mascart) to 0.011195 (Pellat and Leduc). The present authors used a tangent galvanometer for determining the strength of the current. Owing to the high degree of accuracy with which the constant of the instrument and the horizontal intensity of the earth's magnetic field and its space and time variations may be determined, this method is well adapted for a laboratory which has been built without iron, and in a place where no vibrations or stray currents in the earth are to be feared. The authors adopted Kohlrausch's bipolar method. The cathodes consisted of platinum, being either cup-shaped or in the form of a cylinder ending in a hemisphere. A silver rod served as an anode. Two voltameters were placed in series in order to insure that no irregularities occurred in the deposition of the silver. The final mean value obtained from 24 measurements was 0.0111818, which the authors believe to be accurate to within one part in 10,000. (The above figures are taken from the Lond. *Elec.* If the electrochemical equivalent is given in divided by 10. The value adopted by the Chicago Electrical Congress is 0.001118 gram per coulomb.)—*Proc. Akad Wet.*, Amsterdam, January 21; abstracted Lond. *Elec.*, February 5.

REFERENCES.

Action of Light on the Formation of Accumulators.—TOMMASI.—An article in which he describes some experiments which show that the negatives of an accumulator form more rapidly in the light than in the dark, and that the positives form more quickly in the dark than in the light, other things being equal. The capacity, however, is found to be practically unchanged.—Lond. *Elec. Rev.*, February 12; *L'Eclairage Elec.*, February 13.

Resistance Furnace.—HERAEUS.—An article in which the author, in form of a reply to Guntz, gives some details of his resistance furnaces for laboratory work, in which around the heating tube very thin platinum foil is wound.—*Jour. Chim. Phys.*, January.

Electrolytic Analysis.—PAWECK.—An illustrated description of some improvements in electrolytic analysis, dealing especially with the use of revolving electrodes.—*Elektrochem. Zeit.*, February.

Progress in Electrochemistry.—KERSHAW.—A summary of the progress in electrochemistry and electrometallurgy in 1903, giving briefly the developments in the different industries.—Lond. *Elec. Rev.*, February 5, 12.

UNITS, MEASUREMENTS AND INSTRUMENTS.

Names of Units.—TEICHMÜLLER.—A long communication in which the writer discusses the advisability of new names of units, proposed at the suggestion of Dr. Kennelly by the American Institute of Electrical Engineers to the next International Electrical Congress. In discussing new names, the question is not whether they are really needed in practice or in commerce, since they may be applied later extensively, even if they appear superfluous at present. He says that many considered the name mho horrible when first proposed, but did not oppose it, since they thought the name would not be used: at present the name mho has become so familiar that opposition would now be fruitless. Concerning the new proposals of the American Institute he thinks that the names do not sound well, and that the lack of harmony, which has been brought into the system by the names of gauss and maxwell, will become worse in future. For, later on, all names of the absolute units may have the prefix ab, but not gauss and maxwell, nor gilbert and oersted. In agreement with Hospitalier, he, therefore, suggests to adopt the following names for absolute units: e.m.f., centimicrovolt; resistance, millimicrohm; current, decaampere; electric quantity, decacoulomb; capacity, kilomegafarad; coefficient of self-induction, millimicrohenry; power, decimicrowatt; energy, decimicrojoule. While these names are rather long, he thinks they are not worse than many names of organic chemistry. He thinks the American Institute is fully justified in wishing names to be adopted for the linear integral of magnetic force and for reluctance. He thinks it is unfair that five English names should be used for units against two each of German and French and one each of American, Italian and Danish scientists. He urges to adopt the name of weber instead of gilbert.—*Elek. Zeit.*, February 4.

Ammeters with Adjustable Sensitiveness.—FEUSSNER.—A long illustrated description of an ammeter which consists of a millivoltmeter with shunt. The millivoltmeter has, besides the ordinary two binding posts, a third one by means of which a small part of the series resistance may be disconnected. The shunt is designed so as to have seven steps. By means of a switch with revolving handle, the instrument may be adjusted so as to give readings according to these seven steps. The lowest sensitiveness corresponds to 1 scale division equal to 1 amp., the highest sensitiveness to 1 scale division equal to 0.01 amp. The switch is operated without any sparking, so that when one takes a reading one may pass from one sensitiveness to another one without interrupting the current or changing any wires. The construction is described in detail.—*Elek. Zeit.*, February 11.

REFERENCE.

Insulation Testing Set.—A brief illustrated description of a very compact insulation testing set made by a British company. It is intended for carrying out insulation tests on the direct-deflection method and consists of a sensitive moving-magnet galvanometer, a resistance of 10,000 ohms and a set of 1/10, 1/100 and 1/1000 galvanometer shunts.—Lond. *Elec.*, January 22.

TELEGRAPHY, TELEPHONY AND SIGNALS.

Telephone Cable Department Accessories.—COAR.—An illustrated article describing a number of articles used in a telephone cable department. A drip pan is shown, which eliminates many of the difficulties attending the boiling-out process. In most boards for making cable forms an arrangement of pegs or nails is used to terminate the different wires. A board which has some advantages over this method is illustrated. Instead of using pegs, holes are bored through the board, which enable the form to be laced more readily and also permit the insulation to be pealed from the wires without altering the shape of the form. A box for holding tags, preparatory to marking the different wires of a cable, which presents some advantages over the old methods of stringing the tags together or hanging them on hooks fixed in a marked board, is also described. A cableman's telephone circuit is shown, and a method for testing out conductors in a cable, which is applicable to both live and dead lines, is described—*Am. Elec.*, February.

Trunk Exchange.—A fully illustrated description of the new trunk exchange of the post-office telephone service, which provides for telephonic communication between London and provincial and continental towns. There are positions for 42 trunk operators. Each switch section is divided into three panels, controlled by two operators. Five trunk circuits terminate on each of the outer panels, which also carry the multiples of the junction circuits serving the minor local exchanges. The junction circuits of the principal local exchanges are multiplied on the middle panel of each section, where they are accessible to either operator. Transfer circuits for interconnecting trunk circuits are provided on each of the trunk panels, as well as foreign, reserve and the usual official circuits. Apparatus is also provided for terminating a number of local subscribers' circuits which are used only for extensions to the trunk system.—Lond. *Elec. Rev.*, February 5, 12.

Railway Signals.—An article on the Hall electrode-gas signalling system, which will soon be introduced on a section of 11 miles of the North Eastern Railway Company, of England. While in European practice the semaphore signal was heretofore worked by an electric motor, carbonic acid gas has now been adopted as motive power. The gas is admitted into cylinders containing pistons attached to the upright rods. The valves controlling the admission of the gas into the cylinders are opened and closed by the armature of an electromagnet, which is energized in the usual way by a local circuit controlled by the relay of the track circuit.—Lond. *Elec. Rev.*, January 22.

Railway Telephones.—An illustrated description of telephones for railway use. Two types are shown, one being an iron box telephone to be attached to the poles along the line and the other being a portable car telephone encased in a wooden box with a leather strap for carrying. This instrument is fitted with a long cord, at the end of which is attached a plug for insertion in jack boxes. These jack boxes may be installed on poles along the line and communication had with the central office by plugging in at these points. The cord is long enough to allow the motorman to leave the instrument in the car.—*St. R'y Jour.*, February 6.

Tramway Signal System.—A description of an electromagnetic signal system using two solenoids for operating the semaphores. When the car enters a block it makes contact with a plate on the trolley wire. This contact closes a circuit operating the main solenoid. The energized solenoid pulls up the semaphore, which is then held in place by a catch. When the car reaches the end of the block, contact is again made through a second plate and current flows to energize the second solenoid. The latter pulls back the catch, thus causing the semaphore to fall back to safety position.—*St. R'y Jour.*, February 6.

MISCELLANEOUS.

Manufacturing Plant.—A fully-illustrated description of shop No. 3 of the Bullock Electric Manufacturing Company.—*Mach'y*, February.

Obituary.—An account, with portrait, of the life and work of W. G. McMillan, the late secretary of the (British) Institution of Electrical Engineers.—Lond. *Elec. Rev.*, February 5.

New Books.

Messungen an Elektrischen Maschinen. By Rudolf Krause. Berlin: Julius Springer. 158 pages, 166 ill. Price, 5 marks.

This is a capital little book on engineering measurements and tests of dynamo machines from an electrotechnical standpoint. Polyphase dynamos receive especially full treatment.

The first chapter is devoted to measuring instruments generally. Their elementary mathematical theory is well outlined from the engineer's viewpoint. The theory of the modern hot-wire voltmeter and ammeter is given here for the first time so far as has come to our notice.

The second chapter considers the electric power measurements of alternating-current generators. The third chapter deals with temperature changes of resistance and their measurement. The fourth chapter deals with measurements of frequency and the fifth with the measurement of insulation and conductor resistances. Magnetic measurements are followed in the sixth chapter and in the seventh tests for efficiency and regulation are considered, also tests for temperature elevation and torque. The eighth chapter relates to the measurement of losses in machines by tests on open circuit. The ninth chapter deals with the measurement of the wave form of voltage and current in alternators. A brief final chapter considers standard tests of machines and their formal tabulation.

The book is an excellent compendium of polyphase tests according to German practice. It does not contain many of the methods that are adopted in other countries. It will be found of much value to students of electric machine testing.

Wireless Telegraphy. By Charles Henry Sewall. New York: D. Van Nostrand Company. 229 pages, 85 illustrations. Price, $2 net.

Mr. Sewall puts forward his admirable book very modestly. It is intended for the general public as well as for the technical student. There is growing up a specialized literature on wireless telegraphy, so that the expert has to, and in fact prefers to, restrict his range of study; but there are many points and much data in this volume that render it an exceedingly useful book to have handy in an electrical library. Not the least interesting part of this nature is the chapter devoted to Mr. Tesla's work. It is the first connected story of the kind on any work of Tesla's, since the book by Martin, issued away back in 1894, before Mr. Tesla had begun to carry out even experimentally the theories and ideas with which he had even then been so daringly profuse as to wireless transmission, not only of intelligence but of actual energy. It may be a close guess that the author had Mr. Tesla's help on this fascinating chapter, which somehow seems to leave the reader "in the air," but is full of deep suggestiveness and is generously illustrated.

Mr. Sewall is certainly liberal and eclectic in his methods, for while he thus takes us up into the ambient wireless air with Tesla, he also plunges us into the depths of the sea with Pupin's coils, as applied to ocean cables. At first the propriety of the juxtaposition is hardly realized, but after all in a comparison of rival methods the matter has its place in such a book, and many will welcome it. They will also welcome many other quite unexpected little plums, not forgetting the portraits of several leaders in the wireless field. Mr. Sewall has been fair, industrious and broad-minded, and we hope his reward will be reaped. The publishers may be congratulated on the handsome shape in which the book is put forth.

Maver's Wireless Telegraphy. By Wm. Maver, Jr. New York: Maver Publishing Company. 216 pages, 123 illustrations. Price, $2.00.

The fact that this book is written by one of the foremost telegraphers of America, whose encyclopædic work on American telegraphy is already a standard, will suffice to insure for it a warm welcome. But Mr. Maver has not merely traded on his reputation and thrown together a haphazard catch-penny volume, to meet the sensational demand of the hour. With his usual thoroughness and clean-cut style, he has taken up the subject in a highly practical manner, soberly and seriously, giving space, it is true, to theory, but going straight for practice. It is here that Mr. Maver excels. He can himself theorize as well as do justice to the philosophies of others, but he is at his best when discussing and dissecting circuits and apparatus. In fact, much encouragement is to be derived from the issuance of such a book. We realize of a sudden that, beset as it may be by a dense mass of ill-digested theory and of loose statements that explain nothing, a new art is upon us and is being legitimately practiced.

Chiefly to be commended in addition to the lucid descriptions are the excellent diagrams and drawings. We have an idea that Mr. Maver likes to work a thing out thus on paper for his own guidance and comprehension; and he succeeds just as well with wireless conditions as he has done in the past with metallic circuits and the apparatus on which he spent his own life as a telegrapher. Another point is that all the various plans, schemes, inventions and apparatus now struggling for supremacy are set forth in a strong, dry, white light, with full impartiality. The index is most complete and praiseworthy, and we like also the business-like closing chapter of practical suggestions on wireless signalling. We would recommend every telegrapher to read this book, but it will find a large public also outside the telegraphic ranks.

Elemente der Elektrotechnik. By Moriz Kohn. Leipsic and Vienna: Franz Deuticke. 108 pages, 121 illustrations. Price, 2.50 marks unbound.

This little book contains a series of ten lectures given before a mining association at Pilsen. The conditions under which the course was held prohibited mathematical treatment and required all the subjects to be selected and presented with reference to practical electrical work. Ordinarily, these requirements would have rendered the work of an author so commonplace and colorless that there would have been no reasonable motive for publication except for circulation among that class of workmen for whom they were designed and delivered.

The present book, however, has a real interest for the reader. Its author is a professor in one of the excellent national industrial schools, which are now such a prominent factor in German education. He has come to his task of simplification with a firm grasp on exact technical knowledge; and, moreover, he has accommodated his subject to a class for whom he must select only the vital elements of technology, and bring them within the comprehension of those unskilled in mathematics. This will indicate the scope of the book and suggest its usefulness.

The lectures as a whole are admirable in the selection of subjects and topics, and the treatment is clear and concise. The matter of the book would have gained had it been less descriptive, and been emphasized by more frequent numerical examples. The illustrations are wholly diagrammatic, and they are exceptionally clear and well conceived. One illustration, in particular, is novel and more clever than the usual cumbersome mechanical analogue. The displacement of phase between two functions is illustrated by a device of two pistons in tandem with a spring connection between them. The frictional resistance of the head piston of the diagrammatic tandem engine perfectly represents the lag of the current in an alternating circuit. A surprising statement is made regarding the efficiency of large direct-current dynamos, where the value is given between 70 and 90 per cent.

The subjects discussed are the direct and alternating-current dynamo, the transformer, rotary converter and the accumulator. To those readers who are familiar with that excellent class of German works of which Keck's "Graphische Statik" may be instanced as a representative, this book by Kohn needs no further commendation than to include it in the number.

Radium in Cancer Treatment.

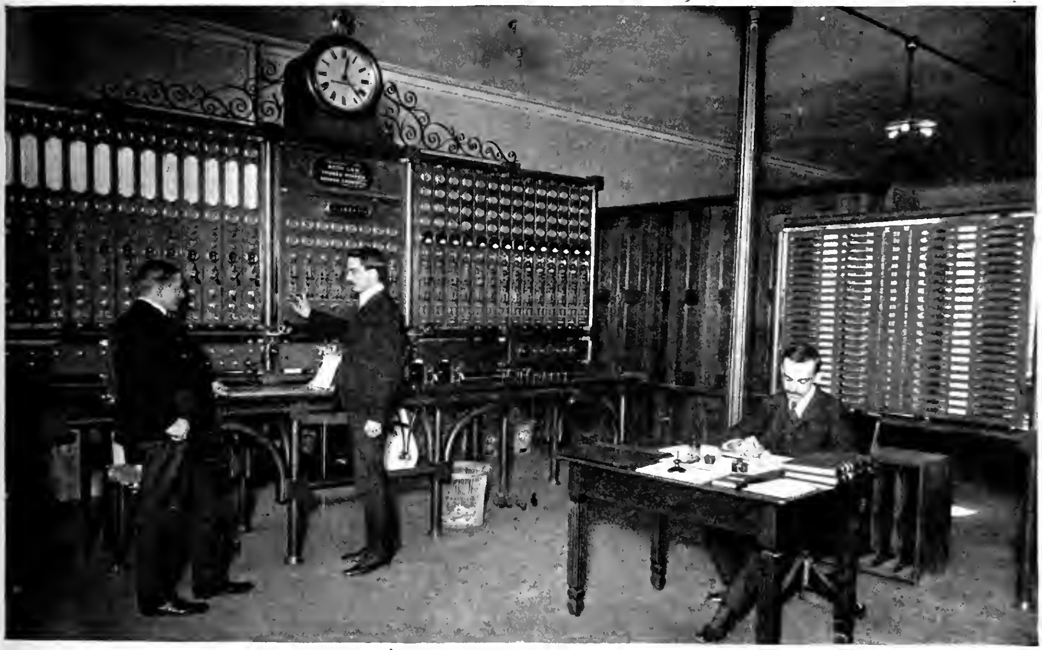
By advices from London it appears that both Dr. G. H. Plimmer, who has returned from a study of radium cures under the care of Prof. Etner, in Vienna, and Dr. Snow, of the Brompton Cancer Hospital, are very sceptical as to its results, the latter characterizing cancer as remaining "the darkest Africa on the map of medicine."

Dr. Snow, who has had vast experience in the treatment of cancer, in what probably is the last address he will deliver at Brompton Cancer Hospital, the other day pointed out that cancer is not one, but is constituted of many diseases. He said that the radium treatment had proved exceedingly disappointing and, in fact, it might now be dismissed from the sphere of potential cancer cures. At Brompton Hospital, he added, they had studied cancer as it had been studied nowhere else in the world. They had sought to investigate it from every conceivable point of view. They had labored by every means in their power to substitute for the mass of chaotic confusion and the traditional fallacy which had hitherto prevailed a genuine cancer science as a sure foundation for all future research; but in this attempt they had utterly and miserably failed.

Unique Fire Alarm Switchboard on Staten Island, N. Y.

An improvement in telegraph switchboard construction has lately made its appearance in the shape of a new board built for the fire alarm system of the New York fire department, Borough of Richmond, New Brighton, Staten Island. The board is constructed of non-combustible material and embodies all the latest and most desirable points to insure prompt results and absolutely sure and reliable working.

The new board is so constructed that the only part liable to combustion is the insulation on the wire, of which there is very little in evidence, omitting the magnet wire on the relays and the rubber knobs on the keys. The entire board is built of a frame of heavy steel tube. The method of construction is that each section of tubing is threaded right and left hand and is screwed into the fittings in such a manner that it may be at any time dismantled and moved to another location should it be desired. All panels and counters are of slate 1¼ in. in thickness. The switchboard is arranged for the accommodation of 14 box circuits and 8 gong circuits. All the apparatus applicable to each circuit is mounted upon a separate panel. These panels are removable without disturbing the other parts of the board. This in itself is a step in the right direction for one reason that in case of trouble arising in the operation of a fire alarm system it is of the utmost importance to be able to repair it in the shortest possible time.



Fire Alarm Switchboard at New Brighton, Staten Island.

The system adopted in the New Brighton board for announcing the circuits is simple and is as follows: Connected in each circuit panel is an annunciator consisting of a bull's eye of ground glass on which the number of the circuit is painted. To the rear of this is a 4-cp incandescent lamp, which lights up in case of the circuit opening, thereby visibly throwing up the number of the circuit.

Another novel feature is the arrangement of the relays. All relays are made on the same general principle and are non-combustible. They are mounted on the back of the panels, the working points of the armatures protruding through to the front. All circuits are provided with jacks similar to those employed in the telephone systems, so that by the introduction of a plug it is possible for the telephone operator to connect any of the circuits, thereby enabling him to hold conversation with men on the line who may go to any box on the circuit and call up the central office. It is possible to hold conversation over these telephones during signalling transmission from a box.

One of the principal features in connection with the board are the test panels for each circuit to be seen on the right of the switchboard. Each circuit has one test panel upon which is mounted an ammeter, transfer battery switch, pole changer and bridge. The ammeter denotes at all times the strength and direction of the current on the wire. The pole changer enables the operator, by the simple moving of a key to throw on a battery in case the main battery becomes inoperative. The bridge is arranged so that the operator by the movement of plugs similar to those in use in a Wheatstone bridge can change the polarity of the current and make any tests promptly. In addition to these test panels a novelty has been introduced on one of the lower panels, which is certainly a time-saving device so far as testing for cross lines is concerned. Heretofore it has been the practice to move a plug or a switch individually on each circuit, for the purpose of testing for crosses, thereby consuming a considerable amount of time; and in large stations where the business is somewhat heavy, the pursuing of such method has made it possible to lose an alarm. This is overcome in the New Brighton board by each circuit being connected to a dead spring point. These points are arranged in a circle and are covered by a plate which is capable of being pushed into contact with all the points except one, a knotch or section sufficiently large to miss making contact being left in the plate, thereby enabling the operator, by the simple operation of pushing the plate to make the necessary test in a few seconds instead of one or two minutes.

Another unique departure embodied in the new system is the multiple pen register for the reception of all signals transmitted. This register is so constructed that all springs, adjustments, pens and ink rolls are independent and easily reached by the insertion of the hand in front of the register. Each pen has an independent ink roll. With a solid ink roll the whole affair has to be taken apart should one pen get out of order.

Yet another new feature of the Staten Island system is that all the wiring and connections are in full view of the operators. Provision has also been made so that during the transmission from a fire alarm box it is at the option of the operator, by the movement of a switch, to throw in repeating apparatus that will transmit automatically gram per coluomb all the above figures for the equivalent are to be direct from the box to the gong or fire house circuits. This is not as a rule depended upon, but is used only in exceptional cases, for the reason that should an error occur it will be transmitted, and the principle of all manual central stations is that mistakes of this kind cannot take place.

The switchboard was designed by Mr. Henry E. Vineing, the electrical engineer of the New York fire department. It was built by Foote, Pierson & Co., 82-84 Fulton Street, New York City.

English Form of Continuous Current Prepayment Meter.

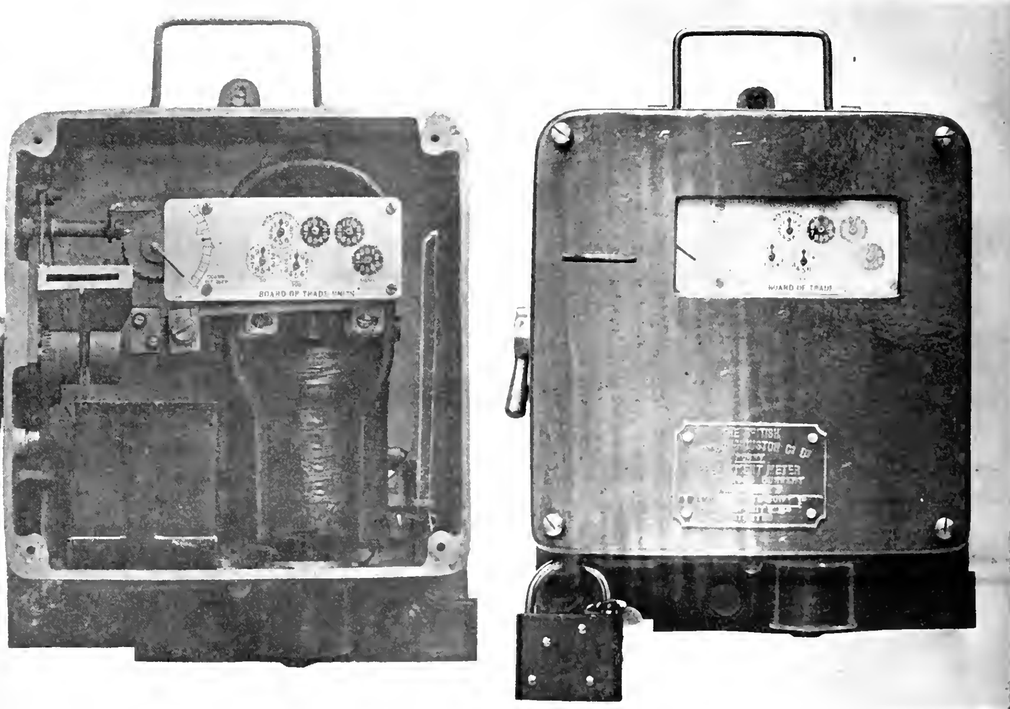
The success of the prepayment gas meter has been generally accepted as indicating that a large sphere of usefulness exists for prepayment electrical meters. The prepayment meter possesses several advantages, among which may be mentioned the avoidance of the perpetual trouble of writing for accounts to be settled, and the reduction of bad debts to a minimum. To the user it offers a great inducement in so far that small payments extending over a protracted period can be made. The British Thomson-Houston Co. has achieved success in the development of a prepayment meter which it is now prepared to offer, for use on continuous current circuits.

This meter consists essentially of two parts—the electrical meter proper, and the mechanical prepayment mechanism, a general idea of which can be obtained from Figs. 1 and 2.

Both the meter and prepayment mechanism are contained within a strong cast aluminum dust-proof case, which is of neat appearance, and occupies a space of only 8⅜ x 10½ x 5 inches deep. It is so constructed that by the removal of the cover, which is held in place by four sealing screws, easy access to all parts of the meter and mechanism is obtained. A window is fitted to the cover, through which both the meter dial and coin indicator are visible. The meter dial registers the total number of units consumed and can be used as a check on the coins deposited, while the coin indicator shows the number of coins still to the credit of the consumer. The terminal box is situated at the bottom of the meter, and has a separate cover, held in place by a small cap covering the commutator, brush gear, and jewel screw, the arrangement being such that they can be sealed independently from the other parts of the meter. A till capable of containing 120 coins—pennies in England—is provided to hold the money deposited in the meter, which may be removed by opening the door at the bottom of the meter. This door can be secured either by a seal or padlock as desired.

The switch is of the single-pole, quick-break, knife-blade type. It is designed to open circuits carrying current up to the amount of the maximum overload allowable for the largest meter to which the device is used. The closing and retaining mechanism of the switch is positive in its action and both strong and simple in construction.

To operate the meter, a coin of the correct denomination is put into the slot provided, and the handle at the left hand side of the meter turned to its full up position, and then returned to its down position. This movement closes the switch and moves the coin indicator hand one division. Successive coins to the number of ten may be put into the meter at one time. At each insertion the indicator hand moves forward one division, and as the consumer uses the current, this hand will gradually travel back to zero, on reaching which the switch opens automatically. Additional coins can be inserted at any time previous to the consumption of the last coin, and so long as the indicator shows there is a coin or fraction of a coin to the credit of the customer the switch will not be opened. Hence by always inserting a coin before the indicator reaches zero, the light will never be switched off.



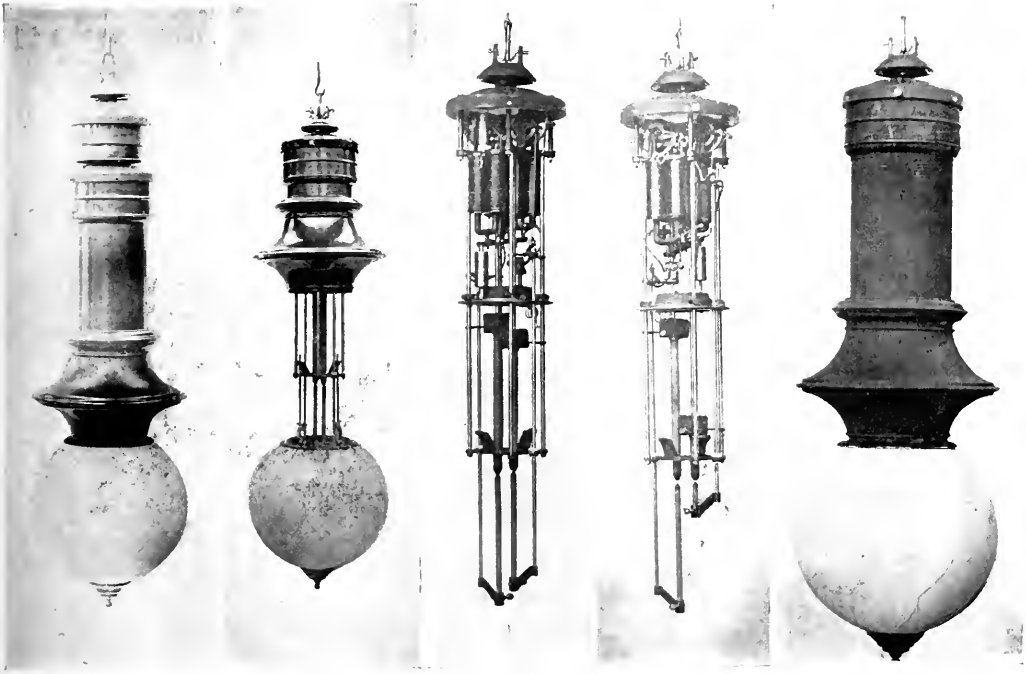
FIGS. 1 AND 2.—CONTINUOUS-CURRENT PREPAYMENT METER.

A prepayment meter must be constructed in such a way as to render cheating impossible, as should it be possible to tamper with the instrument in any way it is evident that it would be worse than useless. In view of this fact, the B.T.H. prepayment meter is made proof against any attempt to obtain current by unfair means.

These prepayment meters are manufactured in 2, 3 and 5 ampere sizes for any required voltage, and may be operated with one penny, sixpenny or one shilling coins as desired. The rate of payment chosen can be easily changed at any later date without having to recalibrate the meter. Special care has been taken to use only the best insulating material possible. This enables the meters to be subjected to an insulation test of 1,000 volts alternating.

Open Arc Lamps in England.

Open arc lamps still appear to enjoy a vogue abroad, and new ones are still introduced there. The British Thomson-Houston Co., Ltd., has designed, and is now manufacturing at its Rugby Works, a 10-amp., open arc, continuous-current focusing lamp. The brake wheel and feeding mechanism are of novel design. The wheel is made on the toggle principle and is very positive in its action, while friction losses are kept at a very low figure. The casing, made of solid copper, with a black oxidized finish, is constructed in two parts which slide over one another. It is supported at the top on bayonet catches, and by removing one thumb screw the upper portion can be lowered, exposing the entire mechanism for inspection or minor repairs. For trimming, the lower portion is raised, and the lamp can be trimmed by lowering the globe only 9 inches.



FIGS. 1, 2, 3, 4 AND 5.—ENGLISH OPEN ARC LAMPS.

When operating two or more lamps in series, it is necessary to have some means of adjustment in order to keep them burning with equal arc voltage. In the B.T.H. lamp this adjustment is made by shunting the series magnets with a high-resistance adjustable coil. The adjustment can be made without turning off the lamp, and much closer regulation can be secured than with a mechanical adjustment.

All parts of the lamp are made by machinery and are entirely interchangeable. No fitting is done when the lamp is assembled, and parts are designed to work together, without being so accurately fitted that their operation would be affected by the dust and dirt which always work into the parts of an arc lamp.

The lamp is so insulated that, when the casing is on, no external part is in connection with the circuit. All the interior insulation is of mica or lava, and the insulation of each lamp is tested at 1,500 volts alternating current applied for 30 seconds. The lamp has a self-contained automatic cutout, and is supplied with or without substitutional resistance as required. External line resistances are used depending upon the line voltage and the number of lamps in series. These line resistances can be supplied for mounting either on a wall or inside of the pole base, and can be made weatherproof when required. The lamp, plain, without substitutional resistance, and with globe in place, measures 51 inches in length, and weighs with globe and casing 53¼ pounds.

An Automatic Mailing Machine.

To take stacks of newspapers, magazines, catalogues or periodicals as they come from the printing press, and to fold, wrap, seal and address them individually is the office of the Agnew auto-mailing machine illustrated herewith. All this is accomplished at the rate

FIG. 1.—MAILING MACHINE.

of from three to five thousand an hour, obviously several times faster than it could be done by hand. In fact, it is claimed that one machine will replace twelve persons, and accomplish the work with greater neatness and less liability to errors, and with less skilled attendance, one man being all that is required.

The operator standing on the side of the machine shown in Fig. 1 works in front of the elevator or conveyor, refilling the shelves as fast as they are emptied, with bunches of the papers or magazines just as they are taken from the press. The construction of the elevator is clearly shown in the cut. It consists of two sets of moving shelves carried, perpendicularly to their direction of travel, by endless chains and arranged to run at the same speed, but in opposite rotation, so that contiguous shelves register with one another. Its action is intermittent, and under electrical control, which maintains the top of the pile at a fixed height. At each cycle of the machine little pneumatic suckers come down on the uppermost paper and, with a combined lifting and pulling movement, start it far enough into the machine to be taken along by a horizontal belt conveyor. Simultaneously at the opposite side of the machine wrapping paper drawn from a continuous roll is introduced under the periodical and cut off the required length.

When the paper and its wrapper have reached a definite position

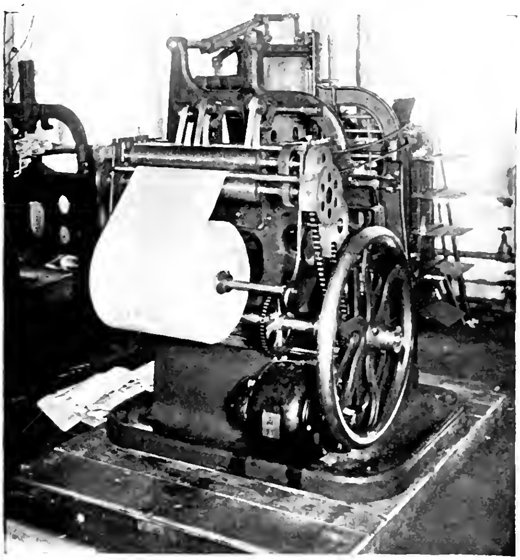


FIG. 2.—MAILING MACHINE.

a vertical blade descends, creasing them through the middle and carrying them down between a set of steel rolls. The vertical blade then returns to its upper position and a horizontal blade folds them again and carries them to a basket or receiver. The wrapper is not entirely under the paper when folded with it, consequently only part of it goes into the inside with the operation of folding. It is sufficient, however, to prevent the wrapper from sliding off the paper later on, and the extra amount projecting on the outside forms the flap. This is gummed by a roller covered with a solution of dextrine, and is pressed down by another roller as the package passes out of the machine. On the shelf at the side of the machine just before being discharged it pauses long enough to receive an impression through a stencil, giving it its individual address.

The perforated stencils for the addressing are arranged to replace one another successively at each cycle of operations. These may be previously assorted by towns or States, thus eliminating the necessity of distributing the mail afterward. For instance, all of a certain group may be run through at a time and discharged into one mail bag, another being in readiness to be moved up to receive those belonging to the next group and so on.

One motor mounted against the side of the machine at the rear, as shown in Fig. 2, provides the power with one reduction through a spur gear and pinion. It is noticeably out of the way and fortunately located where it is protected by the fly-wheel. The motor is of the Crocker-Wheeler make, of a semi-enclosed type, and of 1-hp size, which shows that the cost of running is not very great.

The machine is positively driven at all points by chains or gear connections, so that there is no chance for slipping and causing a loss of co-operation between the different parts. Furthermore, there is an electrical device to open the motor circuit automatically and stop the machine if any interruption in the regular operation occurs, such for example as when a paper fails to feed, or a wrapper is not in place, or when the stack of stencils is exhausted.

The entire machine occupies a floor space of about 4 x 5 ft., has an overall height of 76 in. and weighs about 2,000 pounds when equipped with a Crocker-Wheeler motor, as shown.

Latest Types of "C & C" Dynamos and Motors.

After over two years spent in preliminary work, the C & C Electric Co., of New York, with works at Garwood, N. J., is placing on the market its new line of "type 'S'" direct-current dynamos and motors. The C & C Co., as most of our readers doubtless know, is a pioneer manufacturer of direct-current motors, its experience

FIG. 1.—OPEN TYPE FLOOR PATTERN.

covering a period of over 16 years, during which time it has been exclusively engaged in the manufacture of dynamos and motors for industrial purposes. Its aim in designing the type "S" machine has been to produce a motor or a dynamo of artistic and attractive design, pleasing appearance, minimum weight, compact and symmetrical, and adaptable to almost any class of service. It also aimed at a machine which would be of the highest efficiency, and would withstand unusually heavy overloads without sparking, and with a much lower temperature rise than has heretofore been the case. The apparatus is built in all the standard sizes from 2 to 30 hp inclusive, for

FIG. 2.—ENCLOSED TYPE FLOOR PATTERN.

slow and moderate speed, and expects before long to have ready an entire line from ¾ to 75 hp inclusive.

The machines are made in the open, semi-enclosed and entirely enclosed types. The open-type, floor-pattern machine is illustrated in Fig. 1; the enclosed-type, floor-pattern machine in Fig. 2. Both these illustrations give a good idea of the symmetrical and pleasing appearance of the machine. The machines are furnished in the floor, ceiling or wall (see Fig. 3) horizontal patterns and in the vertical pattern. The motors are well adapted for mounting upon machine tools or machines of almost any description, for direct connection or chain drive. The machines are all of the four-pole type. The magnet frames are of soft homogeneous cast-steel, as are the brackets or feet, and the pole-pieces, which are cast as part of the magnet frame. The pole-tips or shoes are of the same material, and secured

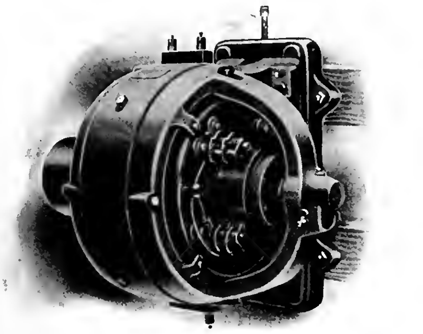

FIG. 3.—VERTICAL PATTERN.

to the pole-pieces by means of external bolts. The bearing-brackets are of cast-iron and carry self-oiling and self-aligning bearings of generous dimensions. A frame-ring is cast as part of each of the brackets, and this ring carries lugs between which the cast-iron brush-ring is supported. The brush-holders are of the well-known "C & C" "reaction" type and are secured to brass pins carried by the insulated brush-rings. This form of support of the brush rigging assures absolute stability and non-vibration of the brushes. The field coils are wound on metal bobbins of novel construction and are

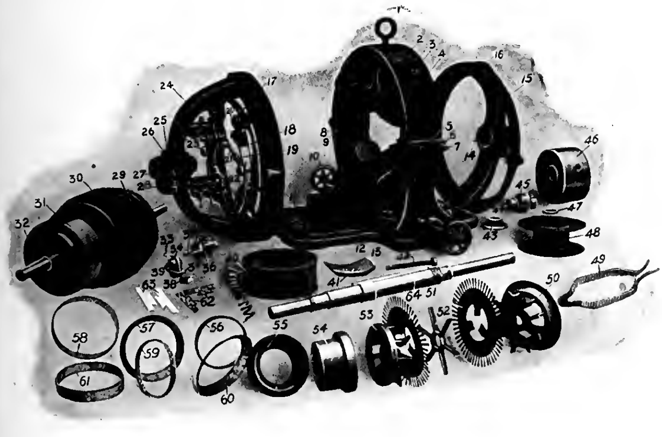

FIG. 4.—COMPONENT PARTS OF MACHINE.

readily removable. The armature is of the hollow drum type. The insulated laminæ forming the core have three openings punched therein around the shaft hole for ventilating purposes, and a spacing spider is placed in the centre of the core for the purpose of forming air ducts connecting with the three channels adjacent to the shaft. Form-wound coils are laid in the armature slots and are retained therein by means of hard wood wedges driven between notches in the teeth of the armature core; consequently no band wires are used for retaining the coils in position. The commutator is of unusually large diameter and face, and is composed of hard drawn copper bars insulated with mica, assembled in a heavy cast-iron shell, mounted on the armature spider.

The C & C Company states that after a continuous run of 24 hours at full load, no part of the machine will show a temperature rise of over 30° C. by thermometer. It also makes other unusual guarantees. This unusually low temperature increase is accounted for by the novel construction of the armature. The armature laminæ spacers, back-plate and end-plate, as well as the commutator itself, are so designed that their several parts radiating from the shaft act as the vanes of a fan, and when the armature is in motion a powerful draught is created. The cool air is taken in through the commutator shell, and part of it is forced through the ventilating ducts of the armature up against the pole-pieces and fields; the remainder through the back of the armature; thus cooling the whole machine. The construction of the armature, as well as all the component parts of the "type 'S'" machine, are well shown in Fig. 4.

"Core" Transformers.

A new line of transformers has recently been manufactured and put upon the market by Messrs. Hornberger and Irwin, who have been identified with the development of alternating-current apparatus from the outset, and who have organized the Crawfordsville Electric Company, of Crawfordsville, Ind., for the purpose of producing apparatus of a standard character in this field of work. Based upon their familiarity with the subject and their experience, they have selected the core type of transformer for manufacture in preference to the shell type, and while admitting that in core type transformers, as ordinarily known, sundry disadvantages appear, they claim that they have overcome the points of objection as to length of core and excessive temperature. In all but the smaller sizes they employ multi-coil construction.

The Crawfordsville Electric Company, as just intimated, builds transformers in the smaller and intermediate sizes, such as are generally used by central stations, but it also builds those of the larger size and heaviest duty, and hence has found it advisable to provide a separate case design for each of the different classes. Their design for sizes up to 15 kw consists of a simple cast-iron case arranged for the use of oil and equipped with steel hangers in the usual manner. For convenience in hanging the smaller sizes they use the well-known suspension hook devised by one of the members of the company.

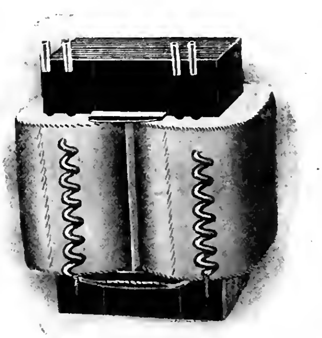

FIG. 1.—"CORE" TRANSFORMER.

The cable terminals are brought out from the case through heavy porcelain bushings securely cemented in place with a compound which prevents effectually the entrance of rain or moisture. All cable connections are made permanently and no connecting block is used inside the case.

For sizes from 20 kw up to 100 kw, inclusive, the case is made with a cast-iron base and cover and with a body of substantial sheet steel. While the sheet-steel case is superior to a cast case and is more expensive to build, the weight is greatly reduced. As a comparison, it may be mentioned that the 50-kw Crawfordsville case complete weighs only 350 pounds, whereas the cast-iron case of a well-known type of the same size weighs over 800 pounds.

For sizes larger than 100 kw the case design is made for foundation support only, on account of the heavy weight, and is so arranged that it can be adjusted to either oil, air-blast or water circulation. The construction is massive, in keeping with the heavy duty for which it has been designed, such as street railway work or long-distance high-voltage performance. The transformers of this magnitude are designed for any frequency from 25 upwards, for any voltage, and for single or polyphase circuits. In sizes of this type

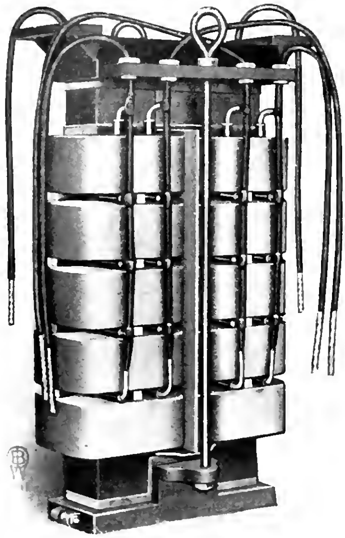

FIG. 2.—MULTI-COIL TRANSFORMER.

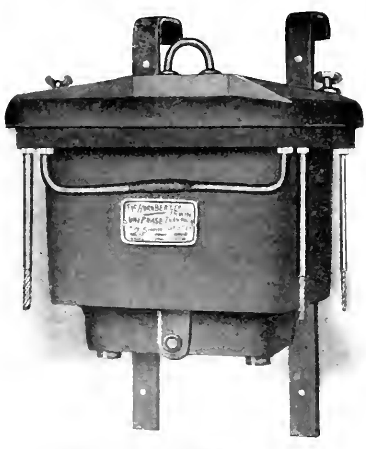
the multi-coil construction is used, the complete transformer being made up of many coils, each having the required number of ratio turns within itself, and all coils being then joined in multiple to the terminals; so that a possible disablement of one coil does not mean that the entire transformer must be replaced or the terminal voltage lowered.

In these "H. I." transformers, as they are known, the cross-section of copper allowed is liberal, and the copper used is electrolytic.



[illegible] TRANSFORMER COMPLETE.

Owing to the multi-coil construction used, cross connection of coils is unnecessary in order to maintain the equal voltage on each side of the neutral wire for three-wire distribution. Ample allowance of copper has also been provided for the increased amount of current required in the operation of inductive apparatus of low power factor. Special attention has been given also to questions of insulation, and mica insulation is used throughout in the construction of the coils, reducing to a minimum the liability or tendency to break down. An improved porcelain fuse box is furnished with broad electrical contacts and liberal copper parts, as well as a long fuse which will break the circuit in every case without injury, ample vent being provided for the escape of gases. The use of oil is recommended, especially in the larger sizes, but the company's guarantee requires that the oil used in the transformers shall be furnished by the company itself. All transformers are tested before shipment under a break-down voltage of 10,000 volts between primary and secondary windings and between the windings and the core. With the multi-coil core type construction and the low densities secured, together with the special steel employed, "ageing" is regarded as impossible, when the apparatus is operated in accordance with its design and purpose; but the company stands ready to replace any transformer showing an appreciable increase of core losses.

Englarging the Field for Unwired Clusters.

The "wireless" clusters made by the Benjamin Electric Manufacturing Company of Chicago are becoming such a staple electrical article that it will be of general interest to state that the company has recently brought out a shade holder which makes it possible to

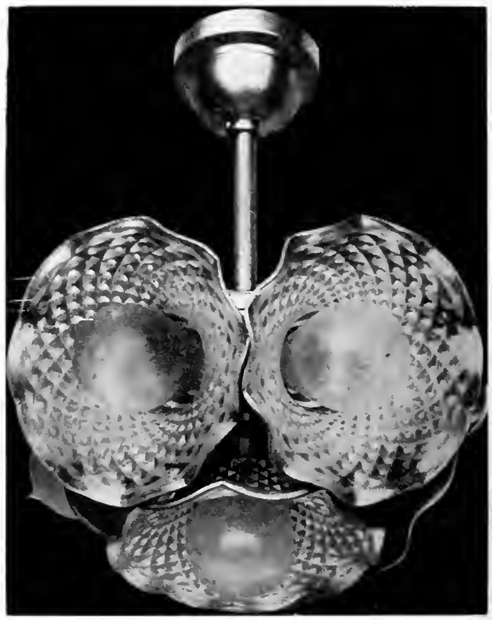


FIG. 1.—CLUSTER WITH INDIVIDUAL SHADES.

place an individual shade on each lamp in a cluster, as shown in Fig. 1. This shade holder fits under the lamp receptacle bushing of any Benjamin wireless cluster. A fixture with a cluster of shaded

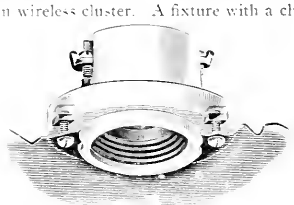

FIG. 2.—RECEPTACLE FOR LARGE GROUPS.

lamps of this kind is pleasing in its simplicity and will materially add to the possible uses of the wireless clusters.

In Fig. 2 is shown a new lamp receptacle, by which the company is enabled to put together easily large clusters of any desired number of lights.

The Reeves Vertical Cross-compound Engine.

Any improvements that add to economy, efficiency and convenient handling of a steam engine, particularly when of a nature that lessens personal attention and assures constant operation, are always of interest, and below are briefly described some of these features as embodied in the Reeves engines.

The design of these engines permits of the development of great power within very small floor space and provides for easy access and adjustment of all parts. In the engine shown in Fig. 1 the cylinder dimensions are 10½ in. and 24 in. x 14 in. stroke; the shaft is 6½ in. in diameter and is provided with three bearings, the outside ones being 11 in. and center one 10 in. long, all the parts so proportioned as to assure a perfectly balanced machine.

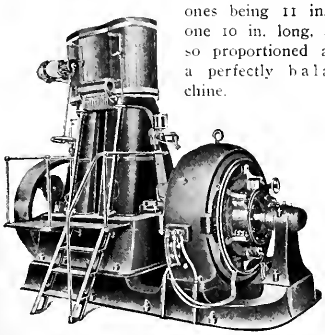

FIG. 1.—CROSS-COMPOUND ENGINE.

In the cross-section, Fig. 2, the high-pressure piston is about to start on its downward stroke, and the low pressure on its upward stroke. The admission valve is moving upward, admitting steam on the top of the high-pressure piston and across through the connecting port, *B*, and around the head of the main valve. At the same time the main or center valve is moving downward, admitting steam under the low-pressure piston. This is the exhaust steam from the previous stroke of the high-pressure piston, which passes through the port, *B*, around the neck of the main valve and through port *C* into the bottom of the low-pressure cylinder.

When the pistons have moved about three-eighths of their stroke the admission port has been opened and the admission valve returned to point of cut-off. The main or center valve is now moving upward and finally closes port *C*. At this point compression commences in the high-pressure cylinder and continues until the main valve opens the port, *C*, again; meanwhile the main valve closed the upper port and compression took place in the low-pressure cylinder.

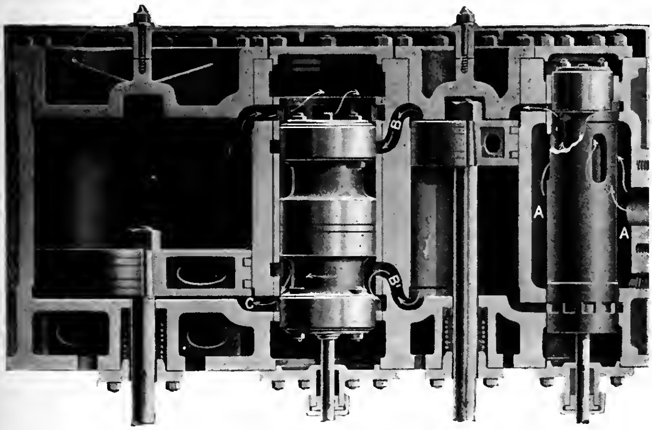

FIG. 2.—CROSS-SECTIONAL VIEW OF ENGINE CYLINDERS.

The steam distribution gives practically an equal division of work in the high and low-pressure cylinders and there being no receiver employed, losses from free expansion and condensation are obviated. The engines are so designed that either cylinder can be used, independently of the other, should necessity require.

The chamber, *A*, around the sleeve in which the admission valve works, acts as a separator and is drained, as can be seen, at the extreme lower end. The sleeve receives the direct impact of the steam instead of the valve; the latter is absolutely balanced, as all its exposed surfaces are under constant uniform pressure. Each of the three openings in the sleeve are larger than the steam pipe, and the steam is, therefore, not wire-drawn in passing to the cavity inside the sleeve.

The cubical capacity of chamber *A*, together with space inside of sleeve, is greater than the amount of steam the high-pressure cylinder can take, up to three-fourths cut-off; as a result, the cards show remarkable steam lines, the actual difference between the initial cylinder pressure and pipe line pressure being extremely small. The space formed by the separator acts as a bank or storage from which the engine draws its supply of steam.

The separator being close to the high-pressure cylinder, acts also to a degree as a superheater; thus instead, as in other separators, being a source of loss, it is here a direct gain, it is evident that any heat it may lose must be taken up by the cylinder. There is no repassing of steam over the same surfaces, which is, in itself, a guarantee of economy. The low cylinder heads are cast integral with the cylinders, which reduces the number of joints to keep tight.

The piston valves employed assure practically constant economy, as they can be easily adjusted (each end independently of the other), and made steam tight without removing them from their seats, and while steam is on the engine.

Referring to the governor, the holes for the shaft and governor pin are bored at the same setting, thereby assuring perfect alignment; then a hard cast-iron bushing, which has been carefully reamed and ground, is pressed into the cavity that is to carry the pin. Into this bushing is introduced a carefully finished gun metal sleeve, constructed with connected lubricating grooves on the inside and outside, around and lengthwise, and by means of which the lubricant, which is supplied by force feed grease cups, is carried to all bearing surfaces.

The governor is attached to the wheel by inserting the pin through the gun metal sleeve. The shoulder on the bar will face the finished surface on the back of the wheel, and the end of the pin will come flush with the face of the sleeve on the front and be held in place by the cap, shown in cut. Referring to the pawl on the cap, and the teeth that are cut into the rim of the sleeve, it will be seen that when the cap is in place it must move with the pin since it is securely held by a dowel and stud bolt.

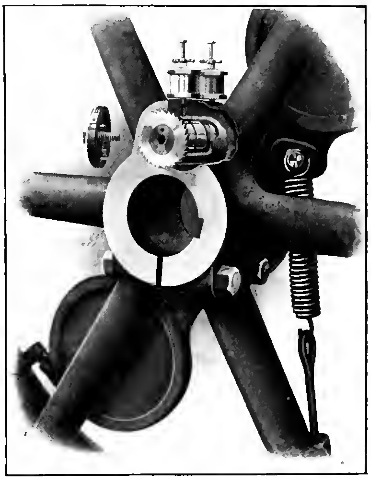

FIG. 3.—THE GOVERNOR.

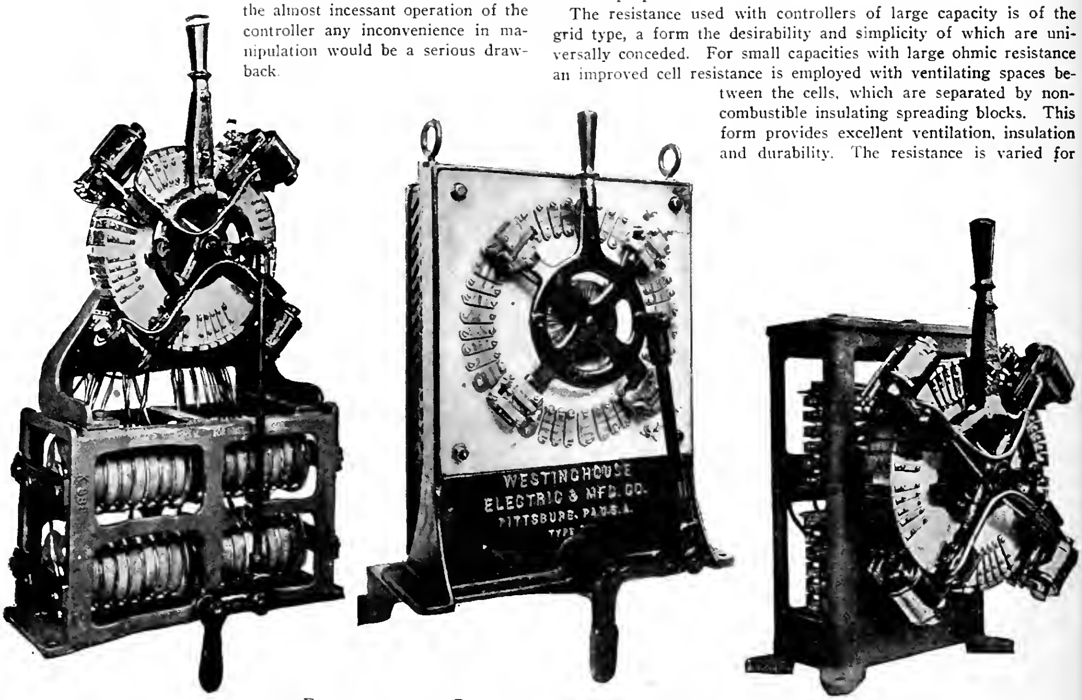
When the governor arm moves away from the stop on the rim of the wheel—as it is sure to do when the engine is started or whenever there is any material change in load—the pawl on the cap will pick up a tooth and turn the sleeve a short distance (always in the same direction); when the arm moves back another tooth will be engaged and the operation repeated, thereby presenting continuously to the pin a freshly lubricated and practically new bearing surface. This insures constant lubrication and practically perfect continuous regulation. Any wear that may occur takes place on the revolving sleeve, and this being interchangeable can be replaced, when necessary, in a very few minutes.

Regulating and Reversing Controllers.

Controllers for motors used upon cranes and in other places where frequent stops and reversals are necessary must have unusual sturdiness, in order to withstand the strain and wear of constant motion. They must also be simple and positive in action in order to give perfect control of the motor, both in speed and direction of rotation, and with the fewest possible movements of the handle, for with the almost incessant operation of the controller any inconvenience in manipulation would be a serious drawback.



FIGS. 1, 2 AND 3.—REGULATING AND REVERSING CONTROLLERS.

To meet the peculiar requirements of such service, controllers possessing the desired features have been designed. One style of such a device, the commutator type, as made by Westinghouse Electric and Manufacturing Company for use with direct-current series, shunt and compound motors, is shown in the accompanying illustrations. In form and construction it is unlike any other controller and its design enables the manufacturers to give special prominence to the qualities most desirable in an appliance of this kind.

For convenience in installation, it is made in two forms. In one type the controlling mechanism is mounted on the side of the frame containing the resistance, and in another it is mounted above the resistance as shown. The space available for installing controllers for motors used with cranes and other machinery is usually greatly restricted, and this provision for adapting the device to the place in which it is to be used is of corresponding value.

The controlling mechanism is mounted upon a circular slab or base of insulating material, which provides high insulation between adjacent contacts and between the contacts and ground. Throughout the entire controller, ample provision for insulation is made.

Both the contact and finger tips can be easily removed and renewed without disturbing the connections. The contacts are arranged in parallel rows along the periphery of the disc, the relative position of the contacts and the finger tips being the same as that of the brushes and commutator in a generator or motor—a form which has been found more desirable than any other for this particular service. The same contacts are used for application of the current in either direction, thus lessening the number required, while an effective magnetic blow-out makes it impossible to maintain an arc and prevents burning of the contacts.

Each controller has four brush holders mounted upon a rocker arm to which the handle is attached directly, working without gears or pinions. A single movement to right or left applies or reverses the current, and the distance the handle is moved determines the motor speed by varying the amount of resistance in series with the motor armature. There are sixteen steps in each direction and a very close regulation of the speed is thus obtained.

When the controller is placed in the rear of a crane cage, it is operated by a crank and lever directly attached to the spider which carries the brushes. The second type above mentioned, with the controller mounted above the resistance, is very generally employed for this purpose.

The resistance used with controllers of large capacity is of the grid type, a form the desirability and simplicity of which are universally conceded. For small capacities with large ohmic resistance an improved cell resistance is employed with ventilating spaces between the cells, which are separated by non-combustible insulating spreading blocks. This form provides excellent ventilation, insulation and durability. The resistance is varied for the different capacities and uses of the motor which the controller governs, a different resistance being used for crane controllers where a closer regulation is required than is provided for roll tables and soaking pits, where sudden and repeated starting and reversing is the prime requisite.

The chief characteristics of this type of controller are its simplicity, strength, durability, flexibility of application, and ease of manipulation. Any mechanic can care for it, and keep it in order, the cleaning, oiling and renewal of contacts when necessary, being all that is required. All parts are exposed to view, and connections are easily made.

Controllers of the commutator type are made regularly in capacities of from 3 to 75 hp, but are furnished especially of any capacity desired. For less than 10 hp, the Westinghouse Company makes a face plate type of controller which contains many of the main features of the device described. It is small and compact; has contacts and finger tips which are easily renewed without disturbing the connections; has a powerful magnetic blow-out, and in principle and manipulation is the same as the commutator type. The resistance used is especially designed for the purpose and is particularly effective and durable, withstanding an extraordinary amount of heat without impairing its efficiency.

The three types illustrated afford a choice of a regulating and reversing controller suitable for any service within the range of capacity named.

Flush Receptacle and Plug.

A flush receptacle and plug is ordinarily used as a means of connection between an electric circuit and some portable device requiring current. It is obvious that the simpler the means of making this connection between the plug, which is attached to the device by a flexible conductor, and receptacle, which is stationary and fastened in the wall—the better the result. In the usual receptacle and plug, one hand is required to open the face plate and the other to insert the

FIG. 1.—FACE PLATE.

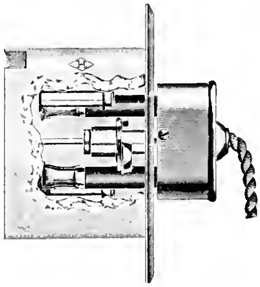


FIG. 3.—PLUG AND RECEPTACLE COMPLETE.

plug. In the "Diamond H" receptacle and plug, the shutter for the opening in the face plate is automatically operated by the plug itself —one hand, only, being required.

These receptacles are made in gangs of any number, or are put in gangs with the "Diamond H" push button or rotary flush switches, and will fit the usual wall appliances designed for these

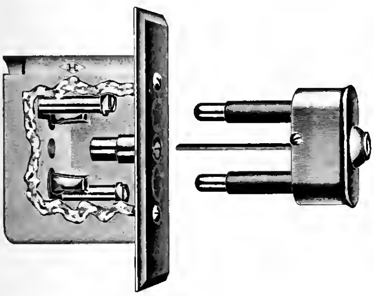

FIG. 2.—RECEPTACLE AND PLUG.

switches. Fig. 1 is a cut of the face plate, plug removed; Fig. 2 shows the plug in a position for entering the face plate; Fig. 3 shows the plug and receptacle complete.

The device is manufactured by The Hart Manufacturing Company, Hartford, Conn., manufacturers of switches bearing the same designation.

Variable Speed Too Drive Motors.

In order to meet the demand for variable speed in motors for tool driving, the Commercial Electric Company of Indianapolis, Ind., have brought out a line of Commercial variable speed motors specially designed to meet the problems connected with the subject. In these machines herewith illustrated (Fig. 1), the variation of speed is accomplished by means of a double commutator armature, having two different windings; but each winding is of the same size conductor or of the same ampere capacity. A range in speed is secured of four to one, in twelve uniformly graded steps without overlapping. A speed controller is furnished for making the necessary combination of these armature windings and for varying the field strength to secure the intermediate steps between the armature combinations. These controllers are simple and compact and the changes from minimum to maximum speed are easily and quickly effected. The controllers are made reversible. Included in the controller is the rotary starting and reversing switch, by means of which the motor is started, stopped and reversed, while the speed control is set at any desired point. The speed controller and starting switch are combined into one piece of apparatus and enclosed in a neat compact case which can be placed at any desired point on a driven tool, or which can be mounted on a stand con-

FIG. 1.—VARIABLE-SPEED MOTOR.

FIG. 2.—CONTROLLER.

veniently located by the side of the tool. This controller may contain a main switch or not, as may be desired. Fig. 2 shows a universal interlocking controller and stand. Fig. 3 illustrates the motor equipment in connection with a standard machine lathe. The litera-

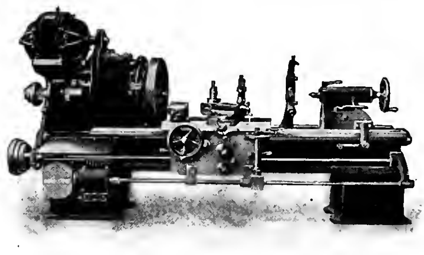

FIG. 3.—MOTOR-DRIVEN LATHE.

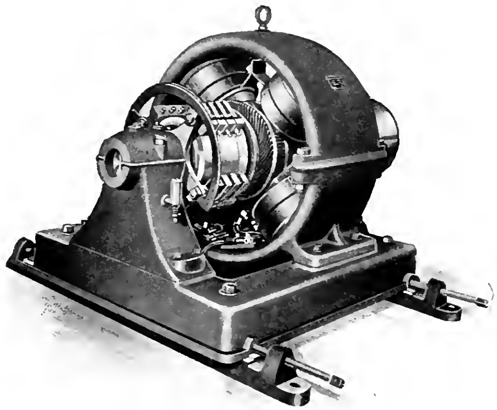
ture of the company gives further data, including some interesting curves of performance. The motors range from 2 up to 20 hp, weighing 500 pounds in the smaller of these two sizes, and 2,475 pounds in the larger.

"Ideal" Multipolar Generators.

The cut herewith shows the new line of generators being manufactured by The Ideal Electric and Manufacturing Company, Mansfield, Ohio, and is known as its "Type D," ranging in capacity from 25 to 150 kw. They are four pole up to and including 40 kw, slow speed; the larger machines being of six pole design. The magnet frame is of soft cast iron divided horizontally in all sizes and with forged steel magnet poles of circular cross section cast welded into the frame so as to insure an absolutely perfect magnetic joint. These poles are provided with cast-iron shoes which protect and support the field windings and embody the special features of this construction in reducing the density of the magnetic flux where it enters the armature, and permitting the use of a comparatively large air gap.

The armature is of the iron-clad type having a laminated core of the best quality of sheet steel of very thin gauge. Ventilating ducts are provided at right angles with the shaft and transversely through the core, insuring perfect ventilation. In the smaller sizes the core discs are mounted directly on the shaft and securely keyed thereto; while the larger sizes are provided with armature spiders so devised that the armatures can be arranged for mounting directly on the extended crank shaft of the engine for direct-connected service. Ribbed flanges are mounted on the outer edges of the core discs which ventilate the outer surface of the armature core and the windings at the bend of the coil. The windings consist of form-wound coils made of flat copper strip thoroughly insulated with horn fibre linen tape, dipped in the best quality of insulating varnish and thoroughly baked. Surface bands are used to retain the coils in the slots.

The commutator segments are well proportioned, being of sufficient length and depth to allow ample margin for wear. The flanges are of cast iron, insulated from the segments with solid V rings. The mica segments are of the best grade of pure, soft mica and the mechanical construction of the commutator is very rigid. Copper-coated composition carbon-graphite brushes are also used, clamped directly on the face of the holders. The holders are of heavy brass construction amply large to carry all current required without heating. The holders are of such a type that the brushes operate without vibration and the machines run cool and sparkless. The brush holder stems to which the holders are fastened are insulated from the quadrant and firmly secured in place to prevent



MULTIPOLAR GENERATOR.

them from working loose. The brush surface never exceeds 30 amperes per square inch of carbon contact.

The generators are designed to operate at their full rated capacities without a rise in temperature to exceed 30° above the surrounding air in either the armature or field winding, and 35° C. rise in the commutator. They are built to operate at an overload of 25 per cent. for two hours, and to withstand an overload of 50 per cent. for two to three minutes without injurious heating or sparking. The machines are thoroughly tested before leaving the works and guaranteed against defective workmanship or material.

Series Enclosed Arc Lamps.

A series enclosed arc lamp for use on 9.6 ampere circuits, which has now been in successful use for over six years, is now being made in quantities for the general market by Mr. W. F. Warner, of Muncie, Ind., its inventor and designer. During the past nine months, the lamp has been introduced in a number of cities, and has found favor as a lamp made for electric light men by one of themselves. Mr. Warner has had a number of years of experience in the manufacture of electrical instruments, and for over twelve years has had active control of electric light plants. Throughout this period he has been impressed with the need for such a lamp as he has worked out and introduced. The lamp is a very radical departure from the ordinary arc lamp construction. It is of the shunt feed type, and is purely electrical in its operation. The shunt coil does not control the feed of the carbon in the usual mechanical way, but does it electrically. Mr. Warner has therefore been able to simplify the interior of the arc lamp very much, doing away with springs, levers, cut-outs, pinions, and other familiar features.

While the lamp was designed especially for 9.6 amperes, and gives satisfactory service, operating on 50 volts at the arc, it will work equally as well, or perhaps better, on circuits of lower amperage. It is furnished for multiple work as well as series. The lamps are enclosed within a sheet copper hood, and the finish is natural copper for the hood, and aluminum finish for the top and bottom castings.

It might be well here to mention three of the features which have made the "Warner" enclosed arc lamp a success on circuits of such high amperage. In the first place he uses a globe which is considerably larger than the ones used on ordinary enclosed arc lamps, and instead of using an iron gas cap, he has made the gas cap entirely of an insulating material in one piece, which is an insulator to both heat and electricity. This cap with its globe is at a reasonable distance from the bottom of the lamp body, permitting the air to circulate around and about the globe, and the

SERIES ENCLOSED ARC LAMP.

gas cap so as to dissipate the heat without allowing it to enter the lamp body, and thereby raise the temperature of the mechanism.

The cut shows an outer globe which has some radical features. Most of the objections made to enclosed arc lamps lie in the extra time required to trim, and the many broken outer globes on account of having to remove these each time the lamp is trimmed. The Warner globe has a large opening at the bottom to allow the inner globe to be removed and the lamp trimmed without having to take the outer globe off. This saves considerable time in trimming a lamp, and many broken globes, aids very much in keeping the inner globe cool, and has thereby increased the life of the inner globe itself.

Electric Signs and Letters.

The increasing requirements in regard to safety, durability and good appearance of electric signs and letters have caused the in-

FIG. 1.—ELECTRIC SIGN.

troduction of steel in their construction. The Haller Machine Company, of Chicago, has given much thought to improving the construction of electric signs and letters, and has put on the market such

FIG. 2.—ELECTRIC SIGN.

goods. These signs are constructed of galvanized sheet steel, and although they are quite rigid and strong they are surprisingly light. The signs are decorated with embossed metal ornaments and scroll work, finished in gold leaf and colors, and are, therefore, very attractive also as day signs. The sign letters have a glossy white enameled face, reflecting the light brilliantly, while the sides are usually bright red, and the background smalted blue or black. All parts, the letters, ornaments and background, are in one piece, and none can come loose. The metal has further the advantage that it does not shrink, warp or crack, and is incombustible, waterproof and weather-proof. The lamp sockets used have removable shells. The letters are made either in the old raised or box shape, in a novel depressed or grooved style. The latter need fewer lamps and less current, as the light from the lamp is concentrated in the grooves of the letters that show up in distinct outline and can be read at any angle without blurring.

Besides different kinds of flashers, automatic switches, etc., the above company has also put on the market Goltz's automatic dimmers, by which the lights are quickly brought from darkness to full brightness, in which they stay a while, and then turn quickly to darkness, staying dark for a while, etc. The duration of darkness

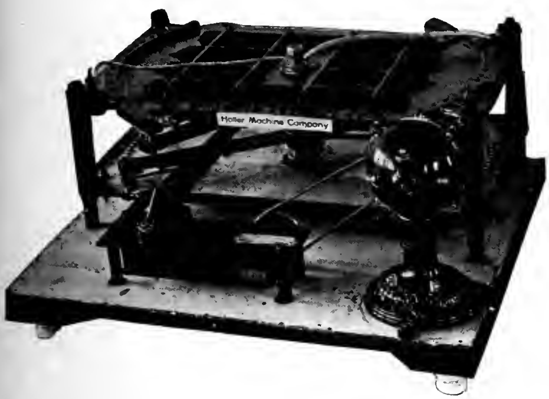


FIG. 3.—AUTOMATIC SIGN DIMMER.

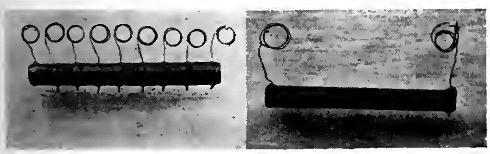
and brightness can be regulated and thereby any desired saving of current made, say from one-half to two-thirds. Double dimmers operate as described above, on two parts of a sign in rotation.

Besides full background signs, the Haller Machine Company manufactures wire screen signs, roof signs and single electric letters from seven inches up to twenty-five feet in height. The small cuts herewith, Figs. 1, 2 and 3 show a raised letter sign, a grooved letter sign and a large automatic double sign dimmer.

New Resistance Unit.

Mr. H. Ward Leonard, president of the Ward Leonard Electric Company, has designed and perfected a resistance unit to meet the most advanced ideas regarding permanent high resistance. It is a porcelain tube, the thickness of a lead pencil, and only 2 in. long, with 5,000 ohms of resistance, but with only one layer of wire. The enamel covers all the resistance wire and the connection between



HIGH RESISTANCE UNITS.

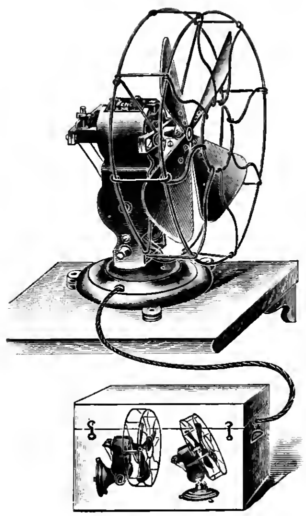
the small resistance wire and the larger terminal lead wire. The wire and joint are, therefore, hermetically sealed from the atmosphere and its corrosive action. Eleven thousand ohms can be put upon a tube 4 in. long by 7/16 in. diameter.

The cut shows a high-resistance unit tapped, giving eight equal steps of resistance. These units are especially applicable for use in constructing small rheostats, telephone resistance, etc.

Battery Fan Motor.

Many of the early battery fan motors were grotesquely inefficient, but in this line as in others, good engineering design has been brought to bear. The fan motor shown herewith, built by the Knapp Electric Novelty Company, of New York, may be cited as an illustration of improvement in this field.

This efficient, attractive and low-priced fan, taking current from portable batteries and easily moved as occasion requires, is designed for use where the street current is not available. The field is formed from steel punchings and the armature is drum-type with six teeth.



BATTERY FAN MOTOR.

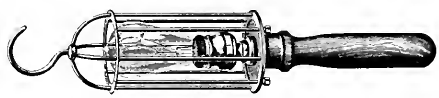
The brushes are readily adjusted while the motor is running, and oil cups with automatic feed keep the motor at the point of proper lubrication.

The fan is mounted on an iron base fitted with starting switch and rubber feet. It throws a good breeze directly forward or can be tilted to an angle either up or down or made into a wall bracket fan by adjusting the wing nuts at the lower sides of the field.

Good dry cells, connected four in each series of five multiples (twenty cells total) will draw so small a fraction of an ampere from each cell as to hold the voltage and enable the battery to stand up to the work. Used only four hours per day, about 300 hours can be obtained. If worked continuously, not allowing the battery to recuperate, the length of life is, of course, greatly reduced. Where constant work is necessary, as in a sick room, etc., it is more economical to have extra sets of battery. Two storage cells, or two or three acid cells, according to the amount of current back of them, will also give good results.

Portable Lamp Guard.

A new portable lamp guard is the latest addition to the "Crescent" line manufactured by the Crescent Company, of Chicago. After



LAMP GUARD.

many experiments the concern is able to furnish a portable lamp guard designed for all requirements. Its construction is such that, while it is strong enough to withstand the hard usage of an engine or boiler room, it is sufficiently ornamental for offices. As will be seen it is provided at one end with a hook for suspension and at the other end with a handle, so that it can be carried around easily and safely.

NEWS OF THE WEEK.

Financial Intelligence.

THE WEEK IN WALL STREET.—Values in the stock market at the close of the week were irregular at concessions following a recovery from a general decline earlier in the week. Bearish influences arising from the disturbed financial situation abroad and railroad cutting at home accounted for the decline. The public took little interest in the market, which was narrow in consequence. The heaviness of the trunk line shares, particularly Pennsylvania, was noted, and New York Central later became conspicuous. Brooklyn Rapid Transit and Amalgamated Copper also became active and advanced with ease. The United States Steel shares were steady at first, but afterwards became quite weak and were depressed by renewed unfavorable reports about the earnings of the corporation. Prices on the curb for outside securities generally sagged in sympathy with the main market. The largest transactions were in rights at a lower range of prices. There were a few scattering sales of New York & New Jersey Telephone rights at 3⅝. Interurban Rapid Transit closed at 102, being a net gain of ⅛. Tractions are all lower. Brooklyn Rapid Transit closed at 39⅜, which represents a loss of 1 point. Manhattan Elevated closed at 141½, rallying from 140¾, and Metropolitan Street Railway closed at 114½, which is ½ above the lowest price and a net loss of 1½ points. In the electric list a loss of 5 points net is recorded in General Electric, which closed at 158 after having reached 163. Westinghouse closed at 158, which is a loss of 1 point compared with the closing price of the previous week. Western Union gained ½ point, closing at 87½, and Commercial Cable was off 5 points, the closing quotation being 187. Following are the closing prices of March 1:

NATIONAL CARBON.—The annual report of the National Carbon Company for the year ending January 31, 1904, already quoted in these columns, showed net earnings of $736,441 compared with $594,372 the previous year. The increase was $142,069, or about 24 per cent. Net earnings for the year just reported amounted to 7 per cent. on the $4,500,000 preferred stock, and to 7.6 per cent. on the $5,500,000 common. Nothing was paid, however, on the common, the company charging off the greater part of the surplus after preferred dividends. This has been done every year since organization, in 1899. The company has made a good record of earnings. The following table compares income accounts for the five-year period 1899-1904:

	Net earn.	Pfd. div.	Balance.	P. C. on common.	Charged off.
1904....................	$736,441	$315,000	$421,441	7.6	$280,429
1899....................	451,687	315,000	136,687	2.4	100,000
Increase................	284,754	....	136,687	5.2	180,429

This good showing is also evident in the balance sheets in the form of increased working capital. The following table compares working capital at the beginning and at the end of the five-year period:

	1904.	1899.
Current assets	$1,368,129	$890,424
Current liabilities	93,570	154,479
Net working capital..............................	$1,274,559	$735,945

The working capital shows an increase of over $500,000. Meanwhile there have been additions and improvements made to the property. The demand for carbons, quite outside the lighting field, becomes yearly more varied and the output gains in bulk and value.

COMMERCIAL CABLE COMBINATION.—It is reported that a new company will be formed which will offer its preferred stock share for share for Commercial Cable stock and issue a bonus in common stock. It was said that the new company might be formed for the purpose of combining the Commercial Cable Company and the Commercial Pacific Cable Company, which is the company incorporated in 1901 to lay and operate the cable from California to the Philippines and China. The authorized capital stock of this company is $12,000,000, and it is controlled by the Commercial Cable interests. The Commercial Cable Company increased its stock about a year ago and it was said then that a part of the $1,666,000 increase would go toward completing the Pacific cable. The cable company's stock is $15,000,000, and its bonded debt $20,000,000. This week Mr. Clarence Mackay has given out details of the scheme and has just organized an investment trust under the name of "The Mackay Companies," the design of which is to perpetuate the name of his father, the late John W. Mackay; to provide for the development of the companies which John W. Mackay founded and to safeguard, upon an even basis with Clarence H. Mackay's own, the interests of those who have invested capital in the enterprises with which his father was identified. "The Mackay Companies" has authorized for exchange for the stock noted above $30,000,000 par value of its own 4 per cent. cumulative preferred shares and a like amount of common shares, so that each stockholder in the cable company will receive for his holdings 200 per cent. in the preferred and 200 per cent. in the common shares of the new concern.

NIAGARA, LOCKPORT AND ONTARIO POWER.—Opposition is being made to the plans of the above enterprise. Julius Henry Cohen, chairman of the Legislative Committee of the Citizens' Union has given out a statement condemning the Assembly bill amending the charter of the Niagara, Lockport and Ontario Power Company. He says: "It is a measure which deserves the attention and condemnation of the press, not only in New York City, but throughout the State." The Citizens' Union recognized the danger in this bill and asked for a hearing before the Assembly Committee on General Laws. The delegation which went to Albany and opposed the bill came away with the general assurance that it would be materially amended. But the bill is, in its amended form, a dangerous measure. Here is a company which was given a franchise ten years ago. It has not yet spent one cent on actual construction. It is now proposed to extend its time, to give it the right to deface Niagara, without any compensation to the State, and to give it extraordinary franchise rights in every city and town of the State. The pretended probition in the amendment does not prohibit it for, by combining with a local company in any city or town, it will have a perfect franchise, even in New York City, to rip up the streets, lay conduits, erect poles, and exercise any other powers enumerated above."

NORDEN-BITTNER ELECTRIC COMPANY.—A petition in bankruptcy has been filed against the Norden-Bittner Electric Company, manufacturer of electric supplies, of New York City, by the following creditors: Munder Electric Company, of Springfield, Mass., $816; Joseph George, $68, and O. E. Nantel, $16. It is alleged that the company is insolvent, and in January and February transferred cash to certain creditors to prefer them. John Bittner was president and treasurer, and M. Norden secretary and manager. It was incorporated on August 16, 1901, with a capital stock of $100,000. Judge Holt of the United States District Court appointed Job E. Hedges receiver of the assets on the application of Stern, Singer & Barr, attorneys for the petitioning creditors, who stated that the assets are about $8,000, of which $5,000 are collectable accounts and the balance merchandise. The cause of the bankruptcy petition was the withdrawal of Mr. Bittner, as he declined to advance any more money to the corporation.

ST. LOUIS LIGHTING.—The stockholders of the Laclede Gas Light Company of St. Louis, which is controlled by the North American Company, will hold a special meeting on April 18 to vote upon a proposition to increase the common stock from $8,500,000 to $17,500,000, making the total capital, including preferred stock, $20,000,000. A vote will be taken at the same time on increasing the bonded indebtedness from $10,000,000 to $20,000,000. In a circular to the stockholders, President C. W. Wetmore of the North American Company says that $5,000,000 cash will be needed before February 1, 1905, to meet expenditures for improvements and extensions incidental, largely, to the contracts of the company for the St. Louis Exposition period. The fresh capital will also provide for the development of the business of the company for a series of years. It was said that a local banking house was prepared to take the entire $10,000,000 issue of Laclede bonds and that there would be no syndicate to handle them.

NEW YORK AND NEW JERSEY BELL TELEPHONE.—The New York and New Jersey Telephone Company has issued its full report for the year ended December 31, 1903. Below are some of the figures:

	1903.	1902.	1901.	1900.
Gross	$4,741,344	$3,962,597	$3,376,433	$2,827,481
Expenses	3,269,996	2,823,458	2,294,633	2,018,603
Net	$1,471,348	$1,139,139	$1,081,800	$808,878
Charges and taxes	181,214	166,350	174,104	174,731
Surplus	$1,290,134	$972,789	$907,696	$634,147
Dividends	852,216	707,627	616,286	490,650
Surplus	$437,918	$265,162	$291,410	$143,497

Earnings and expenses in detail follow:

Gross earnings:				
Exchange service	$2,262,289	$1,903,707	$1,633,319	$1,372,916
Pay stations	596,031	490,294	428,996	356,560
Tolls	1,656,943	1,365,854	1,162,279	965,341
Leased lines and instruments	23,730	....	....	....
Real estate	132,803	113,415	107,415	83,939
Other sources	69,547	89,327	44,424	48,725
Total	$4,741,344	$3,962,547	$3,376,433	$2,827,481
Expenses:				
General	$761,541	$646,240	$536,665	$504,613
Operating	761,331	594,730	522,071	460,840
Reconstruction and maintenance	1,446,050	1,330,172	997,828	847,649
Instrument rental	219,950	181,616	176,855	147,417
Real estate	81,124	70,699	61,214	58,085
Total	$3,269,996	$2,823,457	$2,294,633	$2,018,603

BALTIMORE UNITED RAILWAYS.—The United Railway & Electric Company of Baltimore reports as follows for the year ended December 31, 1903:

	1903.	1902.	Changes.
Gross	$5,480,629	$5,041,275	Inc. $439,354
Expenses	2,554,241	2,252,133	Inc. 302,108
Net	$2,926,388	$2,789,142	Inc. $137,246
Other income	90,374	53,405	Inc. 36,969
Total income	$3,016,762	$2,842,547	Inc. $174,215
Changes	2,708,030	2,637,115	Inc. 70,915
Sulplus	$308,732	$205,432	Inc. $103,300

CANADIAN BELL TELEPHONE.—The Bell Telephone Company of Canada makes a satisfactory annual report as follows for the year ended December 31, 1903:

	1903.	1902.	Changes.
Gross	$2,522,275	$2,085,134	Inc. $437,141
Expenses	1,940,123	1,580,852	Inc. 359,271
Net	$582,152	$504,282	Inc. $77,870
Dividends	467,510	....	....
Surplus	$114,642	....	....

The capital stock of the company is $6,000,000, of which the American Telephone and Telegraph Company owns $2,314,700.

UNION SWITCH & SIGNAL COMPANY.—The following is a summary of the annual report of the Union Switch & Signal Company for the year ending December 31, 1903, as compared with previous years:

	1903.	1902.	1901.	1900.
Gross receipts	$2,132,835	$1,774,005	$1,605,649	$1,690,319
Interest and other disbursements	1,803,513	1,420,322	1,308,143	1,300,406
Net	$329,322	$353,683	$297,506	$389,913
Preferred dividends	130,867	79,726	79,726	79,726
Surplus	$198,455	$273,957	$217,780	$310,187

DIVIDENDS.—West Jersey and Seashore Railroad directors have declared the regular semi-annual dividend of 2½ per cent., payable March 15. The South Side Elevated, Chicago, has declared the regular quarterly dividend of 1 per cent., payable March 31.

Commercial Intelligence.

THE WEEK IN TRADE.—Winter's icy grip on trade seems to be relaxing, according to reports from the various sections, and although severe weather conditions still exist in some, spring trade is asserting itself. Distributive trade in the South has been good and generally in excess of a year ago, and the milder weather has brought out more country buyers. In the East spring trade is growing, but retail business is still restricted by the continued cold weather. Manufacturing plants are gradually restoring idle machinery, and there is more disposition to anticipate future requirements. In the building trades there is every indication of activity with the advent of spring. The cold weather still hampers outdoor operations, but several very large transactions in lumber are reported from the West and Northwest. Baltimore concerns are resuming in temporary quarters, stocks of goods being accumulated with great rapidity, but no permits have been issued for rebuilding the burned district, as plans are in preparation for realignment of the streets. Foreign commerce at New York for the last week shows a loss of $2,489,799 in exports and a decrease of $2,549,672 in imports as compared with the same week last year. The strength of the wheat market, and of the coarser grains, which is looked for to increase, and of provisions generally, are the leading features of the price situation. War talk is still an influence tending to strengthen food products, but to depress raw cotton. Collections are still unsatisfactory at most Northern markets. Money is easy and deposits show increases at leading centers. Railway earnings are not as encouraging as in the past, owing partly to the congestion growing out of blockaded shipments, but partly to cutting of grain freight rates, which, despite the small movement at present, affects the situation appreciably. Iron and steel are still irregular, but the tendency, as a whole, has been in the direction of improvement, owing to the enlarged demand reported for finished products, notably bars, wire and wire goods, steel pipe, and light and heavy hardware. The liabilities of the commercial failures thus far reported for February aggregated $10,796,166, of which $2,732,453 were in manufacturing, $4,290,235 in trading, and $3,773,453 in other commercial lines. *Bradstreet's* summary of business failures for the week ending February 25 shows that there were 200, against 23 the week previous, and 185 the corresponding week last year. Copper remains unchanged, dullness still being the prevalent condition in the market. Quotations are, for Lake, 12½ to 12¾.; electrolytic and casting stock, 12⅜ to 12⅝c. The exports so far in February show a marked falling off, the shipments amounting to but 8,800 tons.

THE ELECTRIC STORAGE BATTERY COMPANY, of Philadelphia, has recently closed a number of contracts for the installation of batteries of "Chloride" accumulators. Among them may be noted two batteries of the North Shore Railroad Company, one to be located at San Anselmo, Cal., having a capacity of 846 kw, the other located at Sausalito, Cal., having a capacity of 975 kw. Both these batteries to be used for line regulation. The Bay City Traction and Electric Company, Bay City, Mich., have contracted for a battery having a capacity of 288 kw, to regulate the fluctuations of the generator lead. The Northwestern Fuel Company, Superior, Wis., have contracted for a battery having a capacity of 677 kw, which is to be used entirely for the regulation of a motor load. The Bartlett Illuminating Company will install for the use of the Saginaw Traction Company a battery having a capacity of 200 kw, to be used in regulating the fluctuations on the latter company's railway circuit.

NEW POWER STATION FOR NEW ORLEANS.—The construction of a new power station is contemplated by the New Orleans (La.) Railway Company, for which concern Sanderson & Porter, 52 William Street, New York, are the consulting engineers. The proposed new plant will have an initial capacity of 7,000 hp, while eventually it will be capable of developing 20,000 hp. Alternating-current equipment will be installed.

MEXICAN WATER POWER PROJECT.—Mexican advices state that L. B. Cabellero, of Mexico City, has secured the necessary concession from the Secretaria de Fomento by which he is permitted to utilize 3,000 liters of water per second from the Realito River of Tubares, in the District of Andres del Rio, State of Chihuahua. The current so generated will be used for lighting and general power purposes in that vicinity.

CORTLAND (N. Y.) PLANT TO BE REMODELED.—The power station of the Cortland County Traction Company, Cortland, N. Y., is to be remodeled. The existing equipment consists of Watertown engines and belt-driven General Electric railway generators. Two new 200-kw generators will be installed. Jeremiah J. Kennedy, Exchange Court, New York, is consulting engineer.

EQUIPMENT FOR GOUBERT PLANT.—The Goubert Manufacturing Company, 85 Liberty Street, New York, will award contracts shortly for considerable electrical equipment to be installed at its new plant, Bayonne, N. J., where, in addition to the feed-water heaters, steam separators and other specialties of the company, large castings, such as engine cylinders and marine engine work, will be turned out. There will be four foundry buildings, one being 70 ft. x 310 ft. and three, each measuring 60 ft. x 310 ft. The larger building will be equipped with a 40-ton, also a 25-ton electric traveling crane, and each of the other buildings will have a 25-ton equipment. The machine shop will be 90 ft. x 400 ft. The equipment will be operated electrically, the larger tools being driven by individual motors, while the smaller ones will be worked by means of line shafting operated by motors. The power plant will be of 300-hp capacity. The engine will be direct-connected to the generator and of compound non-condensing type. The boilers are to be water tube equipped with superheaters. There will also be a blacksmith shop and plate shop, and various other buildings for storage, pattern-making and similar purposes. Industrial railways will be installed in the plant so as to connect the buildings and supplement the crane and railroad service, as a spur of the Central Railroad of New Jersey will be run to the works, which are located on the water front.

ELECTRIFICATION OF SOUTH AUSTRALIAN STEAM LINES.—Regarding the proposed electrification of the suburban railways in South Australia, advices state that for working the Port Adelaide and Glenelg lines, three alternative schemes are outlined in a report recently prepared on the subject by the Railways Commissioner and leading officers of the department. Two of the schemes are on the high-tension system with one power station, and one on the low-tension system with two power stations. The third scheme has been recommended for acceptance in view of its being the least expensive both as regards installation and as to maintenance. T. Roberts, the chief mechanical engineer of the South Australian Railways, estimated the capital cost at about $1,500,000 and the annual cost at about $170,000, provision being made for 48 cars and as many trailers. The Railways Commissioner, Alan G. Pendleton, thinks the work should be carried out on this scheme. As difficulties are anticipated in operating cars successfully in and out of the Adelaide station, an estimate has been made of bringing the cars into North Terrace by a deviation from the Port line. Such a deviation is calculated to incur an expenditure of $150,000—$125,000 for the track and $25,000 for electrification.

AMERICAN SIGNALING FOR YERKES.—The Underground Electric Railways Company, Limited, of London (usually referred to as the Yerkes' Syndicate), which is constructing an extensive underground and surface electric traction system in and around the British metropolis, has decided to utilize an American system of signaling on the 15 miles of double track of the Metropolitan District Railway. The contract has been awarded to the Westinghouse Brake Company, Limited, of Kings Cross, London, N., which concern has the British rights to manufacture the specialties of the Union Switch and Signal Company, of Swissvale, Pa. The signals will be operated automatically on the Westinghouse electro-pneumatic system and are to be about 300 in number. The service in the tunnels will be arranged for trains running at intervals of 1¼ minutes. A new form of combined signal motor and arm will be employed. This system has been in service for several months past on the Ealing-Harrow experimental section of the Metropolitan District Railway. This is the first instance of a British electric railway to be automatically signaled by means of track circuits.

THE ST. LOUIS SMELTING AND REFINING COMPANY of St. Louis, Mo., is erecting a new smelter at Collinsville, Ill. After considering the matter, on the advice of its consulting engineer, Mr. Henry Floy, of New York City, it has decided to use electric power throughout and has placed orders with the General Electric Company for three-phase motors, varying in size from 75 hp down, and a 240-volt alternator, to be direct connected to a Rice & Sargent tandem, compound engine, operating at 150 r.p.m. The Babcock & Wilcox Co. has been awarded the contract for boilers; the Deane Steam Pump Company has received the order for pumps, and the Buffalo Forge Company, the order for blowers. It is expected the plant will be in operation by July 1, 1904.

BELL TELEPHONE OUTPUT.—The American Telephone and Telegraph Company instrument statement for the month ended January 30, is as follows:

	1904.	1903.	1902.
Gross output	90,644	129,837	87,412
Returned	36,854	43,286	34,796
Net output	53,790	86,551	52,616
Total outstanding	3,833,307	3,236,871	2,578,626

While there is a large total gain over last year, there is an apparent decline in net for the month of nearly 33,000 instruments, the net being barely in excess of the same month in 1902.

THE RIO TAMASOPO SUGAR COMPANY, of which Col. Russell B. Harrison, of Indianapolis, is president, will shortly be in the market for considerable electrical equipment, etc., to be installed on its plantation known as the Agua Buena Hacienda, located about 130 miles west of Tampico, Mexico. A horse tramway is now used for the purpose of hauling the sugarcane from the fields to the mill and conveying the sugar thence to the Mexican Central Railroad at Tamasopo, a distance of about five miles. This line will be converted into an electric traction system. A lighting plant will also be installed for lighting the sugar factory and other buildings on the plantation. The sugar mills are to be operated by water power.

DODGE & DAY, modernizing and contracting engineers, Nicetown, Philadelphia, Pa., are installing in the power house of the Link-Belt Engineering Company, Philadelphia, Pa., a 340-hp Buckeye vertical cross-compound engine, direct-connected to two General Electric 100-kw direct-current, compound-wound generators. The boiler plant at the same establishment is also receiving attention, and while it may not be found necessary to increase the capacity, it is probable under-feed stokers will be introduced. The Taylor system of management is well underway at the Link-Belt Works, and the results attained have been most gratifying.

TRUMBULL SPECIALTIES FOR MEXICO.—Adolphe A. Chaillet, formerly technical director of the Shelby, O., Lamp Company, is now located in Mexico City, where he is primarily interested in a project to manufacture incandescent lamps for that market. He also represents the Mexican interests of a number of United States manufacturers of electrical equipment supplies, etc., and has placed a substantial contract for fusible cleat rosettes, plug cut-outs, switches and other specialties, with the Trumbull Electric Manufacturing Company, New York, offices 136 Liberty Street.

THE FRENCH THOMSON-HOUSTON COMPANY has received a new order from the Paris Metropolitan Railway for 100 complete train control equipments similar to those in use on the Central London Railway, Great Northern and City Railway, the Northeastern Railway and the Metropolitan and District Railway. This order is all for new equipment in addition to that heretofore in use or on order, and is said to be the only additional equipment ordered by the Paris Metropolitan.

ELECTRIC SUPPLY CO., of 298 Second Street, Memphis, Tenn., is having a new store and warehouse built for it in that city, which it expects will be ready for occupancy about May 1. This warehouse will enable it to increase materially the supply stock carried. It proposes also to do a general jobbing business throughout the South. Mr. C. H. Harvey is president, and Mr. W. M. Deming is secretary and treasurer.

MAGNET WIRE ORDERS.—The Magnet Wire Company, 80 William street, New York, report receipt of a quantity of inquiries for feeder cable and trolley wires from the South and Middle West, as well as in this section. A substantial contract for feeder cable has just been secured from the Rochester (N. Y.) Railway Company, and the Pittsburg (Pa.) Coal Company has also sent in a good-sized order for trolley wire, etc.

THE POWER AND MINING MACHINERY COMPANY, of Cudahy, Wis., is enlarging a plant, and in connection therewith desires a number of electric motors, in capacity of 5 to 50 hp, constant speed, wound for 220 volts. The main office of this company is 52 William Street, New York, where the bids and correspondence in connection with this matter will be received.

EQUIPMENT FOR NEW STURTEVANT HOTEL.—The new Sturtevant Hotel under construction at Twenty-ninth street and Broadway, New York, which is being built by the George A. Fuller Company, is to be installed with two 225-hp Harrisburg engines, each directed connected to 150-kw C. & C. generators, and two 120-hp direct-connected to 75-kw C. & C. generators.

HOBART ELECTRIC MFG. CO., of Troy, Ohio, is contemplating the erection of a brick addition to its factory, 220 by 50 feet. It will use its own power plant, but will need additional machinery and tools. It had not let any contracts at the time of writing, but is expecting to have some of them closed immediately.

LIGHTING.—Orders are expected within the next few days for lighting equipment to be installed in the New York plant of the Federal Sugar Refining Company. There will be about 3,000 incandescent lamps. Edward R. Knowles, 136 Liberty Street, is acting as the consulting engineer in the matter.

TRACTION FOR ADELAIDE, AUSTRALIA.—Private advices from Adelaide state that it is confidently expected that the existing horse tramways in that South Australian city will shortly be converted into electric traction. The present lines are about 30 miles long.

UTILIZING HAT RAPIDS, WIS.—A company to be known as the Rhinelander Power Company has been organized with the following officers: A. W. Shelton, president; E. A. Forbes, vice-president; Charles Chafee, treasurer, and C. A. Wixson, secretary. The power company is capitalized at $85,000, $40,000 of which has been subscribed by the above named, some of whom are connected with the Rhinelander Electric Light Company, and who will begin at once the development of the excellent water power a few miles below Rhinelander, Wis., known as Hat Rapids. Their first move will be to have a new and accurate survey made of the power, and follow it up with the construction of a dam, giving a 20-ft. head, and which it is estimated will be capable of developing up to 1,500 hp. The concern will be a lighting and power company, and there is not the slightest doubt that there will be a demand for all the power developed. The Rhinelander Manufacturing Company, the Wisconsin Veneer Company, the Rhinelander Paper Company, the Rhinelander Iron Company, the city pumping station, etc., will be in the market for electric power as soon as the development is completed and the current turned on. An estimate of the time required for the completion of the work is given as six months.

OTIS ELEVATORS FOR YERKES' LONDON SYSTEM.—The Otis Elevator Company, Limited, of London, has been alloted the contract for the "lifts" for the whole of the Yerkes' system of tube railways in the British metropolis. The elevators will be operated by power transmitted from the central station at Chelsea. There will be 170 elevators in all, capable of carrying an average of 65 passengers at a time, or nearly 100,000 people all told. The speed will be 200 feet per minute. The underground stations will be fitted in most cases with four and in some cases six elevators each. The average rise will be 60 feet. The machinery will be of the Otis type and special safety appliances and non-flammable material are to be employed throughout the mechanism and its accesories. The shafts will vary from 40 feet to 180 feet in depth; the majority of the shafts will be 23 feet in diameter and some will be 30 feet in diameter. It is expected that the bulk of the equipment will be manufactured on the other side. The contract, which is the most valuable ever let for elevators on either side of the Atlantic, will represent an expenditure of upwards of $1,750,000.

DUTY ON ARC CARBONS.—Judge Lacombe in the United States Circuit Court of Appeals in New York City last week decided the case of the United States versus R. F. Downing & Co., in favor of the importers, thereby materially reducing the duty to be exacted on carbons for electric arc lights. These carbons, in the condition in which they are used, are 12 inches long, and they are specifically provided for in the tariff law at 90 cents a hundred. Some years ago the importers tried bringing them in in longer lengths, from 12½ to 20 inches, and the claim was made that they were entitled to classification as articles manufactured of carbon at 35 per cent. This claim was overruled by General Appraiser Fischer on November 7, 1901, and Judge Henderson M. Somerville wrote a dissenting opinion sustaining the importers' claim. This dissenting opinion is now confirmed by the Circuit Court of Appeals. The importers were represented by Comstock & Brown.

INTERNATIONAL TELEPHONE CONTRACTS.—Among the contracts recently secured in the Northwest by Mr. Henry Shafer, president of the International Telephone Manufacturing Company of Chicago, was one for a 1,000-line capacity central energy lamp signal double supervisory switchboard, distributing board, lightning arresters, complete power plant, together with a 50-number self-restoring drop country party line and tollboard for re-equipping the exchange of the Portage Telephone Company, Portage, Wis., and telephones for increasing the exchange. The Portage company will use its present generator-call telephones on the system, by cutting out the generator and cutting in an International condenser, thus changing them to centralized calling energy local talking battery instruments.

NEW STURTEVANT WORKS.—The boiler plant of the B. F. Sturtevant Company's new works at Hyde Park, Mass., is now in full operation. This plant comprises three 250-hp Stirling boilers equipped with Jones under-feed stokers, air for which is furnished by a 6 ft. x 28 in. Sturtevant steam fan operating at 2½ oz. pressure, a 9 x 4½ ft. Sturtevant induced draft steam fan, and an economizer (to be installed later) of their own make. The maximum steam pressure carried will be 150 pounds. Fire was started under these boilers on December 23. This company has in process of construction a 400-hp vertical compound engine with direct-connected 250-kw generating set, which will be the first of several units to be installed in the engine room.

THE NERNST LAMP COMPANY has appointed Mr. G. E. Bennett to act as district sales manager of its Buffalo district office, recently established at 17 West Mohawk Street. These quarters will include an office, show room, exhibition room and stock room, with a complete stock of lamps and supplies to meet the requirements of the trade in this territory. The company has recently closed contracts for the installation of 165 Nernst lamps in the Washington National Bank Building, and 75 lamps for the Pittsburg Supply Company, at Pittsburg, Pa. It has also succeeded in securing the adoption of Nernst lamps by the municipal electric light plant of Silverton, Colo., in competition with enclosed arc lamps.

MEXICAN HYDRAULIC PROJECT.—A hydraulic plant is to be constructed on the river Alaja in the San Miguel Allende district, State of Guanajuato, Mexico. Jose de J. Garcia has been granted the necessary concession from the Mexican authorities which permits of the utilization of 1,500 liters per second. The usual franchises and obligations are embodied in the concession. A deposit of $5,000 in bonds of the Mexican 3 per cent. consolidated silver debt has been made by the concessionaire. Construction work is expected to be begun immediately and orders will be placed here very shortly for the necessary equipment. The plant will develop current for general power use.

BRIDGEPORT, CONN., MANUFACTURING PLANT.—The Eaton, Cole & Burnham Company, manufacturers of steam fixtures, etc., is to install considerable electrical equipment in its plant now being extended at Bridgeport, Conn. A Westinghouse turbine of 400-kw capacity will be put in. There will also be installed 31 Westinghouse motors varying in capacity from 5 hp to 30 hp and aggregating 350 hp. A 30-kw General Electric direct-connected exciter set has also been ordered. G. K. Hooper, Bowling Green Building, New York, is the consulting expert.

MEXICO CITY LINES EXTENDED.—The Mexico Electric Tramways Company (usually known as the Wernher-Beit system), which operates an extensive electric traction system in Mexico City and suburbs, proposes to construct a further line. The company has filed an application with the Department of Public Communications in the Mexican capital for the necessary authorization to build a line from Nino Perdido, on the south, to Los Angeles on the north side, thus forming a complete circuit.

EQUIPMENT FOR HOTEL NETHERLANDS.—Mackenzie, Quarrien & Ferguson, 114 Liberty Street, New York, have taken an order for a 150-hp Harrisburg side-crank engine for direct connection to a 100-kw Western Electric generator. The equipment will be used for lighting the Hotel Netherlands. The New York Dock Company has ordered a 75-hp Harrisburg standard simple engine for direct connection to a 50-kw General Electric generator for lighting purposes.

THE CATAWBA POWER COMPANY has secured the contract for lighting the streets of Charlotte, N. C., and advises that it is now in the market for pole line supplies for eighteen miles of transmission, high potential circuit. It is also in the market for the necessary supplies for wiring the city of Charlotte for 155 arc lamps and for private lighting and small motor work. Mr. W. S. Lee, Jr., is vice-president and general manager.

CHANGES IN CUBAN TARIFF.—Under the new Cuban tariff, which has just gone into effect, there is a 25 per cent. increase in the duty on copper wire, copper wire gauze, cables and miscellaneous articles. There is a 30 per cent. increase on incandescent lamps of all kinds, electrical insulators and electric conduits. There is a 25 per cent. increase on dynamo electric machinery, "inductors and detached parts."

AMERICAN ELECTRIC TELEPHONE ORDERS.—Among switchboard shipments recently made by the American Electric Telephone Company of Chicago are the following: Monroe, Neb., one 100-line express; Belize, British Honduras, C. A., one 200-line express; Olivet, Kan., one 100-line express; Dunlop, Ia., one 200-line express; Topeka, Kan., one 40-line express.

BALL ENGINE ORDER.—The Cleveland Arcade Company, Cleveland, O., has contracted with the Ball Engine Company, Erie, Pa., for one of its 400-hp heavy duty side crank engines, arranged for direct-connection to a Westinghouse generator. This is a new design which has been much admired by those who have seen it.

TO LIGHT CAMPECHE CITY.—The city of Campeche, capital of the State of Campeche, Mexico, is to be illuminated by electricity. The city has a population of about 22,000. The lighting equipment will be purchased in the United States. Don Luis Garcia, a prominent lawyer, is one of the principal parties interested in the project.

ELECTRIC TRACTION FOR NEW ZEALAND.—The Australasian electrical, engineering and contracting firm of Noyes Bros. has been awarded the contract for the construction and equipment of an electric traction system in Invercargill, a prosperous seaport town located in the extreme south of New Zealand.

JAPANESE LIGHTING PLANT EXTENDED.—The Yokohama (Japan) Union Electric Light Co. is to double the capacity of its plant, making 1,200 hp in all. Two 300-hp Heine boilers have been ordered. The initial boiler equipment is also of Heine build.

DIRECTORY OF ELECTRICAL ASSOCIATIONS, SOCIETIES, ETC.

(Published first issue of each month.)

AMERICAN ELECTROCHEMICAL SOCIETY. Secretary, C. J. Reed, 929 Chestnut Street, Philadelphia, Pa. General meeting, Washington, D. C., April 7, 8 and 9, 1904.

AMERICAN ELECTRO-THERAPEUTIC ASSOCIATION. Secretary, Dr. C. E. Skinner, New Haven, Conn.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS. Secretary, Ralph W. Pope, 95 Liberty Street, New York. Meetings, last Friday each month.

AMERICAN RAILWAY, MECHANICAL & ELECTRICAL ASSOCIATION. Secretary, Walter Mower, 12 Woodward Avenue, Detroit, Mich.

AMERICAN SOCIETY OF MUNICIPAL IMPROVEMENTS. Secretary, G. W. Tillson, Brooklyn, N. Y. Next meeting, St. Louis, 1904.

AMERICAN STREET RAILWAY ASSOCIATION. Secretary, T. C. Pennington, 2020 State Street, Chicago.

ASSOCIATION OF EDISON ILLUMINATING COMPANIES. Secretary, W. S. Barstow, New York City and Portland, Ore.

CANADIAN ELECTRICAL ASSOCIATION. Secretary, C. H. Mortimer, Toronto, Ont. Next meeting, Hamilton, Ont., 1904.

COLORADO ELECTRIC LIGHT, POWER & RAILWAY ASSOCIATION. Secretary, George B. Tripp, Colorado Springs, Col. Annual meeting last Wednesday in October.

CONNECTICUT STATE STREET RAILWAY ASSOCIATION. Secretary, E. W. Poole, Bridgeport, Conn. Annual meeting in November.

ENGINE BUILDERS' ASSOCIATION OF THE UNITED STATES. Secretary, F. P. Ide, Springfield, Ill. Next meeting, December, 1903.

ELECTRICAL TRADES SOCIETY (Member National Electrical Trades Association). Secretary, A. P. Eckert, 39 Cortlandt Street, New York. Board of Directors meets second Friday of each month.

ILLINOIS STATE ELECTRIC ASSOCIATION. Secretary, H. E. Chubbuck, LaSalle, Ill.

INDIANA PUBLIC UTILITIES ASSOCIATION. Secretary, A. M. Barron, Indianapolis, Ind.

INDEPENDENT TELEPHONE ASSOCIATION OF THE UNITED STATES. Secretary, Frank G. Jones.

INDEPENDENT TELEPHONE ASSOCIATION OF SOUTHERN INDIANA. Secretary, E. W. Pichardt, Huntingburg, Ind.

INTERNATIONAL ASSOCIATION OF MUNICIPAL ELECTRICIANS. Secretary, Frank P. Foster, Corning, New York.

INTERSTATE INDEPENDENT TELEPHONE ASSOCIATION. Secretary, E. M. Coleman, Louisville, Ky.

IOWA ELECTRICAL ASSOCIATION. Secretary, W. S. Porter, Eldora, Ia.

IOWA TELEPHONE ASSOCIATION. Secretary, C. C. Deering, Des Moines, Ia. Annual meeting, Des Moines, March 8, 1904.

KENTUCKY INDEPENDENT TELEPHONE ASSOCIATION. Secretary, James Maret, Mount Vernon, Ind.

MAINE STREET RAILWAY ASSOCIATION. Secretary, E. A. Newman, 471 Congress Street, Portland, Me.

MASSACHUSETTS STREET RAILWAY ASSOCIATION. Secretary, Charles S. Clark, 70 Kilby Street, Boston, Mass. Meets second Wednesday of each month, except July and August.

NATIONAL ARM, PIN & BRACKET ASSOCIATION. Secretary, J. B. Magers, Madison, Ind. Next meeting, St. Louis, July, 1904.

NATIONAL ELECTRICAL CONTRACTORS' ASSOCIATION OF THE UNITED STATES. Secretary, W. H. Morton, 44 Whitesboro Street, Utica, N. Y. Next meeting, St. Louis, Mo., September 14, 15 and 16, 1904.

NATIONAL ELECTRIC LIGHT ASSOCIATION. Secretary, Ernest H. Davis, Williamsport, Pa. Next meeting, Boston, Mass., May 24, 25 and 26, 1904.

NEW ENGLAND STREET RAILWAY CLUB. Secretary, J. H. Neal, 101 Milk Street, Boston, Mass. Meets last Thursday of each month.

NEW YORK ELECTRICAL SOCIETY. Secretary, G. H. Guy, 114 Liberty Street, New York.

NORTHWESTERN ELECTRICAL ASSOCIATION. Secretary, T. R. Mercein, 85 Michigan Street, Milwaukee, Wis.

OHIO STREET RAILWAY ASSOCIATION. Secretary, Chas. Currie, Akron, Ohio.

OHIO ELECTRIC LIGHT ASSOCIATION. Secretary, D. L. Gaskill, Greenville, Ohio.

OHIO SOCIETY OF MECHANICAL, ELECTRICAL AND STEAM ENGINEERS. Secretary, C. J. Miller, Canton, Ohio.

SOUTHWESTERN ELECTRICAL ASSOCIATION. Secretary, J. L. Ellis, Oklahoma City, Okla. Next meeting, Dallas, April or May, 1904.

SOUTHWESTERN GAS, ELECTRIC & STREET RAILWAY ASSOCIATION. Secretary, Frank E. Scovill, Austin, Texas.

STREET RAILWAY ACCOUNTANTS' ASSOCIATION OF AMERICA. Secretary, W. B. Brockway, 40 Morris Street, Yonkers, N. Y.

STREET RAILWAY ASSOCIATION OF THE STATE OF NEW YORK. Secretary, W. W. Cole, Elmira, N. Y. Next meeting, Utica, N. Y., Oct. 11 and 12, 1904.

UNITED ELECTRICAL CONTRACTORS' ASSOCIATION OF NEW YORK STATE. Secretary, F. Fish, Rochester, N. Y.

VERMONT ELECTRICAL ASSOCIATION. Secretary, C. C. Wells, Middlebury, Vt.

WESTERN SOCIETY OF ENGINEERS. Next meeting of Electrical Section, Chicago, March 18, 1904.

General News.

THE TELEPHONE.

MONTGOMERY, ALA.—The Middletown & Wellsville telephone line has been organized here, with Jeff Haygood as president.

JOLIET, ILL.—The building of the Chicago Telephone Company here has been destroyed by fire.

JOHNSON CITY, ILL.—The Good Service Telephone Company has been incorporated with a capital stock of $2500. The directors are J. E. Poindexter and others.

CHICAGO, ILL.—It has been officially stated that the Chicago Telephone Company will erect an eight-story building on Washington St., next to the Title & Trust Bldg., in which place its present exchange is located and which it has outgrown. It will be several months before the company issues any new stock, as the exchequer is well supplied with immediate funds.

LIBERTY CENTER, IND.—The Liberty Center Telephone Company has filed articles of incorporation. The capital stock is $2500. James P. Mounsey, L. A. Minnear and O. D. Garrett are the directors.

LANDESSVILLE, IND.—The Landessville Rural Telephone Company has increased its capital stock to $9975, for the purpose of making extensions and improvements. Henry Wine is president, and Rudy Freeman, secretary.

GREENFIELD, IND.—The Vernon Township Farmers' Telephone Company, of Hancock County, has filed articles of incorporation with the Secretary of State. The capital stock is $1000. George M. Rumler, John Hiday, C. J. Jackson and others are directors.

CONNERSVILLE, IND.—A stockholders' meeting of the Connersville Telephone Company was held in this city recently. The directors elected George M. Sinks president, W. T. Edwards vice-president, and L. A. Frazee secretary and treasurer. The secretary reported over 700 telephones in operation.

MARION, IND.—C. C. Huff, a country school teacher of this county, has used the telephone successfully in teaching absent pupils. For two weeks the family of James Hewitt has been quarantined because of small-pox in the family. Two of Mr. Hewitt's sons are anxious to graduate this year, and for them to miss school rendered this result doubtful. The teacher suggested the telephone. For two weeks Mr. Huff assigned the lessons to the lads and heard them recite each evening over the telephone. They are now back in school and well up with their class, due to the use of the telephone.

BALTIMORE, MD.—The Chesapeake & Potomac Telephone Company is rapidly installing new instruments in the burnt district. Fortunately for the company, it had a switchboard stored away in Washington. This is now installed and in working order. The Maryland Telephone & Telegraph Company was little harmed by the fire save in the loss of instruments and distributing poles in the burnt district. It is busy supplying telephones to all subscribers who have opened temporary offices.

HERMOSILLO, MEX.—A long distance telephone line is to be built between this city and Guaymas. A. Mascarenas, cashier of the Banco Sonora, Chihuahua, Mexico, can give information.

TORREON, MEX.—The Government has granted a concession to M. A. Sepulveda, of the Torreon Telephone Company, to extend its lines to the towns of Gomez Palacio, Lerdo and adjacent haciendas. The concession also authorizes the company to extend its lines to the cities of Durango, Monterey, Saltillo, Mapimi and other places. All of the principal towns and cities of northern Mexico are to be included in the proposed system.

ALPENA, MICH.—Mr. C. H. Reynolds has been elected president of the Alpena Mutual Telephone Company, and Mr. W. H. Johnson secretary and treasurer.

MONROE CITY, MO.—J. M. Griggsby, of Goss, president of the Monroe Mutual Telephone Company, met about 75 farmers in this city February 20 and formed a mutual company that will work in connection with the county lines.

CLAYTON, MO.—At a meeting of the directors and stockholders of the St. Louis County Telephone Company, in this city, it was decided to begin work on the new line within the next 30 days. The offer of telephones for $1 a month for residences and $1.50 a month for business establishments will be discontinued after March 14.

ST. LOUIS, MO.—At a meeting of the directors of the Bell Telephone Company of Missouri, February 23, Cyrus P. Walbridge was elected president to succeed F. P. Fish, of Boston. It is stated that Mr. Fish, who is president of the American Telephone & Telegraph Company, could not give his time to both organizations. The officers elected, besides Mr. Walbridge, were Edwards Whitaker, vice-president; Fritz Nisbet, secretary and treasurer, and George F. Durant, general manager. The following directors were elected at a previous meeting of the stockholders: Cyrus P. Walbridge, D. S. Smith, William Duncan, John A. Holmes, James Campbell, P. C. Maffit, F. P. Fish, Casper Yost, A. Bert, George F. Durant and Edwards Whitaker.

AVOCA, NEB.—A number of farmers here have formed a new company to be known as the Avoca Telephone Cobpany, No. 4.

LINCOLN, NEB.—The Phelps County Telephone Company has been incorporated with a capital stock of $40,000. The directors are C. W. Stiger and others.

PIKE, N. Y.—The Pike Telephone Company has been incorporated with a capital stock of $1000 by G. S. Van Gorden, Henry C. Lathrop and Fred W. Gild, Pike, N. Y.

ALBANY, N. Y.—The Big Eddy Telephone Company has been incorporated with a capital stock of $8000. The directors are: Frank Kinnie, G. W. Engleman and others.

JASPER, N. Y.—The Jasper & Canisteo Telephone Company has been incorporated with a capital stock of $300. The incorporators are: Willis A. Schency, Dr. Walter Benedict, Jasper; Ray Jamison, Canisteo.

ASHLAND, OHIO.—The Central Union Telephone Company will install an exchange at this place.

HICKSVILLE, OHIO.—The Hicksville Telephone Company has increased its capital from $25,000 to $40,000.

WARREN, OHIO.—The Phalanx & Leavittsburg Telephone Company is considering the extension of its system.

DAYTON, OHIO.—The Home Telephone Company, of Dayton, has increased its capital from $600,000 to $1,000,000.

WALDO, OHIO.—The Waldo Home Telephone Company has been incorporated with a capital stock of $25,000. The directors are A. Osborn and others.

GALLIPOLIS, OHIO.—A new telephone company has been organized in Green Township to connect with the Gallipolis Telephone Company. Among the stockholders are B. and E. Wadell and J. W. Ecker.

COLUMBIANA, OHIO.—The Fairfield Township Mutual Telephone Company is being organized to build an independent telephone system in Fairfield township. Farmers in the vicinity are interested in the enterprise. Among the promoters are: O. C. Vanskiver, Harvey Woods, John Wisler and J. W. Weaver.

CINCINNATI, OHIO.—The Cincinnati & Suburban (Bell) Telephone Company continues to show a substantial increase in its business, and the number of applicants for surface is still on the increase. The annual report, which will soon be forthcoming, will make an excellent showing. The company has been paying dividends of 6 per cent. per annum, but recently the stock has advanced from 140 to above 160.

TONKAWA, OKLA.—The Farmers' Mutual Telephone Company has been incorporated with a capital stock of $2500 to $10,000.

GUTHRIE, OKLA.—The Pioneer Telephone & Telegraph Company, with headquarters here, has been chartered to operate telephone lines and district telegraph or messenger systems. The capital stock is said to be $3,000,000. The company is a merger of several independent telephone companies in Oklahoma and Indian Territory.

PENDLETON, ORE.—The Wild Horse Telephone Company has been incorporated with a capital stock of $1000. The directors are W. M. Blakely and others.

WASHINGTON, PA.—The Buffalo & Hopewell Township Telephone Company has been formed, with J. H. Stewart as president.

INDIANA, PA.—About twenty farmers in the vicinity of Shelocta have formed a local telephone company. Wm. Rankin is president of the new company.

COLUMBIA, S. C.—A bill has been introduced in the legislature of South Carolina fixing a schedule of telephone rates for city and country on a basis of $1.50 for residences and $2 for places of business in exchanges of less than 250 subscribers, and $2.50 for residences and $3.50 for business houses in exchanges of 1200 subscribers or over, and a proportionate scale for intermediate size exchanges.

HUDSON, S. D.—The Hudson Telephone Company is contemplating building a large number of exchanges throughout the country districts during the present year. At a recent meeting of the stockholders the following named officers were elected: President, E. D. Cassil; vice-president, O. C. Olson; secretary, E. R. Buck; treasurer, F. B. Cable.

PORT LAVACA, TEX.—The Port Lavaca Telephone Company will make important improvements.

HOUSTON, TEX.—The Citizens' Telephone Company has extended its long distance telephone line to Sour Lake, Tex., from Houston.

BROWNSVILLE, TEX.—The Western Union Telegraph Company will extend its telegraph line from Corpus Christi to this place, a distance of about 175 miles.

AUSTIN, TEX.—The Southwestern Telegraph & Telephone Company announces that improvements to cost about $20,000 will be made to the local system of the company.

SOUR LAKE, TEX.—The Higgins Oil & Fuel Company has constructed a telephone line from this place to Batson, Tex., a distance of about 18 miles. It will be used for the private business of the company.

MENARDVILLE, TEX.—The Menard Telephone Company, of Menardville, has just completed a telephone line to Hext, a distance of 15 miles, and will soon commence the construction of a line to McKavill, Tex.

SAN ANTONIO, TEX.—Col. J. E. Farnsworth, of Dallas, Tex., announces that the Southwestern Telegraph & Telephone Company, of which he is manager, will expend about $80,000 in making improvements and extensions to its local system at San Antonio. Engineers are now preparing the plans for the proposed work.

LULING, TEX.—The City Council of Luling has granted a franchise to the Independent Telephone Company to establish and operate a telephone exchange here. It is announced by the officers of this company that it will immediately begin the construction of a long distance telephone line to connect San Antonio and Houston, a distance of 225 miles. Among the men interested in the company are: H. W. Flato, of San Antonio, Tex.; T. H. Spear, of New York, and George Cornelius, of Minneapolis, Minn.

MONTPELIER, VT.—The New England Telephone Company will build a new line from Burlington to Rutland.

ST. ALBANS, VT.—The independent telephone companies of northern and central Vermont held a meeting recently at St. Johnsbury and decided to build a trunk line from St. Johnsbury to Montpelier. It is the purpose of the independent companies to build trunk lines and ultimately reach all parts of the state.

GANDEVILLE, W. VA.—The Spencer, Gandeville & Weston Telephone Company has been incorporated with a capital stock of $75,000. The directors are: E. Johnson, L. A. Rader and others.

BARRON, WIS.—The Barron County Telephone Company has increased its capital stock from $2500 to $22,500.

ELECTRIC LIGHT AND POWER.

KEMPS CREEK, ALA.—A franchise for an electric plant has been granted to Frank F. Taylor.

EAST LAKE, ALA.—It is proposed to construct an electric light plant, at a cost of $10,000. Robt. A. Morris is chairman of the committee.

ANNISTON, ALA.—The Coosa Water Power Development Company, of Anniston, has been chartered, with a capital of $250,000, to develop the water power of Coosa River for the benefit of Anniston, Pell City and other places.

BIRMINGHAM, ALA.—The City Council and the citizens of the west end are considering the construction of water works and an electric light plant.

DARDANELLE, ARK.—Bonds to the amount of about $7000 will be issued for the construction of an electric light plant.

FORDYCE, ARK.—The Fordyce Light & Water Company has been chartered with a capital of $20,000. It will furnish lights for the town and factories. B. H. Wood, president; John R. Hampton, secretary.

ALHAMBRA, CAL.—The Pacific Light & Power Company, Los Angeles, has secured the electric light franchise.

FERNDALE, CAL.—W. W. Barnes, secretary of the Ferndale Electric Light Company, writes that about $8000 will be expended in improvements.

CORONA, CAL.—The Temescal Water Company, of this place, is making extensive improvements. It is building laterals and digging wells. One of the largest improvements is an electrical transmission line in course of construction between Ethanac and Temescal, 20 miles. At Ethanac the company has a number of good wells, heretofore pumped with gasoline and steam engines, requiring large quantities of oil and distillate, which had to be hauled 20 miles from Corona at heavy expense. Now the pumps will be driven by electric motors. The workmen building the electric line will have a comfortable house on wheels in which to live. Poles have been ordered from Washington State, and it is expected the line will be in operation in six weeks. The improvements will cost $15,000.

DELAWARE CITY, DEL.—W. T. Smith, Mayor, writes that it is proposed to construct a lighting plant.

JONESBORO, GA.—The citizens have voted to issue bonds for an electric light plant.

DOUGLAS, GA.—Bids will be received March 7 by C. E. Baker, City Treasurer, for $20,000 electric light and water bonds.

BUENA VISTA, GA.—Geo. R. Lowe, Recorder, states that the town is contemplating letting a franchise for an electric light plant.

COVINGTON, GA.—The development of two important water powers near Covington, on Alcova River, is said to be practically assured. N. S. Turner, W. C. Clark and C. H. White are the incorporators of a company which expects soon to begin the work of development of the two falls. Thirty thousand dollars have already been subscribed to the stock of the company, and this sum will be considerably increased. The water power available is said to be 14,000 horse-power. It is proposed to supply energy for lighting the city of Covington and for operating the Covington & Oxford Street Railway and other plants.

LENA, ILL.—The business men are considering the construction of an electric light plant.

KIRKWOOD, ILL.—A franchise for an electric light plant has been granted to the Kirkwood Electric Company.

VIRDEN, ILL.—The Virden Electric Light Company, of Virden, has been incorporated, with a capital of $15,000. Incorporators: J. N. Hairgrove, U. G. Tucker and C. W. Carr.

CICERO, IND.—The Town Board is taking steps toward constructing an electric light plant.

NEW HAVEN, IND.—The Town Trustees have decided to construct an electric light plant.

INDIANAPOLIS, IND.—The Indiana Supreme Court has decided that the franchise granted by the town of Booneville to the Booneville Electric Light & Power Company for laying pipes, putting up poles and wires to supply light, heat and power, is void, because the ordinance was never published as provided by statute. It is now probable the company will be enjoined from further service until a new franchise is procured.

LEWISTON, IDA.—The Lewiston Water & Power Company has determined to develop the water power near the mouth of Grand Ronde River. The improvement will cost about $1,000,000. The company also proposes increasing the capacity of its present plant from 1200 to 2000 horse-power.

WALNUT, IA.—Bids are being received for furnishing material and constructing a complete electric light and power plant here. A. R. Longnecker is Town Clerk.

OGDEN, IA.—Bids will be received on March 15 for an electric light plant of 1800 lights, a gas plant of 1800 lights, and a combined gas and electric plant. Address City Recorder.

FT. DES MOINES, IA.—Bids will be received by Maj. R. B. Turner, Q. M., U. S. A., Observatory Office Building, Des Moines, on March 16 for an electric lighting system at Ft. Des Moines.

YATES CENTER, KAN.—It is reported that the Council wishes to grant franchises to a private company to establish electric lighting at this place.

WEST GARDINER, ME.—Jas. Carver and A. L. Childs, of Auburn, are among those interested in a proposed electric power enterprise, on Cobbossee stream at Cram's Mills in West Gardiner, and about two miles below the outlet of Lake Cobbosseecontee. The new owners will increase its capacity from 350 to 500 horse-power by raising the dam. They propose to sell power in Augusta, Hallowell and Gardiner.

MERRIMAC, MASS.—It was voted on January 30 to construct an electric light plant.

NEGAUNEE, MICH.—Rockwell Bros. are to construct a new gas and electric plant at Negaunee.

SOUTH STILLWATER, MINN.—The question of issuing bonds to the amount of $10,000 or $15,000 for an electric lighting plant will be voted on the second Tuesday in March.

CULIACAN, MEX.—Bids are wanted March 31 for constructing an electric light plant. Address Senor Gen. Don Francisco Canedo, Culiacan, Sinaloa.

SAN CRISTOBAL, MEX.—Henry T. Lecert, representing a New York syndicate, is investigating the situation here with the view of establishing an electric light and power plant.

VILARDENA, MEX.—An electric power plant to cost about $50,000 is to be installed here by the American-Mexico Mining & Development Company to furnish power for the machinery at its mines. Dr. W. S. Phillips, of Chicago, Ill., is president of the company.

IRAPUATO, MEX.—An electric power plant will be installed here by Richard A. Barkley for the purpose of furnishing power to operate his four large flour mills, paint works and other industrial concerns.

SAN MIGUEL ALLENDE, MEX.—Jose de J. Garcia has been granted a concession by the Mexican Government to establish an electric power plant on the Laja River near here. He is authorized to use 1500 liters of water per second for the purpose.

TAMASOPA, MEX.—The Rio Tamasopa Sugar Company will install an electric light and power plant on its large plantation, situated near here. The plant will also furnish power for operating an electric freight railway on the plantation. Among those interested in the company are: Dr. John D. Cattic, of Anderson, Ind.; C. A. Smart, of Wild Rose, Wis., and Col. Russell B. Harrison, of Indianapolis, Ind.

COLUMBIA, MO.—A bond issue of $10,000 was voted February 23 for the purchase by the city of Columbia of the water works and electric light plant owned by the Columbia Water & Light Company, which holds the franchise for the supply of water and light to the town. The plant will be purchased for $67,000, and will be improved.

LEXINGTON, NEB.—Bids are wanted for a franchise for an electric light plant.

FREMONT, NEB.—It is reported that the municipal light station will be enlarged by an addition 30x60 ft., in which machinery will be installed, at a cost of $8000.

OXFORD, N. C.—A proposition has been made to the town to put in electric lights and water works, the town to rent the same.

CHARLOTTE, N. C.—The Light Committee has recommended that the city make a contract with the Catawba Power Company, of Ft. Mill, S. C., to supply lights at $54 per year for the first 150 lights and $48 for all over that number.

HARRISON, N. J.—The Town Council has granted a franchise to the United Electric Company to lay underground conduits in Harrison.

ANADARKO, OKLA.—The citizens have voted to issue bonds for the construction of an electric light plant.

KINGSTON, ONT.—The water power at Kingston mills on Rideau Canal has been secured by J. M. Campbell, and he will install an electric plant. A well to permit a fall of 52 ft. will be constructed.

PENDLETON, ORE.—By the filing of a notice of water appropriation at Pendleton, February 8, the Northwestern Gas & Electric Company, of Walla Walla, Wash., took the first step toward carrying out its plan of constructing a power plant on Walla Walla River near Pendleton. The company will furnish electric power for heating and manufacturing purposes in Walla Walla, Pendleton, Athena and other towns.

MT. UNION, PA.—It was voted February 16 to issue $12,000 bonds for an electric plant.

WILKESBARRE, PA.—The Select Council has granted a franchise to the Ashley Electric Light Company. It refused to grant a franchise to the West Side Electric Light Company.

NEW CASTLE, PA.—Robt. Hunt & Company, of Pittsburg, have submitted plans and estimates for a municipal electric light plant. They estimate the cost of buildings, equipment, etc., at $65,415, and cost of operation, $18 per day.

SHIPPENSBURG, PA.—It is stated that arrangements are being perfected for the merging of the Shippensburg Gas Company and the Electric Light & Power Company into the Shippensburg Heat, Light & Power Company. The electric power will be furnished by water about two miles distant from the borough.

STEWARTSTOWN, PA.—The directors of the recently chartered Deer Creek Water & Power Company organized in Stewartstown on February 13, with Jas. H. Gable, of York, president. The company proposes to construct a dam and power plant on Deer Creek, one mile from Stewartstown, and when completed will furnish water, power and light to Stewartstown and vicinity.

LEXINGTON, S. C.—The State Senate has passed the bill authorizing the Lexington Power Company to build dams across Saluda River.

GROTON, S. D.—Herman E. Miles, of St. Paul, Minn., has secured a franchise for an electric light, gas and central heating plant.

COLUMBIA, TENN.—The Louisville & Nashville Railroad Company intends to build a water power and electric light plant at Bigby Creek. The expenditure involved will be between $12,000 and $15,000.

COLUMBIA, TENN.—Bids are wanted for building and equipping an electric light plant to furnish the city with lights. It is desired to let contracts for 60 arc lights, and at end of the term a further satisfactory contract to be entered into, or the plant is to be sold to the city at an appraised valuation. It is contemplated that this plant shall also furnish incandescent lights to private parties. W. A. Dale is chairman of the Light Committee.

PORT LAVACA, TEX.—C. J. Spettae, of Panhandle, Tex., is arranging to install an electric light and power plant at this place.

UVALDE, TEX.—An eectric light plant is to be installed here by W. H. Rose. He also contemplates building a street railway here.

HARDWICK, VT.—This village contemplates increasing the power for its electric light plant.

ELLENSBURG, WASH.—Bids are wanted March 7 for an electric light plant. It is to be operated by turbine wheels of 640 horsepower, and 240-kw dynamos will be installed. Estimated cost, $22,000.

SPOKANE, WASH.—A power company which proposes to utilize the waters of the Spokane River about 20 miles from here in the Big Bend territory, for furnishing electric lights, will shortly be organized here. A 20,000-hp plant will be established, from which electrical energy will be furnished to the large flour mills at Big Bend and for the lighting of numerous small cities in that vicinity. Surveys have already been made, and the route of the pole lines to Spokane was decided upon some months ago. David Wilson is the chief promotor of the enterprise, and has made all necessary arrangements in the east whereby work can be commenced in the very near future. At the point where it is proposed to establish the power plant, a fall of 33 feet can be utilized. Eastern investors will furnish most of the capital for the enterprise.

MONTICELLO, WIS.—A municipal electric light plant is proposed here.

EAST MILWAUKEE, WIS.—The Milwaukee Light, Heat & Traction Company, of Milwaukee, has petitioned for a franchise to light the village.

BELOIT, WIS.—Bids were called for March 3 for the construction of an electric light plant, to cost between $30,000 and $40,000. D. H. Foster is City Clerk. Robert Caldwell, City Engineer.

RHINELANDER, WIS.—The Rhinelander Power Company, of Rhinelander, has been incorporated, with a capital of $85,000, by E. A. Forbes, C. A. Wixson, R. C. Dayton and others, to improve and develop water power in the Wisconsin and other rivers.

NEENAH, WIS.—The Wisconsin Traction, Heat, Light & Power Company, operating the electric interurban line between Neenah and Kaukauna, has petitioned the City Council for a franchise to light the city. The company offers to furnish street lights at $65 per year on an all-night schedule.

THE ELECTRIC RAILWAY.

CHICAGO, ILL.—There is to be a meeting of the stockholders of the South Side Elevated Railroad Company on April 7, to vote on the question of increasing the capital stock to carry out the plans for extensions, as outlined by President Carter at the recent annual meeting.

VINCENNES, IND.—The Vincennes, West Baden & Louisville Traction Company has asked for a $50,000 subsidy, and an election has been ordered for March 12.

LEXINGTON, KY.—O. M. Baker, of Hamilton, O., and George Nowall, of Cincinnati, have taken the contract for building the line of the Paris & Georgetown Traction Company, between Franklin and Versailles.

BANGOR, ME.—Surveys are now being made for the proposed electric railway from Bangor to Dexter, Me., and it is expected that construction work will be begun on the line this summer. The line will be 30 miles in length. The overhead trolley will be used. Power to operate the line will probably be developed from water sources. The officers of the company are: H. F. Bailey, of Bangor, president; E. B. Weeks, of Old Town, treasurer; F. J. Martin, of Bangor, attorney and clerk; F. T. Dow, of Bangor, engineer.

AUGUSTA, ME.—The Northern Main Seaport Railroad Company has been incorporated to build an electric railway from a point in connection with the Bangor & Aroostook Railroad at La Grange, to a point in connection with the Maine Central Railroad near the northwest line of the city of Belfast, with two spurs or branches to tidewater, one in Stockton Springs and one in Searsport. The length of the road is to be 60 miles, and the company is capitalized at $360,000. The directors are: Edward Stetson, B. B. Thatcher, F. H. Appleton, F. W. Cram and H. P. Oliver, of Bangor.

ST. LOUIS, MO.—The Alton, Granite City & St. Louis Electric Railroad has been organized at Alton, with a capital of $100,000. The organizers are: J. F. Porter, W. E. Porter, H. S. Baker, H. E. Weeks and Levi Davis.

KANSAS CITY, MO.—A franchise has been granted to the St. Joseph, Parkville & Kansas City Railway Company for an electric railway through this county from Harlem to the Platte County line.

KANSAS CITY, MO.—The Kansas City & Olathe Electric Railway Company has awarded the contract for the construction of its power plant to the Union Construction Company, of Kansas City. The plant will be located at Lackman, Kan.

NEW YORK, N. Y.—The name of the Interurban Street Railway Company has been changed to New York City Railway Company.

ADA, OHIO.—Thomas C. Childs, of Akron, has obtained a franchise in Ada for the line which will be built from Lima to Kenton.

DAYTON, OHIO.—The Interstate Traction Company has applied for a franchise in Montgomery County for a proposed line from Dayton to Indianapolis.

CLEVELAND, OHIO.—The Eastern Construction Company has closed a contract for building the line of the Warren, Courtland & Jefferson Traction Company.

CANTON, OHIO.—The Canton-Akron Railway Company is in the market for a 600-hp boiler, six 12-bench open cars, six 18-ft. box cars with 67 motors and all other parts necessary to complete cars.

NEW INDUSTRIAL COMPANIES.

THE H. O. S. ENGINEERING COMPANY has been incorporated in New York with a capital of $15,000. The directors are: J. A. Aitkin, W. H. Brearley and W. A. Thompson, of New York.

THE JORDAN AUTOMATIC SIGNAL COMPANY of New York has been incorporated with a capital stock of $1,000,000. The directors are: W. H. Jordan, C. C. Jordan and J. F. Jordan, New York.

RADIUM INCANDESCENT LIGHT COMPANY of New York, with a capital stock of $15,000, is of recent corporation. The directors are: J. Perk, Brooklyn; S. Wolfson and I. Wigdor, New York.

THE UNITED ELECTRICAL MANUFACTURING COMPANY has been incorporated in New York with a capital stock of $1000. The directors are: E. F. Buchanan, A. O. Brown and L. G. Young, New York.

THE PHYSICIANS' ELECTRICAL MANUFACTURING COMPANY of New York has been incorporated with a capital stock of $10,000. The directors are: F. E. Hodgskin, G. A. Wingate and A. B. Reed, New York.

THE GENERAL LIGHTING & HEATING COMPANY of New York has been incorporated with a capital stock of $20,000. The directors are: Stanley Francis, W. A. Smith and G. D. Moffatt, New York.

THE WATSON-FLAGG ENGINEERING COMPANY of Paterson, N. J., has been incorporated with a capital stock of $125,000. The incorporators are: George H. Watson, John L. Flagg and Frank J. Huttin.

THE MUNICIPAL ELECTRIC & CONSTRUCTION COMPANY has filed articles of incorporation with a capital stock of $50,000. The incorporators are: Charles G. Diemunch, William Gottlieb and Joseph Block.

THE CHARLES Q. TYSON COMPANY, of Dayton, O., electrical contractor, has been incorporated with a capital of $10,000, by P. W. Tyson, C. O. Waxler, H. H. Wolloston, G. W. Chaffin and R. W. Baggott.

THE WESTERN RAILWAY SIGNAL COMPANY has been incorporated at Camden, N. J.; capital, $60,000. Incorporators: John G. Bennett, Walter C. Beckworth, Philip Peter, Joseph H. Phillips and Josh B. Chapman.

THE NEW YORK F. E. COMPANY has been incorporated to deal in electrical supplies. The capital stock is $1000, and the directors are: W. H. McClain and C. L. McFetrish, New York; Edward Butcher, Jr., Brooklyn.

THE FALLER AUTOMATIC TELEPHONE EXCHANGE COMPANY of New York has been incorporated with a capital of $10,000. The directors are: J. W. Chisholm, E. A. Faller, New York; Clarkson Clothier, Philadelphia.

THE WITHERBEE IGNITER COMPANY has been incorporated in Jersey City with a capital stock of $50,000. The incorporators are: Thomas S. Witherbee, Albert E. Milliken, Mervyn A. Rice, Thomas Mullally.

FAURE-PRICE ELECTRIC COMPANY has been incorporated in New York with a capital stock of $25,000. The directors are: J. P. Faure, New York; E. A. Watson, Brooklyn, and E. H. Price, Rutherford, N. J.

THE MONTEREY LIGHT & POWER COMPANY has been incorporated in Jersey City, N. J., with a capital of $50,000. The incorporators are: K. K. McLaren, Jersey City; Robert L. Hoguet and Robert H. Williams, New York City.

THE LIEBER-FOYE AUTOMOBILE COMPANY, of St. Louis, Mo., has filed articles of incorporation with a capital stock of $4000, full paid. The incorporators are: William B. Foye, Otto Lieber, Miss Ida E. Foye and Paul V. James.

THE POLYPHASE IGNITION SYSTEM COMPANY, of New York City, has been incorporated to deal in electrical machinery. The capital stock is $50,000, and the directors are: R. L. Heitemeyer, Hoboken, N. J.; G. G. Schreiber and W. B. Symmes, New York.

THE AUTOMOBILE TRANSIT COMPANY, of St. Louis, has filed articles of incorporation with a capital stock of $12,500, full paid. The incorporators are: O. P. Langan, A. G. Lewis, G. F. W. E. Eggert, L. B. Langan, C. H. Cuncker, A. D. Anderson and Myron Peers.

LEGAL.

THE CHICAGO MOTOR VEHICLE COMPANY has, according to press dispatches from Chicago, been placed in charge of a receiver by Judge Tuthill, of the Circuit Court. The action was taken on the application of two stockholders who, it is stated, claimed that they would be defrauded if a proposed plan to divert the assets of the company were carried out. Mr. Edwin S. Day was appointed to take charge of the company's affairs.

INDEPENDENT TELEPHONY IN NEW YORK.—The Appellate Division of the New York Supreme Court handed down a decision affirming an order by Justice Clarke at Special Term denying a motion for a peremptory writ of mandamus asked for by the Independent Telephone Company, of New York, to compel Robert Grier Monroe, then Commissioner of Water Supply, Gas and Electricity, to issue a certan permit. The company had asked for a permit to lay and maintain telephone wires in the low-tension subway and have additional subways of the kind constructed in various localities. Commissioner Monroe refused to grant the permit on the ground that he had been advised that the company had no franchise or right to construct and maintain such structures and fixtures as were asked for. The order denying the motion was affirmed by the Appellate Division, but without opinion. Justice Laughlin dissents. In a brief opinion he says: "The transportation corporation law, under which relator was incorporated, gives it a franchise, and it is, without obtaining any further franchise from the Municipal Assembly, in a position to apply to the respondent for a permit pursuant to the provisions of Section 528 of the Greater New York charter, which must be entertained and granted upon such reasonable terms, conditions and restrictions as may be imposed by the respondent, pursuant to any provisions of law applicable thereto."

FESSENDEN LIQUID BARRETTER PATENT. The National Electric Signalling Company has brought suit in the United States Circuit Court, Southern District of New York, against the DeForest Wireless Telegraph Company, the American DeForest Company, Abraham White, president of said companies, and Lee DeForest, scientific director, for infringement of Reissue Letters Patent No. 12,115, of May 26, 1903, to Reginald A. Fessenden. This patent is for the well-known liquid barretter or receiver for wireless telegraphy, and describes the liquid barretter as having resulted from the discovery that when a loop of the Fessenden solid barretter or hot wire receiver is broken while dipping in nitric acid it works even better than before. In this case the resistance change is a decrease instead of an increase, and it is localized in the minute layer of the liquid next to the wire, instead of in the wire. The patent mentions a platinum wire forty one-millionths of an inch in diameter dipping into dilute nitric acid or other conducting liquid. For six months this receiver has been used by the National Electric Signalling Company, transmitting 20 regular messages a day each way over 80 miles of land between their stations at Jersey City and Collingswood, a suburb of Philadelphia. This has been accomplished with transmitting apparatus using a quarter of a horse-power of electrical energy, and in recent tests this has been cut down to a tenth and even a fifteenth of a horse-power. Professor Fessenden claims to have patented this invention more than nine months ago, and it was fully described in the technical press in September, 1903. (See ELECTRICAL WORLD AND ENGINEER, New York, September 19, 1903, page 272.)

OBITUARY.

MR. S. B. FAIRCHILDS.—Mr. Sidney B. Fairchilds, one of the oldest telegraphers in the United States, and father-in-law of Frederick MacMonnies, the sculptor, died at St. Louis on February 27, aged 72. Mr. Fairchilds had been employed by the Western Union Telegraph Company in that city for 39 years, and for many years had been night wire chief. In point of age and service he was the oldest member of the telegraphers' association known as "The Old-Timers."

MR. W. G. McMILLAN.—We regret deeply to note the death from pleurisy of Mr. Walter George McMillan, the secretary of the Institution of Electrical Engineers of England, an office he had held with great acceptance since 1897. He was educated at King's College, London, where he also taught metallurgy, in which he lectured later at Mason College, Birmingham. He served also as a Government chemist and metallurgist, and at the time of his death was an examiner in metallurgy for the City & Guilds of London Institute. He was only 43 years of age. He has left a widow and two young sons, and the Council of the Institution has now started a memorial fund, which will be invested for the benefit of his widow and for the education of these fatherless boys. American visitors will recall Mr. McMillan's quiet and unremitting efforts in 1900, to promote their welfare and comfort during the foreign trip of the Institute.

EDUCATIONAL.

LYNN GENERAL ELECTRIC ENGINEERING SOCIETY, of Lyon, Mass., is carrying out a splendid programme of papers and visits this winter, with meetings about once a month regularly, and other specialties interspersed. Dr. F. A. C. Perrine has just lectured on "Electricity from the Waterfall," and Prof. H. E. Clifford is down for a special course on alternating-current theory. The Society, which is thus doing excellent work, is composed principally of the engineers of the General Electric Lynn Works, together with students from the testing department.

COLUMBIA RADIUM EXHIBIT.—Because of the importance and interest attaching to the recent discovery of radium, Columbia University is planning a special exhibit at the St. Louis Exposiion. Mr. F. A. Goetz, superintendent of the university buildings and grounds, will have charge of the enterprise, which will also include an exhibition of the Mineralogical Department. This will show various phases of producing radium. Dr. Tucker, of the Chemical Department, will have charge of the chemical side, and Professor Hallock will superintend the physical, including the methods and the illustrations of radio activity. The Pathological Department of the College of Physicians and Surgeons will give illustrations showing its usefulness in medicines.

PERSONAL.

MR. W. B. PARSONS, M.E., engineer of the New York Subway, has been appointed by President Roosevelt a member of the Panama Canal Commission.

MR. R. H. COKER, formerly of Washington, D. C., has been appointed agent of the Colorado Telephone Company at Longmont, Col., succeeding Mr. C. F. Bartell.

MR. H. F. GREENWOOD, chief engineer and special manager of the Havana Electric Company, is now in New York. He may be found at the local offices of the company, 52 Broadway.

MR. M. E. CURWEN, European representative of the J. G. Brill Company, of Philadelphia, whose headquarters are in London, has sailed for the other side, after a short visit to this country.

DR. MARGARET A. CLEAVES has issued in pamphlet form her article on the physiological action of light and the physical factors in phototheraphy printed recently in the *Journal of Advanced Therapeutics*.

MR. J. C. BOYNTON has been appointed manager of the Toll Department of the Colorado Telephone Company, with headquarters in Denver. He was previously traffic manager of the Pittsburg Telephone & Printing Company.

MR. HARRY ALEXANDER, of New York City, has opened an office in Boston at 120 Tremont Street, to conduct an electrical contracting business. He is now engineering the electrical work on the new Siegel Building in Boston.

MR. F. J. ALVIN, of the American Electrical Novelty & Manufacturing Company, 308-322 Hudson Street, New York City, has been elected president of the recently formed Foreign Trade Association of America, 66 Broad Street, New York City.

MR. GEORGE BULLOCK, president of the Bullock Electric Manufacturing Company, of Cincinnati, Ohio, who has recently been somewhat seriously indisposed, returned this week from Bermuda, where he has been recuperating for a few weeks.

MR. HENRY SHAFER, president of the International Telephone Manufacturing Company, of Chicago, has been making an extended trip through the Northwest in connection with the growing work of the company in that large and important section

MR. J. R. LOVEJOY, the head of the electric lighting department, etc., of the General Electric Company at Schenectady, has found it necessary to drop business for a brief rest and has been visiting Hot Springs, Va. His vacation, however, will not be a very long one.

MR. W. A. BRACKENRIDGE, C.E., of the Niagara Falls Power Company, has been appointed by Governor Odell, of New York State, a member of the special advisory commission of five expert engineers who will supervise the construction of the $100,000,000 barge canal.

MR. O. M. C. HEYL will have charge of a new electrical department to be inaugurated by Paul Bergner & Company, Mexico City, in order to cater to the increasing demand for electrical appliances and supplies which has lately sprung up throughout the southern republic.

MESSRS. H. HOBART PORTER, JR., and FRANCIS BLOSSOM, of Sanderson & Porter, New York, have returned from a trip to New Orleans, where they recently went in connection with the proposed power house extension of the New Orleans Railways Company.

MR. THOMAS A. EDISON went South last week and has taken up residence on his plantation near Fort Myers, Fla. He has telegraphed his friends that the orange and lemon trees are in full bloom, which is taken as an intimation that he proposes to drop work for a brief spell.

BELLMAN & SANFORD, New York City, have been appointed engineers by the American Exchange National Bank to prepare plans and specifications for a lighting plant, to be installed in their 16-story bank and office building, corner of Broadway and Cedar Street, New York City.

MR. JAMES I. BUCHANAN, who returned recently from Panama, where he went on a special mission for the United States Government, has sailed for Europe to assume his new position as deputy chairman and managing director of the British Westinghouse Electric & Manufacturing Company, Limited.

MESSRS. T. AHEARN and W. Y. SOPER are the subjects of portraiture and of biographical sketches in connection with an article in the Ottawa *Evening Journal* on the Ottawa, Can., street railway system, which they have built up, in addition to doing a lot of other creditable electrical work all over the Dominion.

MR. FRANK KLEPETO, consulting engineer, New York, has sailed for Peru in reference to the construction of the huge smelting works, etc., of the Cerro de Pasco Mining Company, in which enterprise J. B. Haggin is the moving spirit. Considerable electrical equipment will be purchased within the next few weeks.

MR. CLEMENS HERSCHEL, formerly hydraulic engineer of the Holyoke, Mass., Water Power Company, also consulting hydraulic engineer from time to time during the past score of years of several Niagara water power companies, will have charge of the new water turbine and other hydraulic machinery department of the Allis-Chalmers Company.

MR. ABNER DOBLE, of Abner Doble Company, San Francisco, the pioneer railroad engineer, etc., on the Pacific Coast, has had the misfortune to lose his wife, who accompanied him to the State in 1851. Mrs. Margaret Doble was 73 years old, and leaves four adult children. She and her husband had as Argonauts seen all the wonderful growth of California.

MR. H. D. SCRIBNER, who has been prominently connected with the Westinghouse Electric & Manufacturing Company's Pacific Coast agencies for a number of years, has left San Francisco and opened an office of the Canadian Westinghouse Company in Vancouver, B. C. Mr. Scribner has done much of the early and recent electric railroad building on the Pacific Coast.

MR. E. RATHENAU, as already noted in these columns, has been decorated with others by the Emperor of Germany in connection with the Zossen high-speed electric railway work. This honor has given great pleasure to his host of friends and admirers in America. We understand that the decoration conferred is that of the Order of the Red Eagle, with the clasp.

MR. ERNEST F. LEARNED, formerly with Stone & Webster, of Boston, has arrived in Denver on an extensive vacation tour of the United States. Mr. Learned plans to visit California and Washington before returning east, and he accompanied Mr. C. F. Wallace, of the Stone & Webster management, as far as Chicago, Mr. Wallace going through to Seattle.

MR. S. G. McMEEN, of Chicago, Ill., is in the City of Mexico making preliminary arrangements for the extensions and improvements of the telephone system of the Mexican Telephone Company. This company recently obtained a renewal of its concession from the Mexican Government for a period of 30 years, and under the terms that it was granted certain stipulated improvements are required to be made.

MR. JAMES A. CUMMINGS, who secured the contract for the supplying and laying of the conduits for the new municipal telephone and telegraph lines now under construction in St. Petersburg, Russia, has sailed for Europe after several weeks' visit on this side. The conduit is being manufactured at the Raritan River, N. J., plants of the American Vitrified Conduit Company, Broadway-Maiden Lane Building, New York.

MR. J. L. PUTNAM, who for some years has been general manager of the Clark Automatic Telephone Switchboard Company, of Providence, R. I., and whose personal efforts have resulted in the installation of this system all over the country, has resigned his position to accept one with the Central Union Telephone Company, at Indianapolis, Ind. Mr. Putnam goes to his new work with the best wishes of all his friends, of whom he has a goodly number all over the country.

MR. W. J. HAMMER is out in Colorado and is understood to be making radioactive tests on pitchblende there. Dispatches from Denver speak of his handling pitchblende from Gilpin County, Colorado, where hundreds of tons are in sight at this moment, of high testing quality. Mr. Hammer delivered a lecture on February 26 in Denver, before the Colorado Scientific Society. His subject was "Radium." The lecture was given at the Central Presbyterian Church.

MR. ARTHUR WARREN contributes to the New York *Times* of February 28 a most charming and entertaining article on the "publicity" methods by which a great modern industry can be built up. While no names are given, it is of course an open secret that the Westinghouse interests are those dealt with in this instructive sketch. A number of excellent points are made, and none the less for being presented in admirable literary form. Mr. Warren's story deals with achievement on both sides of the Atlantic. Until quite recently, Mr. Warren had charge of the Westinghouse Publicity Bureau, but resigned to take up other important work.

MR. OSCAR T. CROSBY, the well-known electrical engineer, who penetrated recently to the interior of Thibet, has just returned home to this country. While in England he lectured by invitation before the Royal Geographical Society on his interesting journey. Since his return here, a number of his friends in the American Institute of Electrical Engineers and the New York Electrical Society have united in a formal request to him to give them an evening in New York, when they can listen to the tale of his adventures in that mysterious central region of Asia. It is understood that Mr. Crosby will gratify this wish at an early date.

MR. I. A. BENNETT, general sales manager for the Electric Appliance Company, Chicago, has resigned his post to take effect March 1, and will open the Chicago offices of the Phelps Company, of Detroit, Mich., manufacturers of the Hylo turn-down lamps and other specialties. Mr. Bennett was with this company for about 11 years, having previously been connected with the Ansonia Electric Company. Mr. Bennett has also accepted the presidency of the Central Station Publishing Company, which is being formed for the promotion of central station advertising. His new offices will be located in the Monadnock Building, Rooms 529 and 530.

MR. W. H. COVERDALE.—W. H. Coverdale & Company have recently been incorporated to do a general engineering and contracting business, with offices at 66 Broadway, New York. Their organization includes engineers of experience in all matters relating to the design and construction of steam and electric railroads, lighting and power plants, coal and ore handling machinery, etc. Mr. Coverdale was for many years in the engineering department of the Pennsylvania Lines West of Pittsburg, and was track elevation engineer of that company in Chicago during 1898-99. He was also prominently identified with the construction of the Westinghouse shops at East Pittsburg, and for the last three years has been civil engineer for a New York firm of engineers and contractors. Mr. Charles F. Keene is the secretary of the company.

MR. HENRY C. PAYNE.—Postmaster-General Henry C. Payne denies the imputation of the Wisconsin Independent Telephone Association that he has discriminated against the independent companies in favor of the Bell Company. In a letter to E. A. Wadhams, who is a trustee of the Standard Telephone Company, of Madison, Mr. Payne states that a large number of Bell telephones have been displaced from postoffices by the order, as well as independent telephones. "Each case is taken up on the merits as presented," he said. "You can readily see that long-distance service is a factor, and I think that I am justified in assuming that double service paid for by the Government is unnecessary and the expenditure not justified. Double service in all the postoffices in the United States would cost the Government an enormous amount of money, which I think would not be good business administration."

MR. A. H. VAN CLEVE.—The official anouncement of the appointment of Mr. A. Howell Van Cleve to be resident engineer of the Niagara Falls Power Company and its allied companies has been made by Vice-President Rankine. Mr. Van Cleve will succeed Mr. William A. Brackenridge, who has resigned to accept the appointment as a member of the Advisory Canal Board, recently tendered him by Governor Odell. Mr. Van Cleve has been connected with the engineer corps of the Niagara Falls Power Company continuously since April, 1892, and at the time of his appointment as resident engineer to succeed Mr. Brackenridge he held the position of assistant engineer. He is a graduate of Lehigh University, a member of the class of 1890, with the degree of C.E. Before his connection with the Niagara Falls Power Company he had served on the engineer corps of the Lehigh Valley and the Brooklyn Elevated railroads. He is a member of the Board of Public Works of Niagara Falls.

DIRECTOR OI.—The following item from the Pittsburg *Dispatch* deals with a man well known and admired in this country, and throws light on the progressive methods by which the Japanese have brought themselves abreast of the civilization of Europe and America: "Away back in the early '80s," said a well-known electrician of this city, "there came to me with a letter of introduction from the president of the company, a young Jap, and the note directed me that he be given every opportunity to work in all the departments of the factory, so that he might be proficient in every branch. He was apt, willing, always wore a grin and remained at the place about two years. The boy had been working as a lineman before he appeared at the factory. His name was Oi. He went back to Japan, and only at Christmas time, by a present, was the electrical engineer reminded of him. Many years later the engineer was waited upon by three Japanese who wanted to know all about the very latest devices for telephones and telegraphs. They were electrical engineers and had been taught all they know at the Imperial University in Tokio by a Prof. Oi, from whom they carried a letter of introduction to the engineer. They were Imperial Commissioners, and the engineer took them all over this country explaining things. The brightest of the three was called Wadachi and the others were Nakayama and Okonoto. They told their mentor that Oi was now Minister of Posts and Telegraphs in Japan, and this important position he now holds during war times." The many friends of Prof. Oi in this country know he will not be found wanting in emergencies.

Trade Notes.

THE MAINTENANCE COMPANY, of New York City, has removed its general offices to 54 and 56 Franklin Street.

THE J. B. McKEAGUE COMPANY, which is the Chicago representative of the Empire Electrical Instrument Company and F. A. La Roche Company, has recently changed its address to 324 Dearborn Street, Chicago, Ill.

PRATT & VAN WINKLE, the consulting engineers, of 160 Fifth Avenue, New York City, have issued a neat bulletin as to the merits and special advantages of the Pratt elevator safety for which they are agents. It is illustrated in detail.

THE ELECTRIC APPLIANCE COMPANY, Chicago, has just issued a folder picturing and describing the Greenwood safety wire guard for which it is selling agent. It claims that this guard has many features of value to any electric light man and contractor.

EMPIRE INSULATING CLOTHS AND PAPERS.—The Mica Insulator Company, 218 Water Street, New York, has issued a booklet containing samples of its varied line of Empire insulating cloths and papers. Each sample is accompanied by data relating thereto.

ROTARY PLANERS.—An excellent catalogue has been issued by the Newton Machine Tool Works, Philadelphia, on their rotary planers. These rotary planing machines are built in 11 sizes with heads from 14 inches to 84 inches in diameter over tools. They are built either fixed, portable or on a round base, and either belt or motor driven. Some excellent half tones show the construction of these machines.

H. T. PAISTE COMPANY, Philadelphia, Pa., has issued a neat circular with a view of the Government Printing Office, Washington, D. C., recently described in these pages, and calls attention to the fact that it supplied for that plant no fewer than 16,000 P. K. sockets and 10,000 P. K. fusible ceiling rosettes. These were essentially of the type needed for such a building subject to great vibration on account of the heavy printing press machinery, binders, etc.

THE CENTRAL TELEPHONE AND ELECTRIC COMPANY, 909 Market St., St. Louis, Mo., has issued its World's Fair art catalogue, No. 18, of telephone instruments and switchboards. The various styles of instruments manufactured by this company are clearly illustrated and their special features briefly described. On the right hand pages are shown views of the different principal buildings of the World's Fair. There are also shown some examples of the statuary used in the adornment of these structures.

THE EMERSON ELECTRIC MANUFACTURING COMPANY, St. Louis, Mo., in a recent bulletin, shows in illustration of and describes an electrically operated single-spindle slate drill press. The power of this machine is supplied by an Emerson direct-current ¼-hp motor, and is applied directly to the spindle. Another bulletin issued by the company gives the company's terms of sale and telegraph code. The code is very concise and comprehensive, and the idea of putting it in a separate bulletin is a good one.

THE MANHATTAN ELECTRICAL SUPPLY COMPANY, 32 Cortlandt St., New York, in its catalogue No. 16, just issued, shows a very extensive and varied line of electrical apparatus. About everything excepting dynamos is embraced in the list, which includes a very complete line of telegraph, telephone, electric light and construction supplies and novelties. Fan motors of different standard makes are also given due prominence. The catalogue is very comprehensive in scope, and it is surprising how much can be concentrated in 80 pages. It is very completely illustrated, and gives the prices of the multitude of articles described.

INDUSTRIAL RAILWAY CATALOGUE.—The C. W. Hunt Engineering Company, of West New Brighton, Staten Island, has just issued a very handsome new catalogue, to which it feels warranted in calling special attention as the most complete work of the kind that has been published. In addition to the large number of illustrations, showing the many and varied types of cars, standard and special, which the concern builds, the catalogue also contains much valuable information relating to the "Industrial" railway not to be found elsewhere, particularly of interest to engineers and architects. It will be of much use also to intending purchasers.

"MODERN METHODS" is the appropriate title of a very attractive and interesting pamphlet just issued by the North Electric Company, of Cleveland, O., as its Bulletin No. B-22. It contains 48 pages of text and illustrations and discusses on broad lines telephone policy, equipment, apparatus, management, etc. The admirable apparatus of the North Company is brought out in great detail, and the cuts must be highly commended for their wonderful clearness. The views of the complete switchboards are also excellent to a degree far beyond the ordinary. The handsome cover in colors shows a rural telephone line, and the interior of a busy exchange.

JEFFREY MACHINERY.—The Jeffrey Manufacturing Company, Columbus, O., has recently issued Catalogue No. 57a which will be of interest to certain lines of electrical manufacturing. It is on the subject of machinery for the saw-mill, lumber and wood-working industries. It gives a general idea of the company's elevating and conveying machinery, which can be adapted to almost every known industry. The catalogue is profusely illustrated with views of actual installations and of the apparatus and parts thereof. It contains 144 pages, which give a vast amount of information on the subject in general and specifically. The catalogue is gotten up in the company's usual first-class style, both as to arrangement and completeness.

UNIVERSAL ELECTRICAL DIRECTORY.—This valuable directory for 1904, issued by H. Alabaster, Gatehouse & Co., 4 Ludgate Hill, London, is a remarkable compilation, as usual. It contains the names and addresses of members of the electrical and allied trades and professions throughout the world, and is the oldest and largest electrical directory. It is divided into four sections, *i.e.*, British, with 11,560 names; Continental, with 9420 names; U. S. A., with 7500 names; Colonial, with 3610 names, making a total of 32,090. Each of these sections are again divided into alphabetical and classified sections, and in the case of the British a geographical section is also given. The entire book is carefully revised each year, and the financial information and central station particulars are brought up to date as far as possible.

THE FORT WAYNE ELECTRIC WORKS, Fort Wayne, Ind., have recently sent out a batch of trade literature. Bulletin No. 1051 contains a list of plants operating single-phase "Wood" alternators in the United States on Dec. 1, 1903. Bulletin No. 1052 is devoted to a description and illustrations of the multiple alternating current street arc lighting system. This is a very complete description of the system and is well illustrated with half-tone views of the apparatus and diagrams and curves showing connections and efficiencies. The Fort Wayne Works have also issued instruction books regarding their enclosed alternating current arc lamps of the multiple type and enclosed alternating current multiple system arc lamps of the special transformer type.

THE IMPROVED CINCINNATI AIR COMPRESSOR.—Bulletin L-508 of the Laidaw-Dunn-Gordon Company, of New York, bearing the foregoing title, is devoted to a new type of air compressor, the distinguishing feature of which is the novel manner in which the opening and closing of the exhaust ports are controlled. The exhaust opens through poppet valves, which is desirable, especially where the pressure pumped against is variable. The closing of the exhaust is determined by Corliss valves located in the passages between the cylinder and the poppet valves. These prevent all leakage of air back through the poppet valves while they are closing and also, by providing a cushion of air under full pressure, allow them to seat easily and without noise. The opening and closing of the admission are determined by the Corliss valves entirely.

THE TRIUMPH ELECTRIC COMPANY, Cincinnati, has issued a catalogue which—without indulging in a pun—can be designated as a triumph of the engravers' and printers' art. Moreover, the beauty of the production is enhanced by a lack of the striving for effect that often nullifies the object in view, the main factor in the success achieved being a well-balanced combination of excellent engraving and printing, well selected type and fine quality of paper. The few ornamental embellishments are properly subordinated, consisting of initial cuts, front and tail pieces. The catalogue describes and illustrates in detail the line of Triumph electrical machinery, and its application to various uses, direct-connected machine tools occupying considerable space. The half-tone engraving has most successfully stood the severe test entailed in representing this particular class of illustration.

POWER STATION SPECIALTIES.—This pamphlet describes power house auxiliary machinery for vacuum making and boiler feeding recently developed by the Geo. F. Blake Manufacturing Company, 114 Liberty St., New York City. The lists include rotary dry vacuum pumps, vertical cross-compound simplex boiler feed pumps, Admiralty type surface condensers with combined air and circulating pumps, vertical twin air pumps, comined pot-valve outside-packed-plunger duplex feed pumps and centrifugal pumps for circulating condenser water. This apparatus has been designed to meet the exact requirements of steam turbine and reciprocating engine units of 5000 to 10,000 hp capacity, using steam of 200 to 300 lbs. pressure per square inch. For the highest efficiency of each equipment, the vacuum must be as close to the barometer as mechanical means can produce, and it is to secure this end that the machines described in this pamphlet have been designed. The publication is numbered B-62, and will be sent upon request to those interested.

THE ELECTRICAL TESTING LABORATORIES, formerly known as Lamp Testing Bureau, have taken possession of their new quarters at 546 East 80th Street, New York City, and are now prepared to undertake many kinds of electrical and photometrical tests. All of the apparatus formerly installed at 4 Jay Street has been set up in the new laboratories, as also several new instruments which add much to their facilities. The equipment of these laboratories is most liberal and thoroughly up to date, while the technical staff consists of trained specialists and expert assistants. Tests made by the Electrical Testing Laboratories may be relied upon as being highly accurate and altogether satisfactory as to methods and thoroughness. All tests are treated with the strictest confidence, the data and reports being considered the property of the customer for whom the test is made, and are not available for the use of others. Tests are carried out with absolute impartiality, without favor to any one, and with the single object of accurately determining facts as they exist for the information of him who pays for the work.

IMPERIAL CROWN LAMPS.—The Bryan-Marsh Company has furnished us with advanced data as to its Impreial Crown lamp. This lamp consists essentially of the same component parts as the incandescent lamp. It is provided with an aluminum reflector fitting on the top of the bulb that increases the effective illumination and equalizes the distribution of light. It is designed expressly to meet the demand for a larger unit of illumination than afforded by the incandescent lamp where an arc lamp is inconvenient or unsatisfactory. The efficiency of the illumination of the Imperial Crown lamp is, it is claimed, greater than that secured from any other source. The light is uniform, steady, soft and perfectly diffused. The Imperial Crown lamp is suitable for use in connection with the most elaborate scheme of interior decoration. Its artistic outline lends grace and harmony to its surroundings. It is also suitable for concealed illumination and may be built into the walls or ceilings to conceal its outline without affecting its illuminating power. When thus concealed, it is unnoticed except for its light. The Imperial Crown lamp is furnished in two sizes with suitable fixtures.

Record of Electrical Patents.

UNITED STATES PATENTS ISSUED FEBRUARY 23, 1904.
[Conducted by Wm. A. Rosenbaum, Patent Attorney, 140 Nassau St., N. Y.]

752,589. ELECTROMAGNETIC REVERSING DEVICE; John Riddell, Schenectady, N. Y. App. filed May 28, 1900. Two oppositely rotating magnets for driving a planer, an armature located between them and a switch for throwing the circuit from one to the other at the end of each traverse of the table.

752,643. ELECTRIC PUMP FOR SWITCHING MECHANISMS; Walter J. Bell, Los Angeles, Cal. App. filed July 31, 1903. A solenoid magnet and an automatic circuit controller controlling the flow of oil to the cylinder of a motor which moves a railway switch.

752,649. TELEPHONE ATTACHMENT; George Briggs Buchanan, Haverstraw, N. Y. App. filed Sept. 15, 1902. (See page 476.)

752,659. SAFETY AND SIGNALING DEVICE FOR HOISTING MECHANISM; William N. Dickinson, Jr., Chicago, Ill. App. filed Jan. 4, 1902. A platform switch located at each landing of a dumb waiter, to prevent the car from being moved from any landing at which it is being loaded or unloaded.

752,689. ELECTRICALLY PROPELLED VEHICLE; Louis Krieger, Courbevoie, France. App. filed Feb. 26, 1903. A motor vehicle carrying a gas engine, a dynamo and an electric motor, the dynamo having shunt and series field coils wound in opposition, the series coil being wound to decrease the field excitation as the current increases. It is stated that as the intensity of the current depends upon the effort of traction, if this increases in consequence of an incline of the road, the difference of potential at the terminals of the dynamo at the same time decreases and the vehicle slows down automatically.

752,690. METHOD OF PRODUCING SPARKS IN THE CYLINDERS OF INTERNAL COMBUSTION ENGINES; Leon J. Le Pontois, New Rochelle, N. Y. App. filed Aug. 22, 1903. The method consists in simultaneously breaking two or more alternating currents, differing in phase from each other, thereby insuring a constant heat value of the spark at any given time.

752,691. INDUCTION ALTERNATOR; Leon J. Le Pontois, New Rochelle, N. Y. App. filed Aug. 22, 1903. A design for an alternator whereby sufficient current is produced at low speed to furnish a spark for starting an explosive engine, while at the higher speeds the armature reaction tends to maintain the current constant, notwithstanding speed variations.

752,692. POLYPHASE MAGNETO ALTERNATOR; Leon J. Le Pontois, New Rochelle, N. Y. App. filed Nov. 7, 1903. Details of construction of a generator designed to deliver two or more alternating current differing in phase from each other, such currents being employed for the purpose set forth in patent 752,690.

752,696. ELECTRIC CORD ADJUSTER; Jonathan E. Masterson, Spokane, Wash. App. filed May 23, 1903. A spring drum adapted to take up the slack.

752,705. AUDIPHONE RECEIVER; Hermann G. Pape, Brooklyn, N. Y. App. filed Oct. 21, 1902. (See page 476.)

752,710. MEANS FOR SYNCHRONIZING THE INSTRUMENTS OF TELEPHONE SYSTEMS; Hope Redmon, Rufust L. Hall and Robert H. Conway, Cynthiana, Ky. App. filed Sept. 17, 1903. (See page 476.)

752,719. AUTOMATIC SIGNALING SYSTEM FOR ELECTRIC RAILWAYS; Harry B. Snell, Cement City, Mich. App. filed July 17, 1903. A dial plate and index is located at each end of a block and operated to show motormen the number of cars in a block.

752,722. SWITCHBOARD; Alfred Stromberg, Chicago, Ill. App. filed May 13, 1902. (See page 476.)

752,834. ELECTRICAL RECEPTACLE; Philip H. Fielding, New York, N. Y. App. filed June 27, 1903. A receptacle adapted for application to the surface of a tubular wiring conduit, it having a projection carrying the binding screws which enters an orifice made through the wall of the conduit, enabling the wires therein to be attached without cutting and without exposed contacts.

752,839. SYSTEM OF ELECTRIC TRAIN LIGHTING; David C. Henry, Denver, Col. App. filed Sept. 23, 1901. A distribution system comprising a generator, a regulator consisting of two differentially-acting motors, a gear system and a variable resistance operated by the gear system and an automatic switch for including the motors in, or excluding them from, the circuit at predetermined voltages.

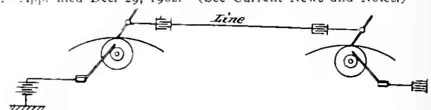
752,840. FLEXIBLE CONDUCTING-CORD; Howard B. Holmes, Evanston, Ill. App. filed Jan. 27, 1902. (See page 476.)

752,843. SIGNALING APPARATUS; Robert B. Kernohan, Pittsburg, Pa. App. filed May 23, 1903. A steam whistle is blown when the circuit is closed through a solenoid magnet.

752,844. MEANS FOR PROVIDING ZINC IN RADIATORS; William Raymond Kinnear, New York, N. Y. App. filed Sept. 8, 1903. (See page 476.)

752,865. ELECTRIC ARC LAMP; Carl Schuster and Christian N. Bergmann, Pittsburg, Pa. App. filed March 20, 1902. Details.

752,894. SELECTIVE SIGNALING; Reginald A. Fessenden, Fort Monroe Va. App. filed Dec. 29, 1902. (See Current News and Notes.)



752,923.—Electric Telegraph System.

752,895. SIGNALING BY ELECTROMAGNETIC WAVES; Reginald A. Fessenden, Pittsburg, Pa. App. filed March 14, 1903. (See Current News and Notes.)

752,909. TELEPHONE SIGNALING MECHANISM; Oscar Olsen Lee, Chicago, Ill. App. filed Jan. 11, 1900. (See page 476.)

752,921. AUDIPHONE-RECEIVER; Hermann G. Pape, Brooklyn, N. Y. App. filed Sept. 13, 1902. (See page 476.)

752,923. ELECTRIC TELEGRAPH SYSTEM; Charles Adams-Randall, New York, N. Y. App. filed Sept. 6, 1902. A single circuit line including transmitters and receivers and a source of energy, the circuit being open or mechanically ungrounded at one end and grounded at the other end.

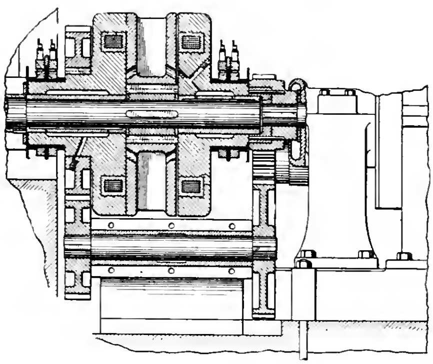
752,942. END-CELL SWITCH; John W. Achard, Philadelphia, Pa. App. filed May 17, 1902.

753,027. OSCILLATING ELECTRIC FAN; Jacob Amrom, New York, N. Y. App. filed June 27, 1903. The fan-carrying arms are oscillated in one direction by an electro-magnet and in the other by a spring, the invention consisting of the details of construction.

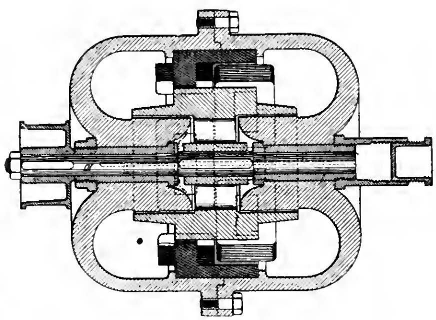
753,035. COMBINED PERCUSSION AND ELECTRIC PRIMER; Thomas G. Bennett and William Mason, New Haven, Conn. App. filed Nov. 23, 1903. The object is to produce a strong, reliable and sensitive primer constructed with particular reference to preventing the rearward escape of gas through leakage or piercing.

753,062. MICROPHONE; Pierre Germain, Fontenay Aux Roses, France. App. filed Oct. 7, 1899. (See page 476.)

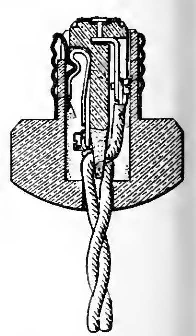
753,067. TELEPHONE OR TELEGRAPH SYSTEM; Robert Hamilton, Milton, Mass. App. filed Feb. 10, 1903. (See page 476.)



752,589.—Electromagnetic Reversing Device.



752,692.—Polyphase Magneto Alternator.



752,833.—Attachment Plug.

752,761. MULTIPLE-SWITCHBOARD SYSTEM; William M. Davis, Chicago, Ill. App. filed Dec. 7, 1900. (See page 476.)

752,812. ELECTRIC BLOCK SYSTEM; Charles W. S. Turner, Mountville, Va. App. filed April 3, 1903. Details of a system in which cars on the same block are able to communicate with each other.

752,820. DYNAMO-BRUSH; Max Bunnig, Gardelegen, Germany. App. filed Oct. 5, 1903. (See page 476.)

752,822. ALARM SIGNAL FOR RAILWAY TRAINS; Hugh E. Butler and Joab L. McCollum, Atlanta, Ga. App. filed Nov. 12, 1903. A cord extending through a train and connected with an alarm apparatus on the last car of the train which is set into operation by the breaking of the cord when the train separates.

752,824. ELECTRIC RAILWAY SWITCH; Harry H. Chandler, Waltham, Mass. App. filed Oct. 24, 1903. Details of a magnet for throwing a switch tongue.

752,833. ATTACHMENT PLUG; Philip H. Fielding, New York, N. Y. App. filed June 27, 1903. The connections with the flexible cord are made on a plug which passes into a central chamber in the attachment plug itself, thereby covering all of the contact screws but affording ready access thereto.

753,136. ALARM SYSTEM; John W. Hasburg, Chicago, Ill. App. filed July 23, 1903. Details.

753,138. PORTABLE ELECTRIC LAMP; Harry C. Hubbell, Brooklyn, N. Y. App. filed July 2, 1903.

753,157. RAILWAY BLOCK SYSTEM; Joseph Morton, New Westminster, Canada. App. filed Oct. 19, 1903. A signal man throws a projection at the track side into position to be struck by a corresponding projection on the train, to thereby operate an alarm on the train.

753,183. TELEPHONE SELECTING DEVICE; Willam D. Watkins, San Jose, Cal. App. filed Aug. 29, 1902. (See page 476.)

753,191. ELECTRIC METER; Thomas Duncan, Chicago, Ill. App. filed July 11, 1901. (See Current News and Notes.)

753,192. ELECTRIC METER; Thomas Duncan, Chicago, Ill. App. filed July 18, 1901. (See Current News and Notes.)

753,193. ELECTRIC METER; Thomas Duncan, Lafayette, Ind. App. filed Oct. 23, 1903. (See Current News and Notes.)

753,194. ELECTRIC METER; Thomas Duncan, Lafayette, Ind. App. filed Jan. 2, 1904. (See Current News and Notes.)

Electrical World and Engineer

THE CONSOLIDATION OF "THE ELECTRICAL WORLD" AND "ELECTRICAL ENGINEER."

VOL. XLIII. NEW YORK, SATURDAY, MARCH 12, 1904. No. 11.

ELECTRICAL WORLD AND ENGINEER.

Published weekly by the

McGRAW PUBLISHING CO.

114 LIBERTY STREET, NEW YORK.

NEW YORK, SATURDAY, MARCH 12, 1904.

CONTENTS.

A COMMEMORATIVE ISSUE.

The anniversary issue which we published last week celebrating the close of the first thirty years of existence of the ELECTRICAL WORLD AND ENGINEER and the beginning of its fourth decade, has been received in a most cordial and appreciative manner by our friends and readers, many of whom have been good enough to address us letters of congratulation upon the event and wishing us God-speed for the future. In doing so, several of them have expressed surprise at the size of the number, as well as at the variety of the contents and the quantity of advertising. These remarks and felicitations encourage us to make one or two notes as to the difference between the earliest issues of this journal and that of March 5. A comparison might be made with the old *Operator,* even more emphatic as to the growth of the journal, but it will suffice to give a few figures as to the first issue of January, 1883—when the paper became the *Operator and Electrical World*—and the last one just published.

Twenty-one years ago this journal, therefore, gratifying its worthy ambitions and rising from the status of a paper merely for operators to that of one covering the entire electrical field, although it had previously given a great deal of space to general electrical topics, was proud to call attention to the fact that it consisted of no fewer than 16 pages. Eight of these pages were devoted to text and eight to advertisements. As the form was then that of a folio, these pages were nearly twice the size of the present quarto, making, therefore, roughly, about 16 pages of text and 16 pages of advertisements. Last week the ELECTRICAL WORLD AND ENGINEER published 90 pages of text with a four-page supplement, and 196 pages of advertisements. In the first issue of January, 1883, the 16 pages of advertising contained 66 advertisements, including one or two of the publisher with regard to books. The last issue contained no fewer than 593 advertisements. The contrast between two such issues is indeed remarkable, but is only in keeping with the wonderful growth and expansion of the electrical arts in general.

THE DEVELOPMENT OF INDUSTRIAL ELECTROCHEMISTRY.

In the swift advancement of all branches of electrical engineering during the thirty years of the life of this journal, elecrochemical industries have vigorously participated only during the latter half of this period. It may perhaps not be surprising to read in Dr. Roeber's article published in our last issue that thirty years ago commercial electrochemistry was represented only by some branches of electroplating and by primary battery engineering; yet it is probably not generally known that the first American electrolytic copper refining plant was erected so recently as in 1882 while now 85 per cent. of all the pure copper of the world is electrolytically refined in this country. Most of the other electrochemical processes are of still more recent date. The electrical engineer has become intimately connected with electrochemical engineering by the introduction of the storage battery into central stations and sub-stations; he has there learned that electrochemical methods are the most suitable ones for storing electrical energy. But this storage of large amounts of energy is a feature also characteristic of the industries which represent the reverse problem of battery engineering, namely the production of chemical effects by electrical means.

A cursory review of these industries shows an astonishing variety of methods available for producing a certain chemical effect. We have electrothermic reactions in the electric furnace, electrolytic reactions, combinations of electrothermic and electrolytic reactions, and the methods of discharges through gases. To take a single case, to get caustic soda and bleaching powder from common salt, we have three essentially different classes of electrolysis of an aqueous solution of sodium chloride—the mercury cathode, diaphragm, and gravity processes—besides the electrolysis of fused salt with a lead cathode. All these processes are worked on a commercial scale and the classes of mercury cathode and diaphragm processes alone cover quite a number of essentially different methods. All these different processes, however, are characterized by one common feature, namely, that care is taken to keep the anodic and cathodic products of electrolysis separate from each other. That this is possible in so many different ways, characterizes the variety of electrochemical methods. On the other hand, if we provide means which facilitate the reaction between the anodic and cathodic products in the electrolysis of sodium chloride, we get hypochlorites or bleaching liquor. This shows how by an apparently slight modification of the process we get other products.

The effect of varying the result by changing the condition of the same experiment is perhaps most beautifully illustrated by the simple reaction between silica and carbon in the electric furnace, which may yield either carborundum or "white stuff" or silicon or graphite or silixicon. But while this example illustrates the enormous possibilities of electrochemical methods it also illustrates the inherent difficulties of electrochemical engineering, since it shows the necessity of carefully establishing and maintaining the proper conditions of operation in every process. The abundance in this country of valuable raw materials, and especially metals, to which electrochemical methods can be advantageously applied, coupled with the fact that our electrochemical and electrometallurgical engineers, every one of whom is a pioneer in a new field, are not working by the rule of thumb but according to exact principles, appears to fully justify the very high hopes entertained by those most competent to judge for the future of industrial electrochemistry. Here we believe will be a large part of the valuable work to be done during the next thirty years of this journal.

Thirty Years Progress in Electromagnetic Theory.

It is very interesting to consider the growth and development of electric theory during the past three decades. It has not been so much in the physical or pure theory as in the applied theory that the advance has been made. In the fundamental theory of the science, as reflected in the works of Gauss, Weber and Maxwell, thirty years ago, there is comparatively little increase; but in electrotechnical theory there has been a great advance and development. For example, the theory of the magnetic circuit has been developed during the last thirty years, and without this theory very little practical development could have been made in the art of constructing dynamos. All advances in construction would have been by empirical groping. Thirty years ago there was no alternating-current technology worth mentioning. Our recent industrial development of power transmission has rendered necessary an applied science of alternating-currents which is already extensive, and is constantly extending.

In the direction of electromagnetic waves, science has made notable advances in three decades. In that time the proposition has been set up and established that radiant energy is of electromagnetic nature, viz.: an oscillatory electromagnetic disturbance in the ether. Waves of radiant energy have been artificially produced by electric means with wave lengths as small as a few inches; but no artificial electric mechanism has yet been devised to produce wave lengths as short as a few microns, the condition necessary in order that the retina may respond, and the stimulus of light be produced. Of recent years the electronic theory has made great strides as a working hypothesis. It is still only in the stage of partial development. It is very comprehensive in its scope, since it may be said to offer an explanation of all matter, on the basis of electrical point sources in the ether. It also attempts to explain the phenomena of mechanical inertia, or the vis-inertia of matter, on the basis of self-induction in moving electrons; i. e., the moving charges that by postulation form matter. According to this theory, all electric charges are associated with ions or portions of atoms. No communication of electric charge can occur without the movement of such ions. Electric waves in free ether are, however, capable of carrying away the energy of such ions. All this theory has been created during less than thirty years, and if not yet demonstrated it must at least be admitted that each succeeding year gives more support to the theory.

Concerning the fundamental nature of electricity itself, there is still no certainty, but there are several hypotheses. There are several theories for explaining both electricity and magnetism in terms of the ether. None of these theories seem capable of being submitted to experimental demonstration. It is certain, however, that, since the interconnection between electricity and magnetism is known, a demonstration of the nature of the one must, by corollary, include a disclosure of the nature of the other. Moreover, it would now seem likely that the complete unraveling of the nature of electricity would necessarily include a revelation of the nature both of matter and of gravitation. All that can be said with reasonable certainty at present seems to be that electricity and magnetism are states of disturbance in the universal ether, although the exact kind of disturbance cannot yet be defined, partly because the mechanism of the ether itself must be sufficiently known in order to differentiate its disturbed conditions from its normal conditions. In the case of air, as an atmosphere on the surface of our globe, we have a sufficiently clear idea of its nature to enable us to say that a streaming disturbance of the air, necessarily accompanied by spinning or vorticity, constitutes the phenomenon that we all recognize as wind. Wind may, therefore, be defined as a particular disturbance of the air. Sound, as it reaches our ears, we attribute to a different kind of disturbance in air. So it seems clear, in like manner, that magnetism and electricity are particular disturbances in the ether. Just what the disturbances are is not clear. But we know that the two disturbances are mutually related in the manner that streaming is related to spin or vorticity in an incompressible fluid. Consequently, as the material for producing wind is always present, if we have suitable mechanism, say a fan, and power to drive it; so the material for producing electricity or magnetism is always present in the universal ether, if we have suitable mechanism, say a dynamo, and power to drive it.

Predetermination of Transformer Regulation.

The alternating-current transformer is a most useful and a marvelously simple machine for exchanging volts into amperes, when the terms of the statement are treated broadly, and not read through technically-adjusted spectacles. The transformer, however, has one objection, namely, that no practical plan of compounding it has yet been found. As the load comes on a so-called "constant-potential transformer," it forgets, to some extent, its duties to constant potential, in paying attention to the load. The pressure at terminals drops under load, like that of a shunt dynamo. The drop is small in large, well-constructed transformers, on non-inductive loads; but it is quite appreciable on inductive load, and, moreover, there is also the inevitable drop in secondary wiring. The result is that an automatically compounded transformer to maintain constant pressure under all loads at the mean distance lamp would be a great boon. Something might be done by suspending the secondary coil, and allowing it to approach the primary coil under load, as in the "tub-system"; but this would destroy the beautiful simplicity of the transformer mechanism. It is known that a constant-potential transformer, in addition to its pressure-varying properties, behaves like a single choking coil in the primary circuit. This proposition has been published in our columns. It is known that the resistance of the equivalent choking coil is the total resistance of the coils of the transformer, when reduced to a level transformer. It is also known that the inductance and reactance of the equivalent choking coil can be obtained from measurements made with short-circuited secondary.

In an article appearing on page 515 of this issue, Mr. E. G. Reed gives an empirical formula by which the inductance of the equivalent choking coil can be computed for a transformer of a particular type of construction. The formula involves the square of the number of primary turns and some geometrical relations that may be taken from the working drawings. This is a very convenient formula, and is given in one of the text-books on the subject. Mr. Reed gives a table of numerical data for a series of commercial core-type transformers, setting forth the inductances as computed in the above manner. The results are said to correspond very closely with the experimentally observed values. It appears from Mr. Reed's interesting table that the reactance factor of this line of transformers increases from 0.5 in 0.5-kw size, to 3.64 in 50-kw size. Also that above 10 kw the reactance factor very nearly follows a straight-line law, with respect to size of transformer, increasing 0.5 for every 10 kw. The reactance factor of this line of transformers, according to the table, may, in fact, be expressed, for sizes above 10 kw, by the equation $f = 1 + P/20$, where f is the reactance factor and P the capacity of the transformer in kilowatts. It is evident from an inspection of the values given in the table that the percentage resistance drop diminishes nearly according to a straight-line law beyond 20-kw capacity, being then expressed, approximately, by the equation, $n = 1.6 - 0.011 (P - 20)$. On the other hand, the reactance drop steadily increases with the capacity. This would mean that such transformers would regulate better in increasing sizes on non-inductive loads, but would not regulate better, and even somewhat worse, in increasing sizes, on heavily inductive loads.

HIGH-TENSION CONSTRUCTION.

Mr. Semenza's paper on this topic at the last Institute meeting is a most instructive presentation of the results following from European conditions. In almost every department of engineering the differing conditions here and abroad affect current practice deeply, and line construction is no exception to the rule. As the author very truly remarks, the importance of good line construction was slow to be recognized and insufficient precaution were taken against trouble. A few years served to teach the lesson of thoroughness, and line work as now carried out both here and abroad is reduced to a matter of careful and thorough engineering. But conditions vary from country to country and the practice advocated by Mr. Semenza would, we fear, generally lead to difficulties here. In the first place, they seem to have a curious fashion of figuring rights of way in Mr. Semenza's country, at so much per pole. Here it is generally regarded as very bad practice to secure anything less than a full right of way for complete access to the line at all times, and on important systems the right of way amounts to a considerable acreage. Preferably, we take to highways through our less settled and more heavily wooded country as the only way of securing proper access to the line without prohibitive expense. In either case, a full private right of way or utilization of a public way, there is nothing of any material account to be saved by increasing the span so far as cost of way is concerned. Then we are, of course, compelled here to face climatic difficulties to an extent unknown in Italy. Our extremes of temperature and the dangers from snow, sleet and wind are so serious that a factor of safety which would be permissible in a milder climate is quite out of the question here. This alone would account for many of the differences in line construction.

The ordinary American preference for rather thick wooden poles and rather short spans is mainly due to fear of the strength of long spans in our rather ferocious climate. We are just beginning to use long spans and steel towers, an extension of Mr. Semenza's methods, and their success here is still very problematical. Again, we are apparently able to get a far better wooden pole here than in Italy, for the life quoted by Mr. Semenza for wooden poles of two to ten years is far shorter than is found in American practice. In fact, ten years would be about the minimum life for wooden poles such as are used on the best American transmission lines, and it is an open question whether steel lattice poles would not be dangerously weakened by rust in a time not very much longer when exposed to a really bad sample of American climate. Again, on our long high-voltage lines running through a sparsely settled country, the insulating properties of wooden poles and cross arms are a valuable asset. Every manager of a transmission system can call to mind cases where an insulator has broken without serious results, the wire falling upon the cross arm harmlessly or with only inconsiderable burning, and staying in this position until repaired. A similar accident with a steel supporting structure would quite certainly put the line out of commission for some hours. Of course, in this connection the cross arm is more important than the pole, and steel poles, if they ever come into considerable use here, will quite certainly be used with wooden cross arms very thoroughly treated. In short, it seems very doubtful whether steel poles can be used under American conditions with any such advantage as is claimed for them by Mr. Semenza in Italian practice.

It would be very interesting to know the relative properties of American and European insulators. Here glass is used on some very high-tension lines with capital results, but as Mr. Semenza indicates, it is a material under suspicion as to durability. The cheaper labor abroad and the experience of many years in porcelain manufacture certainly should make it possible to obtain high-grade insulators far more cheaply there than here. On our great transmission systems the steady upward tendency of voltages keeps the insulator maker constantly upon the jump. No sooner does he standardize a good insulator for 30,000 volts than a call comes for an insulator to stand 50,000 or 60,000 volts. The present tendency in design of insulators is bad so far as successful production is concerned. Too much stress has been laid on dimensions in the mistaken notion that two square feet of bad insulating surface is better than one square foot of first-class material, and the result has been huge insulators of dimensions which make proper mixing and firing of the clay extremely difficult, and add new difficulties to line construction. Of the voltages now in use wide separation of the line is imperative and even at moderate voltages wide separation is advisable to lessen the chance of interruptions of service by wind-blown branches or by birds fouling the wires, and the weight of these big insulators becomes a rather serious matter. We like the insulator designs shown by Mr. Semenza. They seem well fitted to prevent surface leakage, and neither present undue surface to creeping discharges nor needless weight to render proper support difficult. The foreign practice, too, of cementing in the pins seems better than our common method of screwing them in, although in this connection it is of course not unusual to cement in pins here. In the electrical design of the lines Mr. Semenza follows much the same practice that is current here, although on most of our lines regulation is the controlling factor in the choice of line loss. As a practical problem, figuring the theoretical best cost of copper is a very troublesome proposition here on account of the very uncertain selling price of the energy transmitted.

Developments in the Allis-Chalmers Situation.
